APPOINTMENTS

FACULTY POSITIONS IN PHARMACOLOGY

The Department of Pharmacology at the University of Texas Southwestern Medical Center at Dallas seeks applicants for tenure-track positions at the level of assistant or associate professor Applicants must have a relevant Ph D. or M D degree and postdoctoral training and must show evidence of a firm commitment to a career in independent research We are particularly interested in applicants who plan to apply techniques of cellular or molecular biology or biochemistry to fundamental problems of pharmacological interest Responsibilities include teaching graduate and/or medical students after the first year of employment Send curriculum vitae, list of 3 referees and a brief description of proposed research to **Alfred G. Gilman, Chairman, Department of Pharmacology, University of Texas Southwestern Medical Center at Dallas, 5323 Harry Hines Boulevard, Dallas, Texas, 75235-9041.** *An Equal Opportunity/Affirmative Action Employer.* (NW4289)A

ATELIERS DE FORMATION
BIOMEDICAL RESEARCH

Aims	To focus on **recent advances** **To disseminate the most recent techniques** To provide a **personnaly tailored project**
Internationally chosen instructors	To gather EUROPEAN **researchers, technkians and teachers from research Institutes, Universities and Industry**
Two Stages	— Theory. **Evolution of critical assessments** — Practice · **Techniques-workshops**

21 ● Retroviral vectors for gene transfer

J L DARLIX (Toulouse), P M. LEHN (Paris), A WEBER-BENAROUS (Paris)

Critical assessments ● January 11-12, 1990 ● Paris

MAIN SPEAKERS M ALIZON (Paris), Y BARRANDON (Paris), M COLLINS (UK), O DANOS (Paris), S GISSELBRECHT (Paris), S GOFF (USA), R HEN (Strasbourg), B MALLISSEN (Marseille), A D MULLER (USA), R C MULLIGAN (USA), J F NICOLAS (Paris), A T PANGANIBAN (USA), M PIECHACZICK (Montpellier), Y SAMARUT (Lyon), E WAGNER (Austria), J WILSON (USA)

Number of participants . 80

Techniques workshops* · group training (20 persons maximum)

Deadline registration : november 15, 1989

22 ● Flow cytometry : illusions and realities, desappointments and perspectives

R MIGLIERINA (Paris), M H RATINAUD (Limoges), S BROWN (Gif-sur-Yvette) ; F LACOMBE (Bordeaux), E. MARTINI (Nantes)

Critical assessments ● January 16-17-18, 1990 ● Nantes (France)

MAIN SPEAKERS F BELLOC (Bordeaux), S BROWN (Gif s/Yvette), J L d'HAUTCOURT (Mons, Belgium), G FRELAT (Fontenay-aux-Roses), D GRUNWALD (Grenoble), J JONGKIND (Rotterdam, Netherlands), F LACOMBE (Bordeaux), M LALANDE (Boston, USA), E MARTINI (Nantes), P METEZEAU (Paris), R MIGLIERINA (Paris), M H RATINAUD (Limoges), Y REMVIKOS (Paris), A SEIGNEUR (Saclay), G VALET (Martinsried, FRG), J P VOINOT (Bordeaux)

Number of participants 60 maximum

Techniques workshop* individual training (20 persons maximum)

Deadline registration : november 22, 1989

23 ● Optical recording of transmembrane voltage in excitable cells

R FLORES-GUEVARA and J LOUVEL (Paris)

Critical assessments ● March 14-16, 1990 ● Paris (France)

MAIN SPEAKERS L COHEN (Yale Univ), M CATTARELLI (Lyon), B GODARD ISOPRA, Colombes), R HAUGLAND (Molecular Probes Inc , USA), J-M LEHN (Paris), L LETELLIER (Orsay), L LOEW (Connecticut), J LOUVEL (Paris), D RICHARD (Toulouse), M RIOULT (Bernel, W ROSS (New York), A ROSSET (ARCHIPEL, Annecy), P SAGGAU (Munich), B SALZBERG (Philadelphia), S TYC-DUMONT (Marseille)

Number of participants . 60 persons maximum

Techniques workshops* : individual training

Deadline registration : january 15, 1990

FORTHCOMING 1990

Physical mapping of large genomes
D. GRAUSZ (Paris), B. JORDAN (Marseille)
Critical assessments ● March 22-23-24, 1990
Techniques-workshop*

"In situ" hybridization of radioactive and non radioactive probes on chromosomes and interphase nuclei
M G MATTEI (Marseille), M. F ROUSSEAU-MERCK, E. VIEGAS-PEQUIGNOT (Paris)
Critical assessments ● April 26-27, 1990 ● Paris
Techniques-workshop*

Homologous recombination and in vivo directed mutagenesis
P BRULET (Paris), J L ROSSIGNOL (Orsay)
Critical assessments ● May 14-15, 1990 ● Le Vésinet
Techniques-workshop*

Transduction mechanisms and methods of second messengers and G proteins assays
A ENJALBERT, J PREMONT (Paris)
Critical assessments ● June 6-8, 1990 ● Le Vésinet
Techniques-workshop*

Animal models of human genetic diseases

Smith Kline & French Research Symposium

CHIRALITY IN DRUG DESIGN AND SYNTHESIS

27-28th March, 1990

ROBINSON COLLEGE, CAMBRIDGE, U.K.

The importance of considering the enantiomers of chiral drug molecules as separate species for the purposes of efficacy and toxicity studies is now clear. This has resulted in those involved in drug research having to face a new set of challenges in the regulatory, biological, and synthetic chemistry areas. The 1990 Symposium on *Chirality in Drug Design and Synthesis* will address these issues, with particular reference to the mechanism of action and synthesis of chiral compounds.

Proposed Programme:

1. INTRODUCTORY SESSION

Chairman: T. J. Rink, Welwyn
Speakers: J. B. Hook, Philadelphia
A. J. Ariens, Nijmegen
D. S. Davies, London

2. MECHANISTIC SESSION

Chairman: C. Brown, Welwyn
Speakers: D. Arigoni, Zurich
U. Hacksell, Uppsala
D. Williams, Cambridge

3. SYNTHESIS

Chairman: C. W. Rees, London
Speakers: S. M. Roberts, Exeter
P. Kocienski, Southampton
K. B. Sharpless, MIT

4. SYNTHESIS

Chairman: J. Cooper, Tonbridge
Speakers: I. Lantos, Philadelphia
S. G. Davies, Oxford
W. Oppolzer, Geneva

Poster Session: Posters are invited from participants and abstracts will be included in the Proceedings. Closing date for receipt of abstracts is *31st January 1990.*

Registration: Details are available from Mrs M. Worsley, Smith Kline & French Research Limited, The Frythe, Welwyn, Hertfordshire AL6 9AR. Telephone: (0707) 325111, ext. 3962.

The registration fee of £150.00 (£75.00 for registered undergraduate and graduate students) includes welcome buffet, conference dinner and all other meals, accommodation for two nights in Robinson College and a copy of the Symposium Proceedings.

Organising Committee: C. Brown, J. Cooper,* R. J. Ife and B. K. Leigh, Smith Kline & French Research Limited, The Frythe, Welwyn, Hertfordshire AL6 9AR; Telephone (0707) 325111.
*Smith Kline & French Research Limited, Old Powder Mills, Near Leigh, Tonbridge. Kent; Telephone: (0732) 833001.

2nd INTERNATIONAL SYMPOSIUM ON SUPERCONDUCTIVITY (ISS '89)

Date: November 14–17, 1989 Location: Tsukuba City, Ibaraki, Japan

ISTEC is planning its annual symposium to be co-sponsored by Ibaraki Prefecture.
Details of the symposium are as follows:

■ **Schedule:**

Tuesday 14 November
evening. Registration Welcome Party

Wednesday 15 November
Opening Session; *Plenary Lecture*
evening: Banquet

Thursday 16 November
Parallel Sessions & Poster Sessions

Friday 17 November
Parallel Sessions & Poster Sessions
afternoon: Closing Session, *Concluding Talk*

The symposium will focus on the following:

- ○ Physics and Chemistry, Theory, Characterization of Superconducting Materials and Their Properties.
- ○ Synthesis Processes of Superconducting Materials (Thin Film, Bulk, Tape and Wire).
- ○ Application (Electronics, Energy, Transportation, Medical and Accelerator).

○ Further Information is detailed in the Second Circular, available from the ISS '89 Secretariat.

Please contact:

ISS '89 Secretariat, ISTEC
Eishin Kaihatsu Bldg.
34-3, Shimbashi 5-chome
Minato-ku, Tokyo 105
Phone: 03-431-4002
Facsimile: 03-431-4044

(The official languages of the symposium are Japanese and English.)

COURSES & CONFERENCES

MOLECULAR BIOLOGY IN PHARMACOLOGY

A Course organized by the Steering Committee for the Federation of the European Pharmacological Societies

Milan, Italy, February 7-9, 1990

The Course will consist of lectures on molecular biology methodologies with particular emphasis on recent and future perspectives of their applications to pharmacology.

Scientific Secretary:
Adriana MAGGI
Milano Molecular Pharmacology Lab
Institute of Pharmacological Sciences,
University of Milan, Piazza Durante II
20139 Milan (Italy)
tel. (02) 288.45.67

For further information, please contact the secretarial office: **Dr. Ida Ceserani — "Molecular Biology in Pharmacology" — Institute of Pharmacological Sciences — Via Balzaretti 9 — 20133 Milan — Italy, tel. (02) 29404672 — fax: (02) 29404961.** (W6357)C

INSTITUTE OF PSYCHIATRY
UNIVERSITY OF LONDON

POST-EXPERIENCE COURSE IN NEUROSCIENCE

This evening lecture course is intended to provide a basic introduction to Neuroscience across a broad range of topics from molecular neurobiology to behavioural psychology Clinical topics on psychiatric and neurological disorders will also be covered

The course is aimed primarily at research workers (eg PhD students, technicians, postdoctoral researchers and clinicians) working in the neuroscience field but is open to anyone interested in broadening their background knowledge of Neuroscience. Major topics will be:

Neuroanatomy and Pathology
Neurochemistry/Neurophysiology/Neuropharmacology
Molecular Neurobiology and Neurogenetics
Behavioural Neuroscience
Neuroimmunology
Development and Degeneration of the Nervous System Vision
Computer Models of the Brain
Neurology and Psychiatry

The course will be held at the Institute of Psychiatry on Tuesday evenings in term time from 26th September, 1989 to 12th ne, 1990

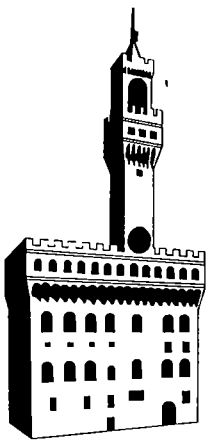
For further details please contact **The Secretar, Department of Neuroscience, Institute of Psychiatry, De Crespigny Park, London SE5 8AF.** Telephone 01 703 5411 Ext 3259 (1728)C

BIOTECH RIA '90

BIOTECHNOLOGY OF PLASMA PROTEINS: HAEMOSTASIS, THROMBOSIS AND IRON PROTEINS

FLORENCE, PALAZZO DEI CONGRESSI

APRIL 9-11, 1990



TOPICS

- ☐ Recombinant proteins involved in modulation of haemostasis
- ☐ Diagnostic applications of monoclonal antibodies in haemostasis and thrombosis
- ☐ New antiplatelet agents through biotechnology
- ☐ Biotechnology of clotting factors and fibrinolytic agents
- ☐ DNA probes for diagnosis of congenital defects
- ☐ Gene regulation on ferritin, transferrin and receptor
- ☐ Effect of proteins and iron on cellular proliferation and neoplastic transformation

CHAIRMEN
J.J. Sixma (Utrecht, The Netherlands)
P.M. Mannucci (Milan, Italy)
A. Albertini (Brescia, Italy)

(W6361)Q

8th General Conference of the European Physical Society

EPS-8

Amsterdam, The Netherlands, 4-8 September 1990

TRENDS IN PHYSICS

Subject of plenary talks (provisional):
Mesoscopic systems
Quantum crystals
Four years of high Tc superconductivity
The megabit chips
Diffractive microrelief structure
Light squeezing
Control of atomic motion with laser light
Single atom physics
Advances in magnetic plasma confinement
Neural networks
LEP: building operation and first results
50 years of the theory of everything
Fractals
Nuclear physics with electrons
Nuclei under extreme conditions
Millisecond pulsars
Magnetic fields in the sun and the stars

Subjects of symposia
High energy and particle physics:
I. Physics with LEP, SppS, Tevatron and SCC
II. Accelerator technology and control
Nuclear physics
I. Nuclear spectroscopy, Euroball
II Intermediate energy, heavy ions
Waves in plasmas
Non-classical states of electromagentic fields
Selected topics in atomic and molecular physics
Theory of correlated electron systems
Physics of low dimensional systems
Aggregates and clusters of atoms and molecules
Atomic scale scanning microscopy
Solar cells
Fibre optics
Order and chaos
History of physics
Physics for development (round table)

Exhibition: An industrial exhibition will be held during the conference with sufficient, easily accessible stand space available.

EPS

Conference Secretariat:

THE MACMILLAN MOLECULAR BIOLOGY SERIES

General Editor: Dr C J Skidmore, University of Reading

MACMILLAN MOLECULAR BIOLOGY

Genetic Elements in *Escherichia coli*

NEW

by Dr Peter Smith-Keary

Written for students of molecular genetics and molecular biology, the first volume in the series sets the scene by introducing aspects that provide the scientific background for the major technical advances of genetic engineering. Central topics such as replication, mapping, mutation, transposition and both general and site specific recombination are fully documented.

PB *0333 442687* **£9.95** HC *0333 442679* **£25.00**

Organelles

NEW

by Dr Mark Carroll

Aimed at second and third year undergraduate students following courses in biochemistry and cell biology, Organelles draws together the latest developments in our understanding of the ultrastructure and function of cell components. Each major cell organelle is the subject of one complete chapter, which ends with self-study questions to focus the reader on central concepts and principles. Throughout the book there are numerous micrographs and line illustrations.

PB *0333 44244X* **£9.95** HC *0333 442431* **£25.00** *(February 1989)*

Forthcoming titles include:

What is a Gene? by Dr C J Skidmore
Protein Biosynthesis by Dr R Jagus
The Molecules of the Cytoskeleton by Dr L Amos and Dr W B Amos

FLOW. AT THE HEART OF CELL BIOLOGY.

The nucleus of a living cell is small until viewed under the microscope, but its role in the maintenance and development of that cell is fundamental. Similarly, in the rapidly developing field of cell biology, there is, at its heart, a company which has emerged as a driving force and whose role is no less fundamental – Flow Laboratories.

As one of the first Cell Culture companies, Flow has used its extensive knowledge to develop and provide an unrivalled range of Cell Biology products including:-

MAMMALIAN CELL LINES

Flow hold the largest mammalian cell repository outside the USA. Primary, finite and established cell lines are exhaustively quality controlled and shipped directly all over the world.

CO_2 INCUBATORS

A wide range of water-jacketed and non-water jacketed cell culture incubators are available from Flow.

Continuous product development has led to our newest unit, the Digital Benchtop 1500, which offers state-of-the-art microprocessor control, solid heating elements and a unique Infra-Red CO_2 monitor.

MEDIA

As one of the world's largest producers of cell culture media, Flow can give the ultimate guarantee of quality. Media is supplied in either powder or liquid form together with a wide range of supplements and ancillary cell products.

CELL GROWTH PRODUCTS

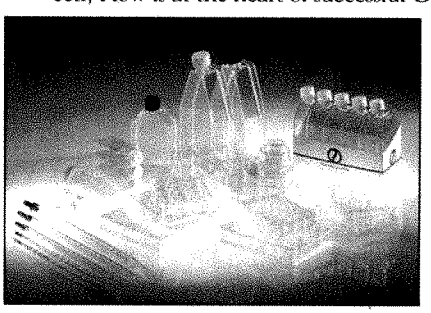
Flow offer a wide range of highest quality growth factors, lymphokines, serum substitutes and serum extenders. All products are stable, reliable, and of high activity, and purity.

SERA

Flow's global purchasing power ensures continuous supply of only the highest quality sera.

Sera are rigorously quality controlled to ensure biochemical consistency and freedom from all microbial contamination. Minimal endotoxin levels ensure applicability for all cell lines, particularly hybridomas.

Flow's lot reservation policy ensures continuity and consistency of supply. Orders are supplied with comprehensive physical and chemical profiles.



DISPOSABLE PLASTICWARE

The Flow Linbro® range of culture flasks, tubes, plates and pipettes provide the ultimate in high quality, economical tissue culture disposables.

As you see, unlike many Cell Culture companies, Flow supply all the products necessary to initiate and complete any tissue culture project.

A comprehensive supply capability.

So, as surely as the nucleus is at the heart of the cell, Flow is at the heart of successful Cell Biology.

Flow Laboratories

Flow Laboratories (Int.) SA., Sales and Marketing Headquarters, 6934 BIOGGIO, Centro Nord Sud, Switzerland.
Tel.: (41) (91) 595566 Telex: 844532 Floi Ch. Fax: (41) (91) 595569.

Flow Laboratories are located in Australia, Belgium, Canada, France, Italy, Japan, Netherlands, Switzerland, United Kingdom, United Stated of America and West Germany. In addition, Flow Laboratories have agent representation in over 120 countries worldwide.

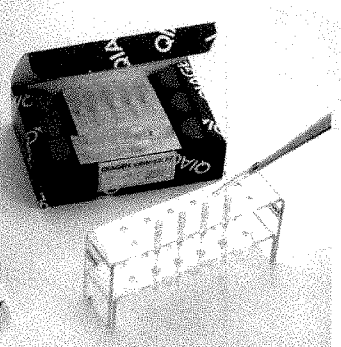
Hi purity lambda DNA

QIAGEN *Hi purity* >lambda< kits will dramatically change the way you isolate lambda DNA.
The QIAGEN >lambda< kit series represents a complete purification system. Lambda kits are available for either Mini, Midi, or Maxi preps of lambda DNA, containing all buffers, reagents, protocols and the QIAGEN mini columns.

QIAGEN means:

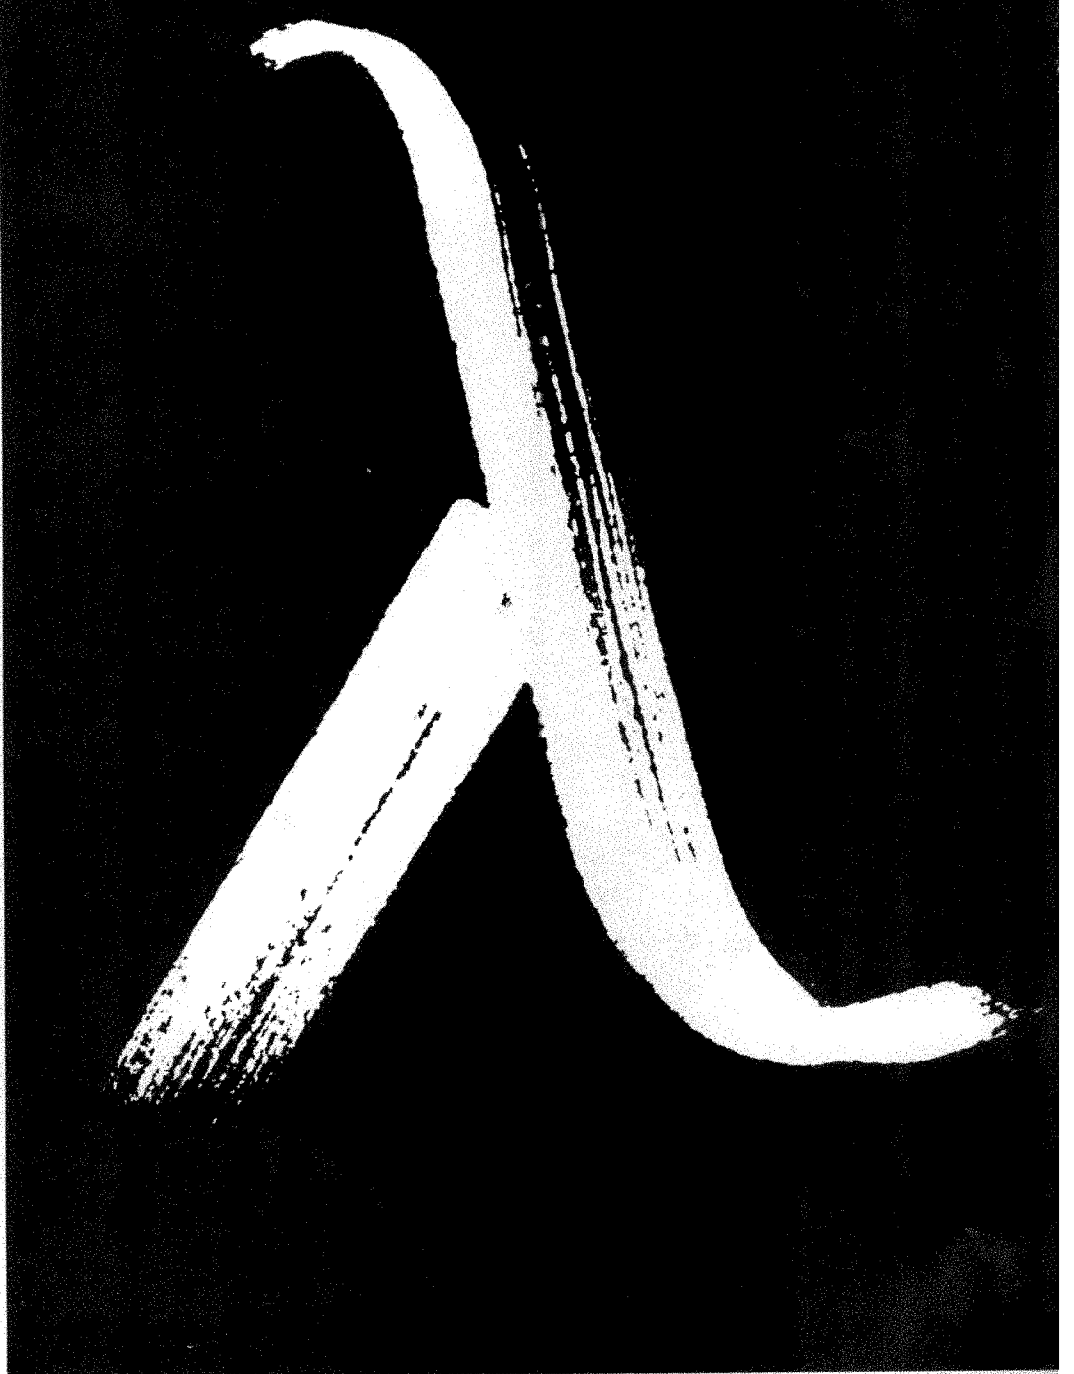
- **High Purity DNA**
- **Speed and Convenience**
- **No Phenol**
- **No CsCl or Ultracentrifugation**

With QIAGEN CsCl purity is equalled:



Pure lambda DNA can be isolated rapidly and economically using QIAGEN kits and easy-to-follow protocols. It is ideally suited for:

- **Cloning**
- **Enzymatic processing**
- **Sequencing**



QIAGEN mini columns

contain our unique-anion-exchange resin QIAGEN that guarantees the selective isolation of different classes of nucleic acids, and the complete removal of proteins, polysaccharides and metabolites.

QIAGEN kits are now available for plasmid DNA and lambda DNA

RESEARCH IN CELL CONTROL

MORE THAN A REMOTE POSSIBILITY

To keep your finger on the button in cellular control a wide range of Cytokine products is now available from British Bio-technology.

Designer Genes™, Designer Probes™, Proteins and Antibodies - tools to help you progress in your research.

Designer Genes™

Two types of Designer Gene ™ are available - fully designed genes can be expressed in *E. coli* whilst their natural counterparts may be expressed in eukaryotic systems or used as hybridisation probes.

Designer Genes
- all supplied as 10 ug lyophilised plasmid DNA

Human IL-1α	Human TNFβ
Human IL-1α (nat)	Human TNFβ (nat)
Human IL-1β	Human G-CSF
Human IL-1β (nat)	Human GM-CSF
Human IL-2	Murine GM-CSF
Human IL-2 (nat)	Human Acidic FGF
Human IL-3	Human Basic FGF
Murine IL-3	Human TGFα
Human IL-4	Human TGFβ$_1$
Murine IL-4	Human EGF
Human IL-5	Human βECGF
Human IL-6	Human IGF I
Murine IL-6	Human IGF II
Human IL-7	Human PDGF A Chain
Murine IL-7	Human PDGF B Chain
Human IL-8	Human IFNγ
Human TNFα	Human NGFβ
Human TNFα (nat)	Human Angiogenin

Quality control and protocol data is available.

Designer Probes ™

Designer Probes to Cytokines and Growth Factors are available as exon-specific probes or as Probe Cocktails which maximise sensitivity.

All probes are single stranded, of defined

length and sequence, and are suitable for Northern and Southern hybridisation, *in-situ* hybridisation and colony, plaque and dot blot hybridisation techniques.

Designer Probes
- All supplied as 1 ug lyophilised DNA

Human IL-1α	Human GM-CSF
Human IL-1β	Human TNFα
Human IL-2	Human TNFβ
Human IL-3	Human PDGF A
Human IL-4	Human PDGF B
Human IL-5	Human TGFβ_1
Human IL-6	Human Acidic FGF
Human G-CSF	Human Basic FGF

MURINE COUNTERPARTS TO ABOVE GENES AND PROBES WILL BE AVAILABLE SOON, please enquire for further details.

Proteins

British Bio-technology now have available a wide range of natural and recombinant Cytokine and growth factor proteins. The range is continually expanding - please enquire if your Cytokine of interest is not listed.

Natural Cytokines - range of pack sizes available	**Recombinant Cytokines**
Human TGFβ_1	Human IL-1α
Porcine TGFβ_1	Human IL-1β
Porcine TGFβ_2	Human IL-2
Porcine TGF$\beta_{1.2}$	Human IL-3
Human PDGF	Human IL-4
Porcine PDGF	Human IL-6
Bovine Acidic FGF	Human TNFα
Bovine Basic FGF	Human TNFβ

Cytokine Sampler Kit - sample sized quantities of the recombinant proteins available for initial testing purposes.

Antibodies

British Bio-technology has available a range of antibodies to detect the proteins and to neutralise the biological activity of the Cytokines.

Polyclonal Neutralising Antibodies

anti-Human IL-1α	anti-Human TNFβ
anti-Human IL-1β	anti-Human GM-CSF
anti-Human IL-2	anti-Porcine TGFβ
anti-Human IL-3	anti-Human PDGF
anti-Human IL-4	anti-Porcine PDGF
anti-Human IL-6	anti-Bovine Basic FGF
anti-Human TNFα	anti-Bovine Acidic FGF

Polyclonal Detection Antibodies	**Polyclonal Detection Kit**
anti-Porcine TGFβ	anti-Porcine TGFβ

Our range of antibodies is expanding rapidly as more Cytokine proteins become available for use as antigens, please contact British Bio-technology for further details.

BRITISH BIO-TECHNOLOGY - KEEPING YOU IN THE PICTURE WITH CYTOKINE RESEARCH

In the USA and Canada contact R & D Systems - Minneapolis 1-800-328-2400 for all products except Designer Genes.™ Please contact us for details of other local distributors.

Light speed signal

Enhanced chemiluminescent (ECL) immunoassay

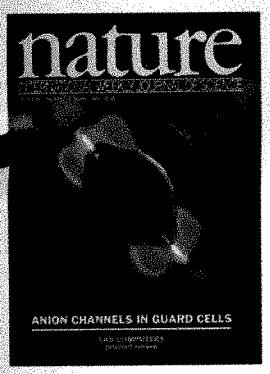
Amersham's Signal reagent brings the technology of enhanced chemiluminescence to peroxidase based immunoassay. It uses a specially developed enhancer to generate an intense light signal which offers sensitivities comparable with radioimmunoassay. Using Signal reagent couldn't be simpler. You just dissolve tablets A and B in the buffer provided and it is ready to add to the assay.

The signal is ready to read within 2 minutes of adding the reagent and stable for a further 20 minutes at least.

Amersham's Signal reagent was first developed for Amerlite, our proven diagnostic immunoassay system.

This breakthrough in non-radioactive detection is now available for your own immunoassay system.

Ordering code: NK8666. Sufficient for 2,880 standard tests.
For research use only.
Contents: 10 bottles buffer (30ml each). 10 tablets A. 10 tablets B.



Amerlite and Amersham are trademarks of Amersham International plc.

nature

5 October 1989
Vol. 341 Issue no. 6241

◀ A stoma in the epidermis of a broad bean (*Vicia faba*) leaf, photographed in polarized light through a red filter. The birefringence pattern is caused by the radial micellation in the cell walls, similar to the radial structures in a belted tyre. See page 450.

THIS WEEK

Ozone in winter

Polar stratospheric clouds, common features in the atmosphere above the South Pole, provide sites at which the photolytic chemical destruction of ozone can occur. On page 426, it is shown that ozone destruction may take place during winter in the absence of sunlight.

Nicotine inhibitors

Nicotinic receptors in the central nervous system have been implicated in Alzheimer's disease, the addictive properties of cigarette smoke, and seizure activity, but little is known about how nicotine alters the activity of CNS neurons. Activation of nicotinic receptors by agonists is normally associated with postsynaptic neuronal excitation. But intracellular measurements on rat dorsolateral septal nucleus neurons show the receptor can also mediate postsynaptic membrane hyperpolarization, leading to an *inhibition* of activity. Page 439

Look behind the ear

The hair cells of the inner ear can detect motions of atomic dimensions, and respond more than 1,000 times a second. In this week's Review Article, A. J. Hudspeth considers how these cells contribute to the functions of the ear, and discusses activities of the hair cells that are not yet understood. Page 397.

Mars on a plate?

The apparent lack of lateral offset of pre-existing martian craters or fault lines has led to the belief that Mars evolved without plate tectonics or other large-scale lateral motions of the lithosphere. Viking Orbiter images, however, reveal signs of strike-slip faults. On page 424, evidence is presented of lateral displacement of several kilometres, probably due to tectonic activity.

Neural developments

The vertebrate brain develops in a segmental pattern, with distinctive groups of neurons originating from different segments. In the mouse, the four Hox-2 homoeobox genes are expressed in the developing hindbrain with anterior limits set at two-segment intervals in a spatial sequence corresponding to the order of the genes on the chromosome (pages 405 and 382). Thus these murine *Hox* genes specify segment phenotype, as do their analogues in the fruitfly *Drosophila*. On page 442, an unusual *Drosophila* mutant is described. In the absence of a wild-type product from just one gene, called *shaggy*, all the cells in the embryo develop into neurons.

Out of the greenhouse

The response of vegetation to the considerable climatic variations of the past 1,000 years can give clues as to how ecosystems will develop if the anticipated global warming occurs. Vegetation in subarctic northern Canada is a test case, pages 429 and 384.

Model oncogene

Melanoma formation in *Xiphorus* fish hybrids provides a genetic system for the study of malignant melanoma in vertebrates. The *Tu* oncogene has been isolated and shown to encode a putative receptor tyrosine kinase related to the epidermal growth factor receptor produced by *erb-B* proto-oncogene. Article page 415.

In the frame

The structure of a short synthetic DNA containing a sequence known to be a hotspot of frameshift mutagenesis reveals a number of deviations from the standard B-DNA structure. Page 459.

Guide to Authors/Index

The Guide faces page 464. Also in this issue, the Author Index for Vol. 340.

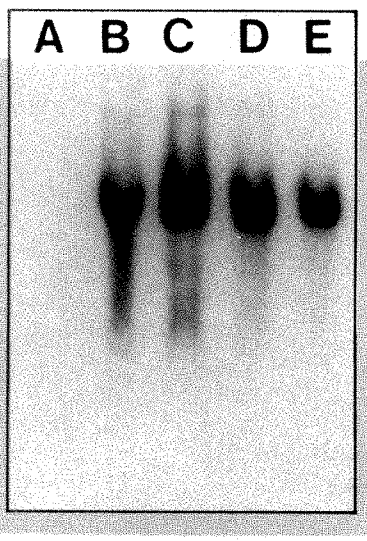
AND FAST.

Stratagene's Poly (A) Quik™ kit purifies polyA⁺ mRNA from total RNA in just minutes.

The ability to isolate messenger RNA molecules via polyA⁺ selection over Oligo (dT) cellulose has greatly facilitated the study of eukaryotic genes (1). Until recently, the protocol for Oligo (dT) cellulose chromatography involved the use of standard drip columns with a typical yield of only 1% mRNA (2).

Oligo (dT) spin columns were introduced to replace drip columns, reducing the total time required to 1 hour. Stratagene has now reduced that time to 15 minutes with the Poly (A) Quik™ push column.

Stratagene's new Poly (A) Quik™ kit allows rapid chromatography without the need for column preparation or centrifugation equipment. From start to finish, poly A⁺ RNA can be isolated from total eukaryotic RNA in less than 15 minutes with poly A⁺ yields equivalent to 2 to 3% of total RNA (3). Poly (A) Quik push columns and all of the necessary buffers are included within the kit.



For more info call Technical Services at 1-800-548-1113.

References

3. Dycaico, M. and Cramer, K. (1989). Stratagies 2.3:42.

Total RNA was extracted from transgenic and non-transgenic mouse liver using the Stratagene RNA isolation kit. One mg of transgenic total RNA was passed twice over a Poly (A) Quik™ push column, and the poly A⁺ fraction was purified. Samples were electrophoresed on a VAGE™ vertical formaldehyde agarose gel, vacuum blotted, UV cross linked, and hybridized to a DNA probe to detect the presence of the transgene.

A: 5 μg non-transgenic mouse liver total RNA.
B: 5 μg transgenic mouse liver total RNA.
C, D & E: 500, 175 and 75 ng of poly A⁺ enriched RNA from the Poly (A) Quik™ push column.

Comparing the signal intensity in lane B with lanes C-E, shows that the Poly (A) Quik™ push column enrich RNA sample for poly A⁺ species over 50 fold.

FROM START TO FINISH ...

As the race to bring biopharmaceutical products to market quickens, companies are closely examining their allocation of resources. Many have found that, whether they are developing recombinant proteins or monoclonal antibodies, there is good reason to use CELLTECH's experience in this field to increase the quality and certainty of their development programme and final manufactured product.

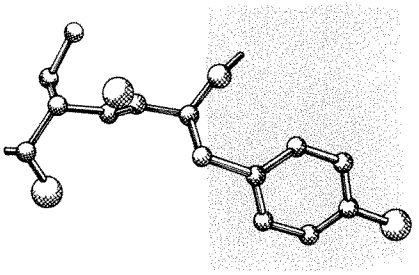
CELLTECH already provides many of the world's major pharmaceutical and biotech companies with specialist development and manufacturing services. These include:

- Mammalian and microbial cell line development
- Biopharmaceutical process and assay development
- Industrial and pilot scale manufacture of clinical grade biopharmaceuticals

With licensed products already being manufactured and further product licence applications under way, CELLTECH's track record of providing quality biopharmaceutical development services is outstanding.

Our **dedicated, industrial-scale manufacturing facilities,** utilizing airlift fermenters, give us a capacity of more than ten kilograms of product every year. This technology is compatible with hybridomas and recombinant mammalian cell lines – both of which are routinely grown in serum-free media to make therapeutic-grade product.

Nowhere is CELLTECH's attention to detail more effectively demonstrated than in **product assay development and process validation support.** These activities are essential to the manufacture of a consistent product, and become increasingly important as products reach the clinical trial stage. Our validation procedures include the following studies:



- Clearance of DNA, viruses, etc.
- Sensitivity of key process parameters
- Operation of purification columns
- Stability of process intermediates

All these studies require dedicated product assay development and support. Recent developments at CELLTECH include highly sensitive assays for murine and hamster DNA, and assays to demonstrate clearance of

ecific medium and host cell derived ntaminants.

All materials are manufactured under ll GMP guidelines. Our purpose-ilt manufacturing facilities have ccessfully passed inspection by regu-tory bodies on both sides of the tlantic.

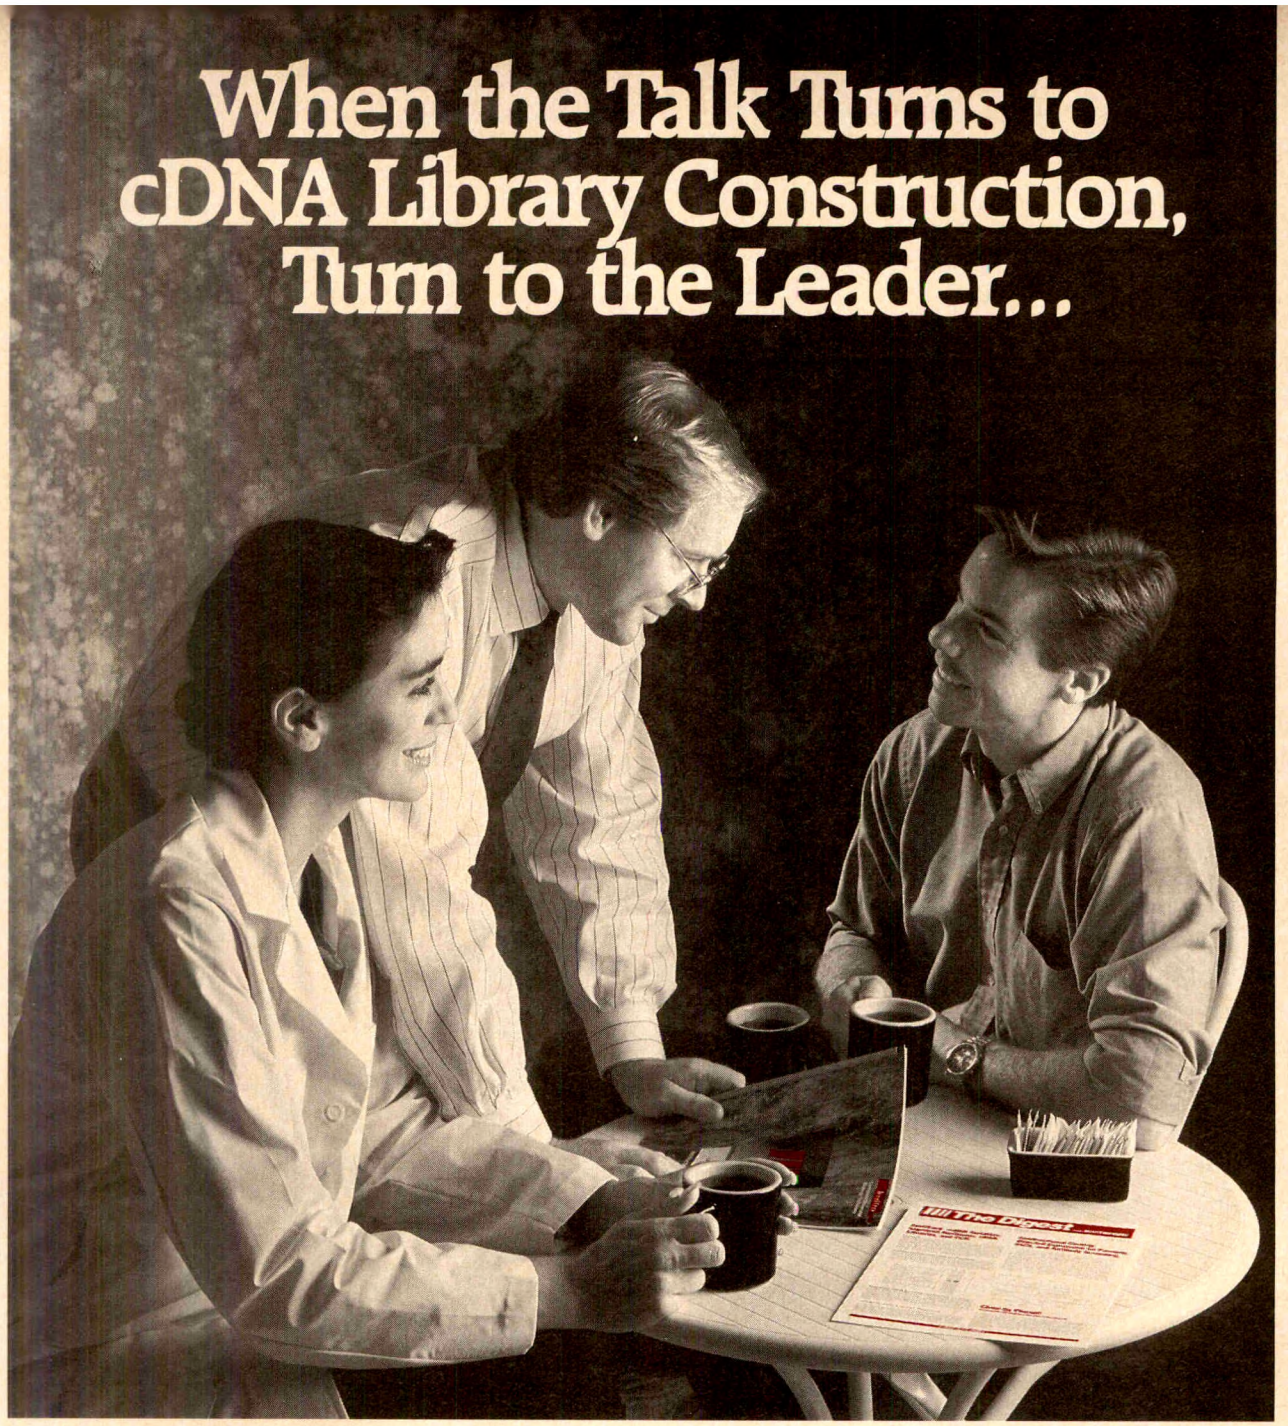
Comprehensive regulatory aware-ess and support have been obtained rough our accumu-ted experience with thorities throughout e world. As a result, r Regulatory Affairs am can help to ensure ccessful regulatory bmissions for products manufactured CELLTECH.

Biopharmaceutical manufacturing is rt of a comprehensive package of ser-ces which CELLTECH is able to pro-de to achieve the therapeutic potential your products. Additional **specialist rvices** that CELLTECH offers include:

- Protein engineering — construction of humanized antibodies
- Mammalian expression — development of highly productive CHO or myeloma lines using a proprietary gene amplification system
- Immunopurification reagents — development of faster, high performance protein recovery

CELLTECH has a firm financial base; it operates in the services business at a profit. This ensures that CELLTECH will remain a viable company, able to maintain its long-term commitments to biopharmaceutical customers.

As you plan the development, scale up, production, and clinical testing of your new biopharmaceutical, remember that CELLTECH is ready to meet all your needs for recombinant protein and antibody manufacture with proven technology and expertise.



To arrange a time for us to discuss your needs in complete confidence, contact Ian J. Nicholson or Susan J. Dexter at CELLTECH Limited, Riverbend Office Park, 9 Galen Street, Watertown, MA 02172, USA, or call 1-800-552-4934 or 617-923-4310 (Fax: 617-923-6480).

In Europe, contact CELLTECH Limited, 216 Bath Road, Slough, SL1 4EN, Berkshire, England, or phone UK (0753) 34655, International +44 753 34655 (Fax: (0753) 36632).

..CELLTECH WORKS FOR YOU

When the Talk Turns to cDNA Library Construction, Turn to the Leader...

...the Librarian from Invitrogen.

The Librarian family of cDNA library construction systems are versatile, easy to use, and are the only systems that contain all of the materials needed to take you from mRNA to recombinants.

The Librarians offer:

- Modular design that includes prepared vector, E. coli and all enzymes and reagents; quality controlled as a complete system for optimum efficiency;
- Your choice of mammalian, yeast, or prokaryotic expression vectors which simplify isolation, characterization and expression of cloned sequences;
- The convenience of functional screening, sequencing, mutagenesis and subtraction directly from libraries constructed in the Librarians phagemid vectors;
- A highly efficient method for size selecting cDNA generated by random or oligo dT priming;
- Technical service personnel with the experience to provide reliable information and assistance.

If you're talking about cDNA library construction and haven't talked to Invitrogen, it's time to pick up the phone.

T-Cell Epitope Determination
Cleavable Peptides Kit
available soon
Call now for details

Epitope Scanning & Mimotope Design Kits from Cambridge

Cambridge Research Biochemicals, under licence* from the Commonwealth Serum Laboratories, is offering a unique Multi-Pin Synthesis Technology which allows the concurrent synthesis and screening of hundreds of peptides in only a few days. Now any scientist can produce almost limitless numbers of novel peptides for immunological evaluation using ELISA-based systems.

The Epitope Scanning Kit permits identification of continuous epitopes within a protein antigen. All the possible sequential peptides derived from the protein sequence are synthesised. Peptides reacting with antibody are homologues of protein antigenic determinants.

The Mimotope Design Kit takes this technology one stage further, allowing the construction of novel peptide sequences capable of mimicking the actual epitopes of an antigen. Reactive peptides may have no homology to these epitopes and are therefore termed Mimotopes. Virtually any antigenic determinant may be mimicked by a synthetic peptide Mimotope.

Both Kits are supplied with extensive computer software support, a comprehensive materials and reagents package and a detailed instruction manual.

Contact our Technical Sales Department now for full details.

Now, a system for assaying gene regulatory elements

Send in the CAT

TLC analysis of CAT activity in extracts prepared from cells transfected with the following plasmids:

1. pCAT™-Basic
2. pCAT™-Enhancer
3. pCAT™-Promoter
4. pCAT™-Control

Introducing the new CAT reporter systems for the direct assay of your gene regulatory elements by measuring chloramphenicol acetyltransferase (CAT) activity.

CAT Assay System

- Simple Assays—buffer and cofactor provided
- Choice—TLC or liquid scintillation counting (LSC) analysis
- LSC Analysis
  - Quick—30 minutes assay
  - Sensitive and quantitative—detects broad range of enzyme activity (3 orders of magnitude)

Complete Set of Plasmids

- No Background—low endogenous CAT expression
- Identical Plasmid Contexts—related plasmid set allows quantitative comparisons
- Test Your Gene Regulatory Elements as a Unit or Separ
  - pCAT™-Basic Plasmid—no SV40 promoter or enhanc
  - pCAT™-Enhancer Plasmid—only the SV40 enhancer present; test your promoter strength
  - pCAT™-Promoter Plasmid—only the SV40 promoter present; test your enhancer activity
  - pCAT™-Control Plasmid—provides high levels of CA activity; control for transfection efficiencies and fo comparing promoter and enhancer strengths

ELECTRONIC RETINA FOR TRUE COLOUR AND FASTER ANALYSIS

A WORLD FIRST: LEITZ CBA8000

Real-colour image analysis that meets the most stringent requirements, combined with personal-computer convenience.

For the first time, a real-colour image-analysis system is now available for your microscope that applies the principles of our sense of sight.

The Leitz CBA8000 analyzes the colour, saturation, and intensity of each pixel. From these data, it determines size, shape, and distribution in a matter of seconds. Its unique active image probes and innovative analytical image-scan arithmetic disclose new relationships in your specimens in hitherto unequalled detail.

We'll gladly send you literature on the Leitz CBA8000.

To find out the difference between grey and real-colour image analysis, simply run this advertisement through your photocopier.

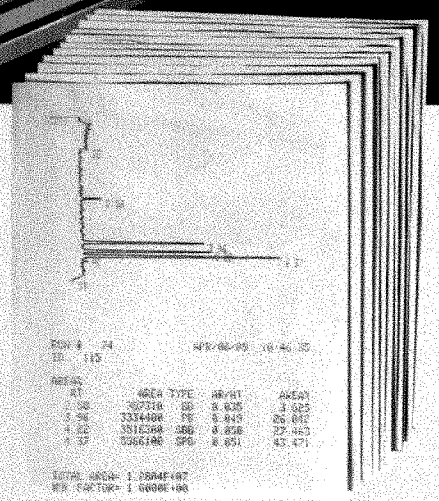
Beckman Sets the P/ACE for Automated Electrophoretic Separations...

Reproducibility

Nanoliter Samples



Femtomole Quantitation

Results in Minutes

High Resolution

The modular P/ACE™ System 2000 offers optional PC control for record archiving, link-up with mainframe LIMS-type system, and transfer to a program for publication-quality output. System Gold™ Chromatography Software provides easy-to-use data acquisition, integration and manipulation.

Shows 11 injections in 90 min from a total sample of 5 μL, accomplished with P/ACE.™ Migration time CV less than .25%.

The P/ACE™ System 2000 from Beckman is designed for today *and* tomorrow. A modular system, P/ACE leads the evolution of capillary electrophoresis.

A removable detector allows multiple future detection options. Interchangeable cartridges let you change capillaries in minutes. Temperature control provides unmatched reproducibility. And sealed vials minimize sample evaporation. All unique to P/ACE. Unique too—the surprisingly affordable price.

Keep P/ACE with the latest in electrophoretic separation techniques! And achieve rapid success separating proteins, peptides, synthetic oligonucleotides, DNA fragments, and more. Call 800/742-2345, or write to Beckman Instruments, Inc., Spinco Division, Customer Service Department, 1050 Page Mill Rd., Palo Alto, CA 94304. Offices in major cities worldwide.

A vector system that does more... only from Promega.

pGEM® Express System

U.S. Patent No. 4,766,072

The pGEM® Express system is based on the well known T7 expression system and Riboprobe® Gemini transcription *in vitro* system. The system's pGEMEX™-1 vector offers:

Many of the advantages of the pGEM plasmids:

- Efficient synthesis of RNA *in vitro*—opposed SP6/T3 RNA polymerase promoters
- Production of single-stranded DNA—phage f1 origin of replication
- Direct sequencing of DNA inserts—SP6/T3 RNA polymerase promoter priming sites

All of the advantages of the T7 expression system:

- High level expression in *E. coli*
- Ability to subclone lethal sequences and test for expression

And more...

- In-frame expression of your lambda gt11 clone in a plasmid
- Simplified purification of fusion protein (due to fusion of T7 gene 10 protein with insert)

The Division of Cancer Etiology

National Cancer Institute

Announces To the Scientific Community The Availability of the Following Resources/Services For Cancer Related Research As Noted Below:

Biological Resources

Avian Myeloblastosis Virus Reverse Transcriptase—2,000 Unit Minimum Order

Contact: Dr. G.E. Houts
Molecular Genetic Resources
6201 Johns Road, Suite 8
Tampa, Florida 33614
(813) 886-5338

Citing Contract #N01—CP—51007

Cost: $0.05/Unit
(Plus Shipping Outside Contiguous United States)

Goat Antisera Against: Avian, Bovine, Feline, Murine, and Primate Intact Viruses and Viral Proteins; Antibodies to Immunoglobulins for a number of species. Preimmune Sera available for some Virus Antisera.

Contact: Ms. Elizabeth Donley
BCB Repository
Microbiological Associates, Inc.
5221 River Road
Bethesda, MD 20816
(301) 657-8169

Citing Contract #N01—CP—61020

Cost: $75.00/5 ml. (Antisera)
25.00/5 ml. (Preimmune Sera)
100.00/50 ml. (Immunoglobulins)
(Frozen Material)

Cell Culture Identification Service. Using Isozyme Analysis, Immunofluorescence and Karyotypic Analysis (Chromosome Banding).

Contact: Dr. Ward Peterson
Children's Hospital of Michigan
3901 Beaubien Boulevard
Detroit, MI 48201
(313) 745-5570

Citing Contract #N01—CP—85645

Cost: $375/Analysis

Monoclonal Antibodies are available with specificities for synthetic peptides representing the amino acid sequences of the left end, right end and active site of the oncogene products of avian and mammalian retroviruses. Blocking peptides are also available, as are a limited number of cell lines producing the monoclonal antibodies.

Contact: Ms. Elizabeth Donley
BCB Repository
Microbiological Associates, Inc.
5221 River Road
Bethesda, MD 20816
(301) 657-8169

Citing Contract #N01—CP—61020

Cost: Peptides —$25.00/mg.
Ascites Fluid— 45.00/ml.
Cell Culture —100.00/culture.

(Plus Shipping and Handling)

Viruses: Avian, Feline, Murine, and Prim
Viruses Prepared in Tissue Culture.

Contact: Ms. Elizabeth Donley

Chemical Resources

Analytical resources for the collection, separation, and elucidation of the components of cigarette smoke and cigarette smoke condensates: A contractor with experience in the development of analytical methods for the determination of constituents of cigarette smoke and of specialty instrumentation for inhalation toxicology is available to assist qualified investigators with particular interest in studies on human and animal model exposure to environmental and sidestream smoke. A large inventory of reference experimental cigarettes, Standard Low Yield Reference Cigarettes, and an extensive chemical data base on smoke and smoke condensate components is available.

Contact: David G. Longfellow, Ph.D.
Chemical and Physical Carcinogenesis Branch

Executive Plaza North, Room 700
Bethesda, MD 20892
(301) 496-5471

Cost: Inquire

Chemical Carcinogen Reference Standard Repository: Reference quantities of over 750 compounds are available. The newest additions are dilute aqueous standards of PAH deoxyguanosine-3'-monophosphates for Randerath ^{32}p post labelling assays. Other classes of available compounds are: fecapentaenes, food mutagens, polynuclear aromatic hydrocarbons (PAH), PAH metabolites, radiolabeled PAH metabolites, nitrogen heterocycles, nitrosamines/nitrosamides, aromatic amines, aromatic amine metabolites, azo/azoxy aromatics, inorganics, nitroaromatics, pesticides, pharmaceuticals, natural products, dyes, dioxins and chlorinated aliphatics. Data sheets provided with the compounds include chemical and physical properties, analytical data, hazards, storage, and handling information. Catalog available upon request.

Executive Plaza North, Room 535
Bethesda, MD 20892

The Epidemiology and Biostatistics Program of the National Cancer Institute has developed the Observed versus Expected (O/E) software system which calculates. (1) the number of observed events (e g cancer cases or deaths) in a study group at risk, (2) the number of expected events in a study group based on the rate of occurrence in some standard or referent population; (3) the ratio of observed to expected events, and (4) the significance of this ratio The system is user friendly and capable of executing a series of calculations by different variables such as age, time group, date of exposure, age at date of exposure, duration of exposure, year relative to entry and cause of event The O/E System provides tables by race, sex and user defined variables, allows user defined latency intervals and accepts standard or user prepared rates O/E is written in COBOL and is exportable to most mainframes.

Human fibroblast cultures from individuals at high risk of cancer, members of cancer-pron families, and normal family members are available Collection is historical with unknown viability Catalogue unavailable. Information requests should include potential use of cultures

Biotechnology Serving Medicine

Medica Düsseldorf, the unique combination of international trade fair and scientific congress will provide an opportunity to examine latest developments in biotechnology and gene technology. For medical diagnosis and therapy. In addition, innovations in medical technology, pharmacy and information technology in medicine. More than 1,000 exhibitors from 24 countries, more than 800 delegates representing all specialisations and almost 100,000 qualified visitors from all over the world.

Exhibitor seminars offering practical advice.

New this year: Medica Juristica offering information about current legal issues affecting medical practitioners. Medica Doctors' Club, a centre for professional communication.

British universities fight back

After a long decade of attrition, British universities may have found a way (and the courage) to stand up to the government that has been their principal tormentor.

THIS year's retreat (to the city of Leeds) by the vice-chancellors (the leaders) of British universities seems to have been rewarding, even daring. The vice-chancellors have resolved to aim at financial autonomy of a kind. Faced with the government's belated but welcome conversion to the belief that a greater proportion of young Britons should follow degree-level courses, and its unwillingness to increase its subvention proportionately, they were even last week flirting with the notion of charging economic tuition fees to all students (see page 375), offsetting the burden on poor students by means of scholarships.

The future of this specific proposal is dubious, but it has brought the issue into the open, and is an excellent means of teasing a government still committed to the view that market forces are a universal emollient. If, the universities may argue, the public water supply and the electricity supply industries are being sold to private owners (see page 372), might not the government also welcome a free market in higher education? The difficulty, as all concerned know well enough, is that the government's political support is already over-sensitive to the cost of higher education. The much more modest proposal, in 1985, that well-to-do parents should pay nominal tuition fees on behalf of student offspring engendered a middle-class outcry and a humiliating retreat. It is unlikely that the same government will accept the vice-chancellors' more radical suggestion when the next general election may be only two years away.

Market forces

Yet something must be done. Part of the explanation for last week's hankering for independence by the universities stems from the realization that there will be no extra funds to cover the cost of the extra 6,000 students recruited to the universities this academic year. The government holds that its decision earlier in the year to double (to £800) the still-nominal tuition fees local authorities are required to pay on behalf of all degree-level students should be sufficient recompense. But the universities are also alarmed that only a kind of engineered chaos can follow from the ambition of the new conduit for public funds, called the Universities (no apostrophe) Funding Council (UFC), to require universities to bid against each other for public money with effect from the beginning of the 1990 academic year. That will be a market of a kind, but a manipulated market, with the UFC standing proxy for young people seeking an education. Why not — the logic seems to be — create a free market instead?

In the long run, something of that kind is unavoidable. The Secretary of State for Education and Science, Mr John McGregor, was right to remind the universities at Leeds that government subvention of the universities has increased by 9 per cent over the past decade (but student numbers have increased more quickly) and that the collective income of the universities from sources other than the government's higher education budget has increased from 10 to 25 per cent of the total (but much of this is research and contract income, which must be paid for by results). There is certainly no prospect that these trends could sustain an increase of the participation of young Britons in degree-level higher education in all kinds of institutions from 15 per cent (now) to McGregor's still-modest target of 23 per cent by the end of the century.

Scholarships

So how, in the real world, is a transition to autonomy to be arranged? One glaring defect of present arrangements is their uniformity. University salaries (accounting for more than 75 per cent of universities' costs) are nationally negotiated, while tuition fees and maintenance grants for students are fixed by the government. So universities are not genuinely in competition with each other in the true marketplace, that for teachers and that in which students make informed judgements of how they might best (and most economically) get the kind of education they need. The UFC bidding scheme is meant to be a step in that direction, but is hamhanded. The universities' scheme for coupling full economic fees (perhaps five times greater than those now charged) with a scholarship scheme would probably be unworkable, given the need to negotiate with more than 200,000 new students every year. But universities will have no way of measuring their efficiency while students are entirely insulated from the cost of teaching, which is why it would make sense if universities were allowed to charge their students modest fees, perhaps comparable with those now paid indirectly by the government. Among other things, that would test their ability and willingness to run imaginative scholarship schemes, which they could best do individually. □

Cultural chauvinism

Europe and the United States are haggling over airline ownership and television programmes.

EVERYBODY knows that the most cherished symbols of national sovereignty are a national airline and a television broadcasting network. In the 1960s, when independent governments were being created every few months, subsidized airlines and television stations were springing into being at a similar rate. Well-established governments, then, were scornful of this almost ritual hankering after the empty trappings of statehood. Yet it is now apparent that even the most mature governments are not immune from the same self-deception. How else can be explained the smouldering row between the United States and the governments of Western Europe over the ownership of US airlines and, separately, the content of European television broadcasts?

The circumstances are mystifying. Early in the decade, the Reagan administration decreed that US airlines should be deregulated in the sense that those with aircraft meeting specified standards of safety should be allowed to fly whichever routes they chose, charging whatever fares seemed to them to be economic. There followed a brief period during which new US airlines sprang into being and travellers were able to cross North America more cheaply by air than by any other means. But the prospect that competition would provide the smaller airlines with endless opportunities for growth proved hollow; those still surviving have mostly found niches as commuter and feeder airlines, while even the major US airlines have found their mutual competition financially debilitating.

That is partly why Northwest Airlines calculated that it could retain its independence only by seeking foreign investment (eagerly offered by the Netherlands airline KLM) and why the staff of United Airlines has teamed up with British Airways to buy the business from its present owners. But now, to everybody's consternation, the US Department of Transportation has decreed that KLM's proposed stake in Northwest Airlines must be reduced, casting a shadow on the British Airways deal as well. US law requires that no more than a quarter of the stock of US airlines should be owned by foreigners, but the US government has now taken the administrative view that foreigners must not acquire undue influence over US airlines by lending them money either.

The other side of this coin is the restriction of the content of television broadcasts proposed by the European Commission, with the enthusiastic support of several member governments of the European Community. Briefly, the commission proposes that only 15 per cent of the material broadcast by European television stations should come from outside Europe. Mrs Carla Hills, the US Trade Representative, has been in Europe lobbying against this intended regulation on behalf of the US television producers, whose business may be damaged if Western European television watchers cannot enjoy what has become their usual diet of US programmes.

Both arrangements are unreasonable restraints on trade, and should be openly recognized as such. The time has long since gone when commercial aircraft were essential components of a country's strategic power; to restrict foreign ownership is to restrict competition, thus ensuring that domestic travellers in the United States pay more than would be necessary. The proposed restriction of the foreign content of European television broadcasts will have the same effect; even when people do not have to pay for the privilege of watching television, extra costs will somehow have to be passed on. But is it not worth paying extra to retain Europe's cultural purity? That is the argument that beguiles governments, but can it make sense in a rapidly shrinking world? □

Sale delayed

The postponed timetable for selling Britain's electricity industry will increase uncertainty and reduce the price.

THE plan to sell Britain's electricity industry to private investors was never likely to be smoothly carried through, but the British government's decision last week that its timetable must be postponed by up to six months is a substantial setback, however much ministers may make light of it. There is a political risk; the timetable may now be so stretched out as to confuse the next general election. But there are important issues of principle still to be settled. Among other things, but to nobody's surprise, it is proving difficult to hammer out contractual arrangements between the supply companies, which are due to become retailers of electricity and which will be the first to be sold, and the generating companies, which will own existing power stations, which will be free to build more (as will be the supply companies) and will also enjoy the right to sell direct to industrial consumers of electricity.

That these questions are not simple goes without saying. Although the British government's intention seems to be that the balance between the supply and generating companies should eventually be determined by economics and market forces, the transition from the here-and-now must necessarily be somewhat prescribed. Otherwise, the uncertainties would make the chances of selling either of the two halves of the industry, let alone the National Grid (which is to be owned jointly by the supply companies), at a price reflecting the value of the assets being transferred, small indeed. Even as things stand, and with the government's undertaking to continue owning Britain's first generation of nuclear power stations (and thus to shoulder the substantial decommissioning costs that will eventually arise), the uncertainties are so great that the whole industry is likely to be sold for far less than its present economic value. Some of the eventual owners will profit handsomely, but guessing which they are is, on present showing, mere guesswork. □

Technology growth in French research budget

■ Industry gets money and tax benefits

■ Aviation and space rewarded

Paris

NUCLEAR technology in France is 'out' and space technology is 'in', if the 1990 civil research and development budget is any guide. In research minister Hubert Curien's second budget of his second term, only the atomic energy centre (CEA), having "reached maturity", has seen its research funding drop. Against an overall civil budget increase of 7.1 per cent to FF45,353 million ($7,100 million), CEA loses 4 per cent, and for the first time state spending on space, through both the national space research centre (CNES) and contributions to the European Space Agency (ESA), has overtaken spending on nuclear energy research.

France once had a goal of spending 3 per cent of its gross domestic product on research and development by 1992. Last year the figure was 2.34 per cent, and Curien hopes it will rise to 2.38 per cent next year. But if the date has been dropped, the goal remains, and in this budget, industry is being coaxed into spending more on research, with high-technology projects most likely to win government approval.

The government's expansiveness has been offset by slow overall growth in the economy, a call for strict housekeeping and reductions in the growth of spending on defence and nuclear energy research. France is also reducing its high rate of value-added tax, to bring it in line with other European countries before 1992. The loss of tax revenue means that the gamble that the economy will grow through the support of industry and technology must pay off.

Industry will receive a total of FF5,000 million in benefits, partly in the form of extended tax concessions for research and development (FF2,600 million last year). There will be a 30 per cent increase (to FF1,566 million) in the national technology research fund (FRT) which supports emerging areas such as new materials and biotechnology, and through the industry ministry FF843 million, more than three times last year's sum, will go towards technology innovation, such as the European JESSI superconductor programme and the EUREKA high-definition television venture.

Also on the commercial front, this summer's decision to back a fourth-generation of the SPOT remote-sensing satellite has led to FF352 million being set aside next year out of the expected total cost of FF2,500 million. France is a also major contributor to the ESA space effort: 45 per cent of the cost of the Ariane-5 launcher will come from the French and this, in 1990, will cost them FF1,812 million. The Hermès shuttle and France's contribution to the Columbus space station account for a further FF747 million destined for ESA next year.

A 16.6 per cent increase for research in aviation technology, to FF2,882.6 million, goes mostly to the successful Airbus civil aeroplane, new engines and a helicopter. But the go-ahead has been given for preliminary research into hypersonic passenger flight to develop a competitor to Britain's revolutionary, if neglected, HOTOL space-plane and the West German Sänger equivalent.

Basic research was given less emphasis in Curien's budget presentation but has not been left out. The *'grands organismes'*, such as the National Centre for Scientific Research (CNRS) and the National Institute for Health and Medical Research (INSERM) between them account for 53 per cent of the civil research budget and in 1990 there will be increases of between 4.6 and 6.9 per cent for CNRS. The laboratory bench receives priority in the raises: salaries and money for equipment go up, and 432 new research posts and 318 technical and support jobs are being created.

The CNRS, the largest state research employer, gets the biggest share, with FF10,331 million and 305 new jobs. The INSERM grant for 1990 will be FF1,825 million, a 5.6 per cent increase, with 88 new jobs. The Pasteur Institutes in Paris, Lille and in French overseas departments will also have 10 per cent more to spend (a total of FF375 million from the state), with the overseas accent on parasitology and research to combat malaria. The environment, particularly research into climatic stability and the ozone layer, will benefit from an extra 13 per cent for the environment ministry and a 30 per cent increase for meteorology.

As in 1989, AIDS research remains "a priority", with a total FF180 million support for the national AIDS research agency (ANRS), in addition to that available within the major state research organizations. About 58 per cent of ANRS grants will go on basic research, 34 per cent on clinical and epidemiological research — including a major survey of sexual habits in France — and the remainder on public health, social and human sciences research. **Peter Coles**

NEWS IN BRIEF

Great le(a)p forward

London

PHYSICISTS at the European particle physics laboratory CERN are jubilant at the success of the first two weeks of experimental runs on the Large Electron–Positron Collider (LEP). With more than 4,000 Z^0 particles detected, they are already preparing their first analyses of this fundamental particle. Before LEP started, only 700 Z^0s had been detected in all experiments since 1983. Thus, expectations raised at the first trial runs in August, when LEP's first Z^0 was detected after only 15 minutes even though the apparatus was not fully tuned, are being fulfilled. On a good day, 400 Z^0s can be detected, and further technical improvements should raise this count rate by another factor of 10. By comparison, it is pointed out, the Stanford Linear Collider, previously the leading accelerator in these studies, averages 10 Z^0s a day.

The LEP data are already sufficient to supersede the SLC measurement of the width of the Z^0 resonance — the range of collision energies over which Z^0s are produced. Eventually, it is hoped, this parameter will reveal several fundamental features of physics, including the number of neutrino types and the masses of the top quark and Higgs boson. R.P.

Exiles' new foundation

Paris

CHINESE student leader Wuer Kaixi and an academic, Yan Jiaqui, were 10 days ago at the centre of the largest meeting of dissidents in exile since the Tianamen Square massacre on 4 June. Some 167 delegates from different countries — including Hong Kong and Taiwan — and over 200 other participants were present at the Paris Sorbonne to launch a Foundation for Democracy in China. The foundation is headed by Yan Jiaqui and Wuer Kaixi and a 15-member council. Its aim is to form an international focus for opposition to the incumbent Chinese government. P.C.

More home comforts

Bangalore

As part of a government effort to persuade Indian scientists working abroad to return home, a scheme called the Transfer of Know-how Through Expatriate Nationals (TOKTEN) has been launched by the Council of Scientific and Industrial Research Money will be available to pay for qualified expatriates to visit Indian academic institutions and industries, in the hope of generating immediate gains for the host institution as well as promoting links that might draw an expatriate back.

The scheme also aims to find temporary placements for returning scientists and technologists. The creation of new posts is being considered, as are methods for assisting non-resident Indians with the importation of laboratory equipment. R.R.

GALILEO MISSION

Plutonium generates opposition

Washington

A COALITION of environmentalist and anti-nuclear groups is asking for a legal injunction to prevent the launch on 12 October of the space shuttle Atlantis, whose payload is the Jupiter-bound spacecraft Galileo. A lawsuit filed in the District of Columbia last Thursday claims that the National Aeronautics and Space Administration (NASA) has deliberately underestimated the chances of a launch accident which could release some of the 100 kg of plutonium that Galileo carries to generate power. But those behind the lawsuit would not say whether a reassessment of the risks could even in principle lead to an outcome they would find acceptable, and said that if legal efforts to stop the launch failed they would mount a programme of civil disobedience.

During Galileo's 22-month mission, it will study at close range both Jupiter and several of its satellites, and will drop a probe into the jovian atmosphere. To provide power for its many scientific instruments, it carries two radioisotope thermal generators (RTGs), each containing about 50 kg of plutonium in the form of $^{238}PuO_2$. The RTGs are not nuclear reactors; radioactive decay of the plutonium dioxide, made up into a number of 5-cm-long fuel pellets sealed into iridium and carbon-boron epoxy-fibre capsules, releases heat which is converted into electric power by thermocouples. Plutonium is used because it emits mostly alpha-radiation, easily captured by the shielding and converted to heat, and little of the more penetrating and more dangerous gamma-radiation.

The lawsuit raises the possibility that if Atlantis, like Challenger almost four years ago, were to explode on launch, the RTGs could be blown apart, scattering plutonium powder across Florida. NASA, on the other hand, says that the RTGs have been physically tested, and shown to remain intact, under conditions more severe than a shuttle explosion.

The groups asking for the injunction are the Florida Coalition for Peace and Justice, an association of local groups active in human rights and anti-nuclear campaigning, the Washington-based Foundation for Economic Trends, led by Jeremy Rifkin, which has lobbied and litigated over many environmental issues, and the Christic Institute. The last of these is an idiosyncratic Washington organization with a history of involvement in anti-nuclear activities, such as the Karen Silkwood case and the radiation leak from the Three Mile Island reactor, but which is also known for its theory that US foreign policy, since the late 1950s, has been steered by a cabal of CIA (Central Intelligence Agency) and ex-CIA operatives of whom Oliver North is but the latest.

At a press conference to announce the filing of the lawsuit, Bruce Gagnon of the Florida Coalition, Rifkin and Lanny Sinkin of the Christic Institute quoted a variety of different numbers that they said NASA had used at different times for the probabilities of certain kinds of accident. Before the Challenger disaster, they said, the chance of a shuttle explosion had been put at one in 10 million; now it was as high as one in 35. NASA put the chance of plutonium release at one in 2,500, but other official numbers given by Rifkin led to a figure of one in 430. Moreover, it was argued, NASA has suppressed risk assessments that disagreed markedly with its own, and has failed to include all relevant analyses in its Environmental Impact Statement for the Galileo mission.

The lawsuit thus argues that NASA has evaded its responsibilities under the 1982 National Environment Protection Act, and seeks to have the risk assessment analysis re-done, with all facts and figures made public. But, at the press conference, the ultimate purpose of this legal tactic was not clear. Neither Rifkin, Sinkin nor Gagnon would say what probability of plutonium release, determined by a new risk assessment, they would find acceptable. Sinkin likened an Environmental Impact Statement to a risk-benefit analysis; in this case, he suggested, the risk was clearly finite and the benefit, at least to the people of Florida, was nil.

Moving on to larger themes, Sinkin said that the "radioactivists" — his name for the Department of Energy (DoE), which supplies the plutonium to NASA — were bent on putting radioactive materials into space wherever they could. The purpose of this strategy, said Gagnon, was that by using civil missions such as Galileo to launch nuclear devices without arousing great public anxiety, the path would be cleared for the true ambition of DoE and the weapons industry, which was to put nuclear weapons into space.

Sinkin, Gagnon and Rifkin all argued that NASA's reliance on nuclear power for long-term missions far from the Sun could be changed if they were forbidden to use plutonium or other radioisotopes; they would be forced to find alternatives. It might take 10 or 15 years, Sinkin said, but Jupiter "would still be there".

The official response to the lawsuit, which names President Bush as well as NASA and DoE, will come through the Justice Department. A statement from NASA claimed that the press announcement of the lawsuit contained several "glaring inaccuracies", and a spokesman said that the reason that a variety of accident probabilities were in circulation was that there was no single way that plutonium might be released — an explosion on the launch pad and one five minutes into the flight would have quite different consequences, for example — and a suitable average of different probabilities had to be determined. For now, NASA is standing firmly by its estimate of 1 in 2,500 as the chance of a release of plutonium during the launch of Atlantis.

David Lindley

PUBLIC HEALTH

Are video terminals dangerous?

Boston

ALMOST four years after it was first proposed, the Mount Sinai School of Medicine in New York has begun a comprehensive, nationwide study intended to provide answers to long-standing questions about the reproductive risk to women office-workers of constant exposure to video display terminals (VDTs). The four-year, $2-million study began officially last month with funds from the National Institute of Child Health and Human Development.

Michele Marcus, the principal investigator, says the study "will examine the lifestyles, work activities, and health of 8,000 women office workers nationwide". Participants in four cities (New York, Boston, Cleveland and an as yet undetermined city in California) will be assessed by questionnaire, and 800 of the 8,000 will then be monitored closely for one-year during which time the women's menstrual cycles and hormone levels will be monitored, and their urine will be tested for human chorionic gonadotropin as a sensitive indicator of pregnancy. Provided that some of these 800 women become pregnant during the course of a year, the Mount Sinai study will be the first to monitor women office workers before pregnancy and throughout the first few months. Such a method seeks to control biases that have made questionable the results of some earlier studies. One such study, completed last year at the Kaiser Permanente Medical Center in California, found that women who used VDTs for over 20 hours per week had twice the miscarriage rate of those who did other work.

Louis Slesin, editor of the trade newsletter *Microwave News*, praises the Mount Sinai project and is happy to see the issue receiving federal support. Although the reality of the dangers of VDTs remains highly controversial, Slesin says that the Kaiser Permanente study "made the potential health risks credible", but adds that the Mount Sinai study, when it is completed in 1993, should provide a much fuller picture.

Seth Shulman

MEAT RESEARCH

Third World aid for Bristol?

Tokyo

WHEN a British research institute faced with the prospect of closure by the government recently sent out an international appeal for help, assistance in the form of money intended as aid for developing countries was probably the last thing expected. But that, by way of Japan, is what may come.

In July, A. A. Taylor of the Bristol Laboratory of the Agriculture and Food Research Council (AFRC), formerly the Meat Research Institute, sent a number of letters to colleagues overseas explaining that the British government intended to shut down the laboratory at the end of 1990, and asking for letters of support as a means of persuading the government to keep the laboratory open. One of these letters went to Keiji Umeda, director of the Food Engineering Division of the National Food Research Institute in Tsukuba near Tokyo.

In reply, Umeda suggested that the Bristol Laboratory should apply for Japanese Overseas Development Assistance (ODA) on the grounds that the laboratory could make a good training centre for Africans and Eastern Europeans. Umeda pointed out that the Japanese government announced thousands of millions of dollars in increased aid for

Africa and Eastern Europe at the Western Economic Summit in Paris in July, and that in the 1990s these countries more than any others will be in need of technical guidance and assistance in meat research. But Japan lacks expertise on Africa and Eastern Europe. He suggested that Taylor should contact the Japanese Crown Agents in London, which handle Japanese grant aid, to offer the laboratory's assistance.

The Bristol Laboratory is one of three AFRC laboratories that grew out of the Low Temperature Research Station in Cambridge. It carries out research on meat from slaughter through refrigeration, processing, packaging, on microbiology and quality assessment, along with basic research on muscle biology. It is considered a center of excellence by meat researchers around the world. But the UK government has decided that the meat industry should pay for the laboratory's research, and is cutting off support.

In his letter to Taylor, Umeda says that "the expertise in meat research at Bristol will never lose its importance for the rest of the world, even if the United Kingdom may not need government research any longer". According to Kiyoaki Kato, a colleague of Umeda's at the National Food Research Institute, Umeda spent "very happy days" at the Low Temperature Research Institute in Cambridge in the 1950s, and his suggestion that the Bristol Laboratory apply for ODA money is just "friendly advice".

In Britain, the *Guardian* newspaper has suggested that the aid deal could be used by Japan as a "springboard into new markets in Eastern Europe and Africa, in competition with Britain". But Kato denies any such motive, saying Eastern Europe is too poor to import meat from the West or Japan. These nations desperately need to develop domestic production because meat supply is "vital to social stability". And as for Africa, Kato says, Umeda's intention is that the Bristol laboratory should link up with several international agricultural research centres in Africa that are also funded by ODA.

Taylor has contacted the Crown Agents. In a letter to Umeda on 6 September he says that although there does not seem to be much hope, the Crown Agents have requested more details, and adds "perhaps, now that Japanese companies own our motor industry, you can buy the institute". **David Swinbanks**

BRITISH UNIVERSITIES

Who pays for students?

London

GOVERNMENT plans to increase the number of British students in higher education were given a welcome by the Committee of Vice-Chancellors and Principals (CVCP) following their annual meeting at the University of Leeds. But the university leaders warned that expansion without increased Treasury support, as the government proposes, could mean that students would somehow have to pay their own tuition fees.

The need for a new system of student financing emerged as John MacGregor, the Secretary of State for Education and Science, reiterated government plans to increase undergraduate enrolments. He told CVCP there was no doubt that the proportion of students qualified to enter higher education would continue to rise, and expressed delight that universities were responding to the increase in demand "spurred on" by the "incentive" of receiving higher fees from October 1990.

An increase of 6,000 extra students has been reported for entry next year. Moreover, the government has revised upwards its estimate of the Age Participation Index (API, the proportion of individuals aged 18 and 19 going into higher education) which in 1989 stood at 15 per cent: the forecast API for the year 2000 has risen from 18.5 per cent to 23 per cent.

The CVCP welcomed the plans to increase university numbers but in a statement said "it becomes clear the government will not pay for the expansion it desires at a level which will protect high quality". Sir Edward Parkes, chairman of CVCP, foresaw three options by which the increase could be financed: universities could charge fees, a graduation tax related to income could be introduced or the high standards of higher education could be allowed to decline. He suggested that universities could charge full-cost fees, which most undergraduates would be able to meet largely by scholarships derived from government funds.

Such a scheme would enable universities to select potential students from lower economic classes. Universities could play Robin Hood, he argued, by "squeezing the middle classes and employers to pay for the less affluent". Students from lower economic groups would be awarded scholarships based on merit, whereas wealthier students would pay full tuition fees. Universities would publicize the full costs of each course. These would be above those charged to overseas students, which range from £4,000 a year for an arts course to £10,000 for medicine. Parkes emphasized, however, that this system was not a CVCP policy initiative but an avenue to explore.

The CVCP would appeal to present and prospective students, parents and employees for help in persuading the government to provide generous scholarship support. These actions constitute a genuine way forward, Parkes declared, and should not be thought of as alarmist tactics to force the Treasury to give more money to higher education. The vice-chancellors, he concluded, "are not playing games".

The Association of University Teachers (AUT), condemnded the CVCP's proposals because they would restrict higher education to the 'privileged few'. Diana Warwick, AUT general secretary, said the CVCP had invited the government to privatize universities and "turn them into yuppy finishing schools". **Ben Webb**

PLAGIARISM

Justice not seen to be done?

Washington

A VISION researcher charged by the National Institutes of Health (NIH) with scientific plagiarism, and facing debarment from all federal funds is, not surprisingly, attempting to fight the decision. But he claims that, having been given no real chance to defend himself early on in the proceedings, he may now be the victim of a cursory justice against which he has no legal right of redress.

Two months ago, an NIH investigatory panel declared that C. David Bridges, a vision researcher now at Purdue University, had plagiarized material from a paper sent to him for review, and then published it as his own, in the journal *Science* (see *Nature* **340,** 173; 1989). NIH terminated Bridges' current grants and excluded him from service on any peer-review or advisory bodies, actions which the then director of NIH, James B. Wyngaarden, could take by endorsing the panel's recommendations with his signature. But the panel also recommended that Bridges be debarred from receiving federal funds from any source. This NIH have not the power to do, and the recommendation was passed to the Deputy Assistant Secretary for Procurement Assistance and Logistics in the Department of Health and Human Services, who was also to determine the period of debarment. On 18 August, Bridges received a letter from James F. Trickett, DHHS Deputy Assistant Secretary for Management and Acquisition, notifying him that debarment for a period of five years was being considered, and giving him 30 days to respond.

Bridges claims that Trickett's letter give him "no clear idea" of what the next step in the process might be. But Les Ribnik, clerk to George M. Bishop, Bridges' lawyer, said that the letter included copies of the appropriate sections of the Code of Federal Regulations, according to which the debarment procedure is conducted. On 13 September, Bishop wrote to Trickett with a lengthy and detailed response to the charges made by the NIH panel, and requesting a "trial type hearing".

Whatever the next step may be, it will probably take most of the participants into uncharted waters. A "trial type hearing", in which the two sides would be able to cross-examine each other, is not the kind of appeal hearing that would normally be given in such a case. Because there is no constitutional or other elementary legal right to receive federal research funds, suspension of an NIH grant, for example, comes under the jurisdiction of administrative law, not civil law, and a debarment hearing would be conducted somewhat in the manner of a civil hearing in some European countries, in which a presiding judge asks all the questions and the lawyers for each side are relatively quiet.

But Bridges' complaint is that he has not so far had any opportunity to question the evidence supplied against him, and will not get an opportunity if administrative law takes its course. Indeed, he believes it is entirely within Trickett's discretion whether to grant a hearing on the debarment or not.

Bridges sees himself so far as the victim of dealings that, although entirely legal, are of questionable virtue. When the NIH panel met for two days in Chicago to interview many of the protagonists in the case, Bridges and his lawyer were prevented, despite repeated requests, from having a transcript of the proceedings made, even at their own expense. A preliminary report by the panel was given to Bridges for his response, but nevertheless, he says, he still does not know on what or whose testimony some of the charges were based.

Much of Bridges' rebuttal of the charges against him is an amplified version of his criticisms of the preliminary NIH report which, he says, were not satisfactorily answered in the panel's final version. The NIH review concluded that Bridges could not, as he maintains, have done the crucial experiments before he received a paper from Robert Rando *et al.* for review, because he did not until later acquire sufficient supplies of a tritium-containing reagent, with a restricted shelf-life, essential for the work. Bridges' response sets up a history by which, if earlier supplies of the tritiated reagent were carefully husbanded, and smaller quantities used than Bridges' former technician told the panel, some experiments could have been done before fresh supplies were ordered.

The NIH panel also argues that Bridges suddenly started using the experimental conditions and reagent mixes specified by Rando *et al.*, without any precedent in his earlier laboratory work. Bridges' response is to pick out elements of his previous experiments and draw a thread of reasoning which pulls them together in the later, disputed work.

Bridges maintains that had he been able to make this case to the review panel earlier, and to see and criticize the evidence laid against him, the whole affair would not have got this far. And although he has now assembled an argument which he says would dispel the charge of plagiarism, he fears he will not get the chance to present it. But Trickett, the DHHS official from whom Bridges is waiting to hear, says the right to appeal is one he "insists on", and promises that if Bridges has a case it will be heard. **David Lindley**

MOLECULAR BIOLOGY

Squibb builds new laboratory

Paris

THE Squibb Corporation, the US pharmaceutical company, is to spend more than FF280 million ($43 million) on a basic research initiative in molecular biology at the Université Louis Pasteur in Strasbourg, on the Franco-German border. The deal includes construction of a FF154-million laboratory and support for about 50 scientists for the next seven years. In return, the company will have the right to claim up to half of the projects carried out within the laboratory as theirs, with the option of an exclusive world licence should patentable results emerge.

The 10,000 square metre building should be completed in 1992, on a site in Strasbourg's suburban science park. Under the arrangement with Squibb, if the present 12-year contract is not renewed, the laboratory will remain at the disposal of researchers and after 50 years will revert to the university.

At present, the university's molecular biology laboratory has about 160 staff, mostly employed on permanent contracts by either the state medical research organization, INSERM, or the national science research centre (CNRS). This, says Pierre Chambon, who will direct the new laboratory, means that it is difficult to have a turnover of young researchers. Now, with running costs of around FF18 million per year provided by Squibb for the first seven years, some twenty-five young scientists will be recruited on five-year contracts. To allow this arrangement to work, Squibb has agreed to renew its funding in five-year cycles.

Under the agreement, researchers will remain free to choose their research themes, without interference from Squibb. The work is likely to prove productive for the drugs company, however, as Chambon explains: "the kind of basic research we do, for example on regulatory proteins, will be useful for the design of new drugs over the next 10 to 15 years". The arrangement also does not preclude other companies from taking out licences on results in which Squibb has no interest. Chambon is confident that publication of important results will not be affected by the deal, with a maximum delay of around 45 days in the case of a patent application. Where a licence is taken out, Squibb will pay royalties to CNRS and INSERM.

In recent years, there have been several other examples of pharmaceutical giants, such as Hoechst and Bristol-Myers (now merged with Squibb), investing in basic research. And last July, construction began on a $32-million neuroscience research laboratory at the University of Oxford under a similar 12-year arrangement with Squibb.

Peter Coles

HYDROELECTRICITY

Danube neighbours' travails

London

THE long-standing dispute between Hungary and Czechoslovakia over the Gabcikovo–Nagymaros hydroelectric scheme has taken a new turn. Angry at the continuation of the Hungarian moratorium on construction, the Czechoslovak engineers are drawing up contingency plans for "technological countermeasures". These, the Hungarians fear, would pose a far greater ecological threat to northern Hungary than even the original plans.

Last May, in response to growing pressure from 'green' groups in Hungary, the Hungarian government declared a moratorium on its side of the joint project, pending yet another expert survey. Czechoslovakia immediately countered with claims for compensation, saying that without the planned dam downstream at Nagymaros in Hungary to catch its tail-waters, the Gabcikovo station in Slovakia could never operate at full power. The Hungarians denied these claims; whereupon the Czechoslovak commissioners switched their attention to Hungary's upstream part of the project — the damming of the river-bed at Dunakiliti (where the Danube flows between Hungary and Slovakia), to divert the river into the new Hrusov reservoir which will supply the Gabcikovo station.

If this reservoir is to be filled by the deadline of December 1990, then the Dunakiliti diversion would have to be completed this October when the hydrological conditions are at their most favourable, with an average flow of about 1,500 cubic metres per second. Once the autumn floodwaters start to rise, the final stage of the diversion operation will have to be postponed, perhaps for a full year, and if the flow exceeds 2,000 cubic metres per second, it may become necessary to destroy the partly finished constructions in order to avoid flooding. Such a postponement, according to Jozef Oblozinski, one of the Czechoslovak government commissioners for the project, could have "catastrophic consequences". Already the Gabcikovo section filling with groundwater, he told the Bratislava daily *Pravda* and if this is not balanced by Danube water entering from above, the foundations of the dam might start to shift.

The projected Czechoslovak "countermeasures" would mean moving the planned diversion to Somorja, some 14 km upstream, where both banks of the Danube lie in Slovak territory. If the Czechoslovak official pronouncements are taken at face value, work will begin on the new diversion "if the two governments fail to agree by October". No agreement has, in fact, been reached, but the Hungarians hope that the announced plans were intended more to strengthen the Czechoslovak bargaining position than as a real commitment. The proposed new diversion, says Laszlo Udvari, the chief Hungarian commissioner for the dam, would have a major impact on the water table in north-west Hungary and would, moreover, have an adverse effect on shipping conditions. Since the Danube is an international river, he says, Czechoslovak "countermeasures" would raise the controversy from a bilateral one to a matter affecting "all those states involved in Danube shipping, and, indeed, all those who have an interest who have an interest in the politics of Europe". The Hungarian government, Udvari says, still hopes to solve the dispute by "calm consistent negotiations".

So far, however, there seems little likelihood of such an agreement. Czechoslovakia desperately needs the extra energy the Gabcikovo dam will produce, particularly as its electricity imports from the Soviet Union have been cut for three successive months, and further cuts are expected this winter. The Hungarian government, however, is now committed to go ahead — if at all — only on the basis of a further expert survey and the consensus of public opinion. Even if the Hungarians do, eventually, decide to complete their part of the project, they are not likely to be hurried into meeting the Czechoslovak deadlines. **Vera Rich**

MOTIVE POWER

Powered by hydrogen

Washington

THE hydrogen-powered car pictured here hesitated a little before starting on an unexpectedly cold Washington morning, but then successfully carried Senator Tim Wirth (Democrat, Colorado) and Representative Claudine Schneider (Republican, Rhode Island) on a 50-yard trip in front of the Capitol building. The modified Mercedes car, a research vehicle built by Daimler-Benz in West Germany, was brought over to mark the release of a study commissioned by the Washington-based World Resources Institute that argues for hydrogen, generated by solar electricity, as the environmentally benign transportation fuel of the future.

By burning hydrogen in a fairly conventional engine, the car emits no carbon dioxide or sulphur dioxides, although it inevitably produces some nitrogen oxides from reactions with nitrogen in the air. But if the hydrogen fuel is made by electrolysing water, using electricity generated by coal or oil, the indirect consequences for the greenhouse effect and for acid rain are as bad as if the car used gasoline. The argument set out in the new report* is that recent efficiency improvements and cost reductions in photovoltaic devices can make electrolysis of hydrogen by solar-powered devices as cost-effective as other suggested petroleum fuel replacements, such as methanol or ethanol.

The prototype car stores enough hydrogen, in a rechargeable metal hydride absorption device, to take it only about 75 miles.

Basing its calculations on a lighter, more fuel-efficient vehicle, the study estimates that about 280 square feet of solar collecting area would be needed to make the fuel for a car that was driven 10,000 miles in a year. This translates into half a per cent of the entire land area of the United States (or one-sixth of New Mexico) to provide for every car in the country.

Wirth and Schneider, after their short trip, praised the West German government for its support of the development work by Daimler-Benz, and castigated US government and industry for their lack of such research. The sudden drop in crude oil prices of a few years ago was accompanied by a similarly precipitous loss of official interest in energy conservation programmes and alternative energy sources, but alarm over global pollution and warming has begun to revive old concerns. **David Lindley**

* *Solar hydrogen: moving beyond fossil fuels* by Joan M. Ogden and Robert H. Williams. World Resources Institute 1989.

The modified Mercedes 230E will reach a speed of 105 mph — but has a driving range of only about 75 miles.

SOVIET PSYCHIATRY

IPA claims harrassment

London

THE Soviet Union's new Independent Psychiatrists' Association (IPA) has appealed to psychiatric associations abroad for support following a burglary which it is convinced was deliberate harassment by the Soviet security police. The IPA was founded earlier this year. Its members, from all parts of the Soviet Union, consider that, the Soviet psychiatric establishment is still dominated by those who, during the Brezhnev era, made Soviet psychiatry a byword for political repression and abuse of human rights.

IPA maintains that, in spite of public denials and the visit to Soviet mental hospitals of a "verification" team from the United States, persons of sound mind but inconvenient views are still being committed to Soviet psychiatric hospitals.During the past few months, they have been compiling an archive of known cases as well as offering professional help to patients who, for various reasons, do not wish to seek help through the state system.

Their records, together with correspondence with psychiatrists abroad, were housed in the apartment of one of the association members. A few weeks ago, when the householder was absent for only two hours, the apartment was broken into and the files removed. The break-in, says the IPA, was obviously not the work of an ordinary burglar, since valuables were left untouched.

In an open letter addressed to psychiatric associations throughout the world, Aleksandr Ogorodnikov, a human rights activist and founder-member of the IPA, says that harassment of this kind will not deter IPA, but its members are afraid that seizure of the archives could bring harm to those who have asked IPA for help.

The position of the IPA, Ogorodnikov wrote, would be considerably strengthened if it could become a member of the World Psychiatric Association. Shortly after its foundation, IPA submitted an application for membership, to be considered at the next General Assembly of the WPA, in Athens next week. But the WPA secretariat has refused to process this application, on the grounds that it should have been submitted a full year in advance, when IPA did not exist.

The WPA executive shows signs of proving far less rule-bound in the case of the official Soviet psychiatric society. That organization resigned from the WPA in 1983 to forestall several motions on the agenda for its expulsion. The establishment psychiatrists will also be seeking readmission to the WPA next week although in its present form that body, too, has existed for less than a year. **Vera Rich**

IAEA CONFERENCE

Soviets take French lesson

Vienna

SPEAKING candidly at the 33rd general conference of the International Atomic Energy Agency (IAEA) last week in Vienna, Soviet representatives admitted that the Soviet Union faces serious problems in the continued expansion of its nuclear programme. But, while also announcing a strong commitment to protecting the environment, the Soviet government intends to persist with plans for more nuclear power.

The problem is familiar to Western planners: the Soviet Union would like to increase its power generation capacity by building both nuclear and non-nuclear plants. But nuclear plants run into public opposition, while clean-burning fossil fuel plants are expensive.

With the Chernobyl accident still fresh in the memory, no new Chernobyl-type reactors will be built. Nevertheless, according to Chairman A. N. Protsenko of the State Commitee on the Utilization of Atomic Energy, nuclear generating capacity will be doubled by the year 2000, increasing the proportion of Soviet electricity derived from nuclear power from 13 to 15 or 16 per cent.

But "public opinion affects the rate of construction," he said. Protsenko admitted that, while other countries had carried out effective public relations campaigns to make people aware of safety measures at nuclear power plants, "we did not". He attributes what he sees as a "negative attitude" towards nuclear power in the Soviet Union to a "lack of awareness", and revealed that the Soviet Union had been taking lessons from France in how to convince people that nuclear power is safe. A Soviet team visited France one month ago to observe French public relations efforts, and made films for Soviet television.

Slower growth in nuclear capacity has led to plans for more fossil fuel power stations, but the cost penalty of 60 to 70 per cent incurred by equipping a coal-fired power station with scrubbers to remove sulphur and other pollutants has persuaded the Soviet Union to construct its new - and unclean — plants in sparsely populated regions such as the Ural Mountains. This is a "temporary measure," Protsenko added.

Environmentalism has apparently seeped into official Soviet thinking: Protsenko cited a figure of 50,000 million rubles per year ($79,400 million at the official exchange rate) for the total cost of damage due to environmental pollution in the Soviet Union. One quarter of this is attributed to power generation. Protsenko expects the Supreme Soviet to devote more money to the environment in the 1990 budget. When asked if this would not be difficult in light of the country's problems in providing items such as basic foodstuffs for its population, he said that it was equally important to provide "foodstuffs and clean air". But Soviet delay in cleaning up the air was criticized by other countries. Rolf Annerberg of the Swedish Ministry of Environment and Energy said that transboundary pollution contributes 75 per cent of the air pollution in Sweden, and called on the Soviets to improve the efficiency of their existing plants instead of building new ones. But Annerberg welcomed the Soviet willingness to discuss the issue. "Before, it was impossible to have anyone say there was a problem", he said.

A number of other Soviet announcements at the conference met with the same mixture of pleasure and scepticism. The Soviet offer to site an international research centre on the consequences of nuclear accidents and nuclear accident management at Chernobyl was repeated. The idea had originally been mentioned to the IAEA board of governors in June.

In a closed meeting, representatives of the IAEA member states that have nuclear power showed some interest in the proposal, although they raised a number of questions that the Soviets chose not to answer. For instance, they asked what research the Soviets had already done at Chernobyl and what purpose an IAEA-sponsored agreement would serve in gaining international access to the site. Although no public response was given, the Soviets were thought to have offered to share results from their investigations and access to waste materials from both the 1986 Chernobyl accident and the 1957 nuclear explosion at Kasli in the Urals (see *Nature* **339**, 572; 1989).

The Soviet offer will now be considered by member states before any official response is made. The issue is set to be discussed again at the February board of governors meeting.

IAEA director general Hans Blix of Sweden, whose election to a third four-year term was confirmed by the conference, said that the Soviet Union had also offered to provide a site for an international research project in waste disposal, possibly in the Chernobyl area. But Soviet representatives did not elaborate.

Long-running IAEA issues such as South African and Israeli nuclear capabilities took second place at this year's conference.

South Africa once again promised to consider signing the nuclear non-proliferation treaty (NPT), and will meet with the United States, the Soviet Union and the United Kingdom in December to discuss the matter. The conference postponed for another year a resolution to bar South Africa from the IAEA.

Steven Dickman

Sex statistics unreliable

SIR—Whether or not the British government is right to cancel a proposed social survey of contemporary sexual behaviour, intended to help understand the mechanism of the spread of AIDS, as being "too intrusive" to be supported with public funds, at an estimated cost of £750,000, is perhaps arguable (*Nature* **341**, 87; 1989). It would certainly give rise to much salacious comment in the news media, although that would not necessarily have done much harm.

But the real argument against this survey is that its results were bound to have been unreliable. First, although a random sample of people would have been invited to participate, anyone would be free to refuse, so the respondents would be self-selected and probably not representative of the population as a whole. And second, "the questionnaire would have been self-completed in the argot of the social science trade: respondents would have completed the questionnaire themselves, sealing it into an envelope provided, referring to the survey official delivering the questionnaire only in case of ambiguity".

As this questionnaire, devised by "a large group of British AIDS researchers", is likely to have been long and complicated and rather technical in parts, it would not have been easily understood by many of those asked to complete it by themselves. Nor can it be assumed that they would always be willing to discuss some of the embarrassing points they did not understand with the survey official. So, quite apart from deliberately false or frivolous answers, a good many of the questions would probably be misunderstood and answered incorrectly, and there would be no possible way of estimating how many of these there were.

The same problems arose with a long and complicated anonymous questionnaire distributed in 1966, designed to produce statistics relevant to the reform of the abortion laws, with demonstrably dubious results (C. B. Goodhart, *Population Studies* **27**, 207; 1973).

When trying to decide what should be done, it is a fallacy to suppose that it is better to have bad statistics than no statistics at all.

Permian of Spiti

SIR—I read with interest the article by A. D. Ahluwalia (*Nature* **341**, 13; 1989) under the heading 'Upper Palaeozic of Lahul– Spiti', having just spent 20 days doing fieldwork near Losar in the Upper Spiti Valley. Ahluwalia's observations are not correct and are not based on the section exposed in the Savita Nallah. I have worked in the section for the past two years and have made a systematic collection of rocks exposed in the area. Contrary to Ahluwalia's observation, a complete succession of Ganmachidam section is exposed in the Savita Nallah and has yielded fossils from different strata. The fauna collected from this formation range in age from Middle Carboniferous to Middle Permian. A systematic study of fauna collected from the section is in progress and will be published shortly. The Ganmachidam Formation in this section is overlain by black carbonaceous shales that are rich in fossils and have yielded well-preserved brachiopod fauna including *Lamnimargus himalayensis, Spiriferella rajah*. This fauna corresponds to the *Lamnimargus himalayensis* zone widespread throughout the entire stretch of the Himalayas and considered to be of Punjabian age.

Working in Japan

SIR—Although I have yet to visit Japan, I have taught myself rudimentary Nihongo and the most elementary reading and writing in *Kana* (the syllabic 'shorthand' Japanese characters) and *Kanji* (the Chinese characters). Thus I feel emboldened to comment on Shahid S. Siddiqui's question, "Under these attractive conditions, what prevents young US and (*sic*) other European researchers from coming to Japan?" (*Nature* **340**, 337; 1989). In answer, Siddiqui mentions most briefly "cultural differences" and "language".

The Japanese spoken language is admittedly very different from Romance and Teutonic tongues, both in structure and nuance. The written language, however, is virtually incomprehensible without arduous study (as is Chinese). This is the single biggest barrier in the long run.

To visit a foreign country has many benefits, but it can also be a formidable source of anxiety. Very few Americans (or other Westerners) can speak, let alone read or write, Japanese. Thus to live and work in Japan must appear to prospective visitors as virtually impossible.

Few Westerners know that most educated Japanese speak English fairly well (pronunciation excepted). Thus they see themselves faced with an unintelligible tongue in a land where both spoken English, and all the signage are equally unintelligible. It is a far cry from visiting Britain or the Commonwealth, or even the Netherlands or Scandinavia. Most educated Westerners know enough of other alphabets to cope in Eastern Europe. The Arab countries and Israel, with their seemingly undecipherable alphabets, have considerable English signage, but at least the characters *are* an alphabet. Consider then the situation for foreigners in Japan where the *Kana* (46 each of two types) represent syllables, not letters, and the *Kanji* (all 1,940 of them) represent complete words.

So, I humbly suggest that Siddiqui misses the main point of his question almost totally. The only steps that could easily be taken on a short-term basis would be crash courses in *Nihongo* in our institutions of higher learning and a change to bilingual Japanese and English signs in public places. The Japanese might also consider their signage in terms of broad use of *Romaji* (Japanese terms in Roman letters) to help accommodate visitors.

In my perhaps limited experience, the cultural differences between the West and Japan are insignificant compared to the language problem.

S. BERLINER III

Heat Systems Incorporated, 1938 New Highway, Farmingdale, New York 11735, USA

SIR—Several errors crept into the article "Basic research comes alive in Japan" (*Nature* **340**, 339; 1989). The KEK laboratory is in Tsukuba; the Ministry of Education, Science and Culture is Monbusho; the new Institute of Advanced Study is being launched by Kyoto and Osaka; and Riken is more naturally not completely capitalized, as it is the common abbreviation of Rikagaku Kenkyujo — the Institute of Physical and Chemical Research — and not an acronym. These small mistakes do aptly illustrate one of the points in the preceding article ("Too few foreign scientists in Japan" *Nature* **340**, 337; 1989) — language is indeed one of the problems facing foreign researchers in Japan. However, the English ability of most Japanese scientists and the assistance offered by many fellowships ensure that the problem should not be so large as to discourage those interested in working in Japan.

Chapter and verse

SIR—Your reports on recent patents for invention of exceptional importance, and on actions before the British and US courts are extremely useful, but not one of them gives the all-important number of the patent under discussion. Consequently each report necessitates an often lengthy search before the actual patent specification can be studied.

All patent specifications can be found by their distinctive number and thereby easily isolated from the 30 million patent specifications held at the Science Reference Library in London. The search for US patents is made more difficult if the report fails to give not only the number but the full names of the inventors, as the *US Patent Gazette*, issued weekly, does not give the names of the assignees.

I give below, for the benefit of your readers, the numbers of the important patents to which your recent reports have referred:

(1) "The shadow over immunoassay", (*Nature* **340**, 256; 1989) refers to US Patent 4376110, in the names of Gary S. David and Howard E. Greene.

(2) "The settlement on AIDS" (**326**, 533; 1987) embraces US Patent 4520113 to Robert C. Gallo *et al.* of 1985 (not 1984).

(3) The AIDS envelope protein patent (**331**, 649; 1988) is US 4725669 to Myron Essex and Tun-Hou Lee. There is a corresponding European patent application 201588.

(4) The first-ever animal patent issued in the United States (**332**, 668; 1988 & **338**, 366; 1989) is 4736866 to Philip Leder and Timothy Stewart. The corresponding European patent application is 169672. Each refers to *Nature* **294**, 92–94 (1981) as pertinent prior art, namely the article by F. Costantine and E. Lacy "Introduction of a rabbit β globin gene into the mouse germ line". US Patent Classification List Class 800-1 records about 50 earlier US patents, all directed to multicellular living organisms and unmodified parts thereof.

(5) The first US patent on tPA for Oxford University (**333**, 383; 1988) is 4751084 to Joseph Feder, William R. Tolbert, Thomas W. Rademacher, Raj B. Parekh and Raymond A. Dwek. The corresponding European patent application is 236289. The Genentech British patent application declared invalid (see Report of Patent Cases 1987 (24) p.553–589) is 2119804 and the corresponding US patent 4766075.

(6) The US patent involving T7 DNA polymerase-based sequencing technology developed at Harvard by inventors Stanley Tabor and Charles C. Richardson (**340**, 418; 1989) is US 4795699.

(7) The first US patent for superconductors, to Vander Sande and Gregory J. Yurek (**336**, 607; 1988) is US 4826808. (It was not reported in the *US Patent Gazette* until 2 May 1989, thereby requiring some 23 weeks of search.)

(8) The US patent for Montagnier, directed to HIV-2 (**340**, 253; 1989) is US 4839288.

Missing formula

SIR—V. A. Huszagh and J.P. Infante's Commentary (*Nature* **338**, 109; 1989) refers to one of the basic problems that inhibit the growth of knowledge in biological sciences: the uncritical accumulation of vast amounts of unconnected data arising from experiments that do not depend on any clearly formulated hypothesis.

Although the authors deserve merit for defining the problem, they do not go far enough in seeking an answer. The examples cited clearly indicate that theoretical solutions in biology are possible only if mathematical methods of another, more basic science fit the problem. Thus, in contrast to physics or even chemistry, biology by itself may be called an incomplete, that is exclusively experimental, science.

Until now, no serious attempts have been made to adapt mathematical logic to biology. Biology therefore lacks both exact principles such as axioms as well as a strictly logical superstructure.

Biologists see the complexity of biology as the only major hindering factor that prevents mathematics from becoming its appropriate theoretical frame. But this impediment might be overcome if there were not a second factor: the participating scientists themselves. Apparently, most of them look upon mathematics as a subject of philosophy — and philosophy is not in their sphere of interest.

What's in a name?

SIR—Your recent suggestion (*Nature* **341**, 89; 1989) that every member state of the European Communities should have two currencies, its own and the ECU, makes good sense, but it needs one important amendment. Governments for centuries have understood the need to associate bold images with their monetary units. And what image does the ECU suggest? An infinity of small grey men in small cubicles inhabiting the largest grey building in the world.

But what if we name our unit the Einstein? Or, since shortening and initialization is the order of the day, how about 1 Sks for Shakespeare, or 1 Rem for Rembrandt, or 1 Ps for Pasteur, or 1 V for Verdi, or 1 Ri for Riemann?

One could believe that a decision over which particular name to choose would cause great argument, sufficient to disrupt more than one European summit. But the need also to name the various multiples of the primary unit would accommodate quite a few great names. And for the primary unit itself there is one special name that might well recommend itself to everybody, partly from a sense of irony and partly as a much-needed retribution. So let the primary unit be named after someone whom the world of his own day buried in a pauper's grave. Let it be 1 Mz for Mozart.

A sensibly named currency would of course soon drive out national currencies on a European scale. But would it not also drive out other currencies worldwide? For who would want to carry dull dollars in their wallets when they could be carrying Mozarts? I ask you.

SIR—In your leading article entitled "Funny money" (*Nature* **340**, 580; 1989) you did not address the matter of its physical form. I suggest that consideration be given to replacing paper money by plastic or plasticized paper, of a size and shape like those of credit cards but thinner.

Cards should be washable, of standard weight and colour-coded. (Perhaps US notes are the only ones that still lack this feature.) They could have various metal strips to make them easily acceptable, distinguishable, sortable and countable in machines (for parking meters, telephone boxes, bus/train tickets, change, and so on). Suitably disposed fenestrae or notches could help the blind as well as the machines. Incorporation of specific diatom shells could add an unforgeable forensic feature, as could fluorescent threads.

Denominations could be variously printed for different countries (for example, red: 1 Eurobuck=DM2=FFr2=1,000 IL) on one side; on the reverse, the international value would be indicated in Esperanto. There would be no religious symbols or slogans in any text. If and when necessary, changes could be embossed.

Paper money is dirty and ephemeral; it is time we evolved better things.

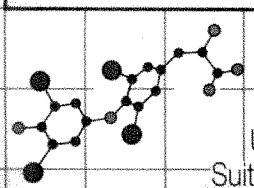
DESIGNER POLYMER?

Chem-X Can!

Chemical Design, the world's leading supplier of molecular modelling software, is pleased to announce a new Chem-X module aimed at polymer research. Exploiting Chem-X's open architecture, the ChemPolymer toolkit integrates specialist polymer building and property calculation functionality with Chem-X's powerful interactive analysis and display facilities.

Advanced building techniques allow ChemPolymer not only to generate regular, blocked and random homo- and copolymers from monomers, but also to handle branching to form network, ladder and star polymers. Polymer chains may be packed to form crystalline domains, using energy minimisation and a systematic search of inter-chain distances. Innovative functionality aimed at amorphous polymers is also offered.



Using statistical thermodynamics, the temperature dependence of properties such as entropies and free energies can be calculated for single chains.

ChemPolymer may also be used to evaluate many other characteristics of interest to polymer scientists, including free volume, stiffness, elasticity and geometrical variables.

Correlations between structural parameters and observed properties may be studied using existing Chem-X facilities which are fully integrated with ChemPolymer.

With over six years experience in developing molecular modelling systems, and three times more installations than any competitor, Chemical Design has the solutions to meet real user requirements. Whether you're interested in small molecules, proteins, polymers or inorganic materials, we can design a system to suit you.

Call us now for further information or to discuss your modelling requirements — we'd be happy to hear from you.

Model lung breathes true

An interesting calculation of how the human lung functions has appeared in an Italian journal whose fortunes appear (from inspection) to be reviving.

ONCE upon a time, in the 1950s, *Il Nuovo Cimento* shared with the Japanese journal *Progress in Theoretical Physics* the distinction of being among the most eagerly read in its field, but it was then eclipsed by the emergence of rapid-publication journals such as *Physical Review Letters* and, later, of *Physics Letters*.

But *Il Nuovo Cimento* seems to be perking up. Nowadays, it is almost always possible to find something of interest in an issue. Part of the explanation is that, for the past eleven years, there have been four sections dealing separately with nuclear physics, astrophysics, condensed matter and general physics, which means that there are in principle four issues a month. In some sections, the publication lag (one of the reasons for the original decline) is still uncomfortably long — some papers seem to take a year in the process of publication But the more obscure backwaters of general relativity on which the journal retained a lien throughout its bleak period are no longer the staple diet for *Il Nuovo Cimento*'s faithful readers. Last month's condensed matter issue, for example, contains an intriguing calculation of gas transport in the human lung of a kind that would normally have been found in a physiological journal.

As F. Bonsignori and M. Salvini, both physicists from the University of Bologna, describe it, the problem is really fairly straightforward (*Il Nov. Cim.* **11D**, 1247; 1989). The trick, which has been used before, is to represent the lung and its airways, the trachea and bronchi, by a kind of one-dimensional model. They follow physiologists in supposing that there are 23 generations of successive refinement in the lung, at each of which the total area of the walls across which gas can be exchanged increases. The problem then becomes that of calculating the processes by which exchangable gases reach the walls of the lung and diffuse through them.

The physiological data used to ground the model are striking in themselves. The cross-section of the airways increases from 2.54 cm^2 in the trachea to 11,800 cm^2 at the finest and twenty-third subdivision of the alveoli, whose total volume is a third of the capacity of the lung as a whole (taken to be just over 1.5 litres, everything included). The most obvious consequence of this state of affairs is that gas velocities progressively decrease from the mouth to the alveoli, so that in the main airways into the lung, turbulent motion and convection are chiefly responsible for gas transport, but molecular diffusion dominates in the alveoli.

Bonsignori and Salvini acknowledge that their model is not original, but they do claim to have improved on earlier calculations (in the 1970s) by improving on some of the approximations on which previous calculations have been subject. For one thing, they reckon to have used a better representation of the cross section of the lung with distance along the airways. More pointedly, they allow for the way in which the effective diffusion constant can vary with the velocity of the flow and with place along the airways. In the alveoli proper, the implicit assumption is that the gases in the lung exchange their contents freely with the blood, which is for practical purposes regarded as an infinite reservoir.

The objective is to write down and then to solve a differential equation for the diffusion and convection of gases along the airways; Bonsignori and Salvini judiciously discuss the boundary conditions that should apply at the walls of the airways, acknowledging that in the alveoli, at least, there are grounds for believing that the concentration of one component of gas inspired will be virtually constant along directions perpendicular to the walls of the alveoli, and that from some point sufficiently deeply buried in the network, the concentration of all components will be virtually unchanging in space and time. But this implies that there are two formally different sets of boundary conditions that may be relevant, whence the suggestion (not further followed up) that some mixture of the two would be most appropriate.

The variations of the effective diffusion coefficient, which determines the effectiveness of mixing under different circumstances, are tackled semi-empirically. In the entering airways, mixing is much more efficient than would be determined by molecular diffusion, but in the alveoli, molecular diffusion is king. Part of the construction of the equations to be solved entails fixing parameters by reference to the known parameters of the lung, using the helpful (and reasonable) conditions that air should not accumulate anywhere in the system. The remarkable feature of the calculation is that it leads to an explicit result, although one in which several numerical approximations have been made.

The outcome of the calculation is much what physiologists would expect. The authors restrict themselves to the case in which it is supposed that somebody takes in a single substantial breath, holds it for a little while and then empties the lungs. What the solution of the equation shows is, first, that a component of the inspired gas progressively penetrates through the system with the passage of time, and that the process is the more rapid as the incoming flow is faster.

The supposition that, in the outer reaches of the system, the concentration of particular components of the inspired gas quickly become more or less constant readily falls out from the calculations, but concentrations in the inner reaches quickly fall to zero as gas is rapidly absorbed across the alveolar walls. The time constant of the system appears to be a few seconds — rather more than 4 seconds in one significant context — which accords with general experience of trying to hold one's breath. It may or may not be coincidence, but the calculations appear to show that, when breathing air, the model lung reaches in just over a second a condition in which the oxygen concentration is virtually constant throughout the inner part of the respiratory system, taken to be the last seven generations of airway refinement.

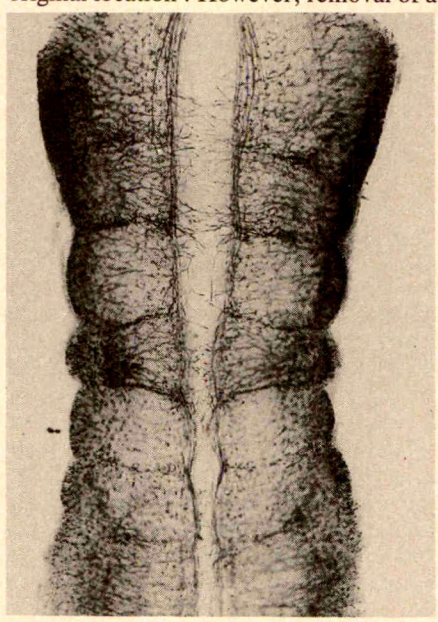
Inevitably, the authors promise to produce a second set of more refined calculations, paying particular attention to the vexed question of the boundary conditions most appropriate in different parts of the respiratory system. At this stage, however, nothing is said about the assumptions that the gas in the lungs is incompressible, or that there is no interference between the different components of the inspired gas that people breathe. No doubt the next step will be to collect some carefully controlled experimental data in the hope of matching calculation and experiment.

The interest of all this is not simply that it is what seems to be a reasonably realistic calculation of the properties of a complicated physiological system, but that it appears in a straightforward physics journal. No doubt the bibliographic retrievers will alert physiologists to what they may otherwise overlook, but that it should have appeared there at all is a neat sign of how broadly catholic is the Italian Physical Society.

John Maddox

VERTEBRATE DEVELOPMENT

Genes and segmentation



Julian Lewis

SIXTY-SIX years ago, in the early days of *Drosophila* genetics, the first of a strange class of mutations was described[1]. The mutant fly, called *bithorax*, had its third thoracic segment, which should normally carry a pair of balancers, partially converted into a duplicate of the second thoracic segment, which carries wings: the relationship between location in the body and selection of a developmental pathway had been upset. This was the beginning of a chain of discoveries that began slowly but is now taking us at a dizzying pace towards a revolution in our understanding of the mechanisms of development. Findings from *Drosophila* are illuminating the development of other animals too. From several recent papers, including one on page 405 of this issue[2], it appears that there are profound similarities between vertebrates and insects in the genesis of their body plan, in particular with respect to segmentation and the genes that give each body segment the character appropriate to its location.

Mutations that, like *bithorax*, cause segments of the body to develop as though misinformed about their location define a class of genes called homoeotic selector genes. As more such genes were discovered in *Drosophila*, it became apparent that many of them were grouped into one or other of two tight clusters in the genome, called the antennapedia complex (ANT-C) and the bithorax complex (BX-C). ANT-C contains genes specifying the differences between anterior segments, while BX-C is responsible for the pattern of differences between posterior segments. If, for example, the whole of BX-C is deleted, all segments posterior to the mid-thorax develop as duplicates of the mid-thoracic segment[3]. (For simplicity, I use the term 'segment' loosely; in the technical jargon, 'parasegments' would be the more exact term here.)

More detailed analysis of BX-C revealed a curious regularity. Mutations at different loci within the complex affect different domains of the body, and the order in which these loci are arranged within BX-C corresponds with the spatial ordering of the affected domains along the body axis[3]. In other words, as one passes to more posterior levels in the body, the genetic elements of BX-C are called into play sequentially according to their location in the chromosome. The same is true for ANT-C in *Drosophila*[4]. And in the beetle *Tribolium*, where a single giant complex combines the functions of ANT-C and BX-C, the correspondence between the genetic map and the body axis is preserved over its whole length[5]. Borrowing terminology coined for the beetle, it is convenient to call any cluster of homoeotic selector genes organized in this fashion a HOM complex and its members HOM genes[6].

HOM complexes have a further property that seems to be crucial for their function. Cells of each body region in *Drosophila* become stamped during development with a permanent record of their location along the head-to-tail axis. For example, when imaginal disks (the immature larval rudiments of adult structures) are transplanted, their cells persist in differentiating according to their original location[7]. However, removal of a

Rhombomeres in a chick embryo hindbrain (from ref. 21) — homology running deep?

HOM gene (by X-irradiation) from a small clone of cells within one imaginal disk late in the development of the animal can convert that group of cells to the character appropriate to another region[8]. This suggests that a cell's memory of its antero–posterior location in the embryo depends on maintenance of the extent of activation of its HOM complexes, which presumably must become frozen at the level to which they have been driven by some transient embryonic signal, graded along the body axis. (There are intriguing parallels here with the phenomena of X-inactivation and position-effect variegation[9], where again a change in gene expressibility spreads to a variable extent along the chromosome, becomes frozen at a critical time in development, and is thereafter remembered by the cell and its progeny.)

The meaning of the 'extent of activation' of a HOM complex has been clarified by molecular cloning of BX-C. This complex, though it governs the patterning of at least nine segments, comprises only three protein-coding genes, *Ubx*, *abdA* and *AbdB*. *In situ* hybridization shows that these genes are expressed serially along the body axis in accordance with their chromosomal locations[10]. However, the genes are not expressed uniformly in all the cells of a given segment; instead, the gene products are used in a more subtle and variegated way to give each segment a unique character. Each of the structural genes is regulated by a complicated entourage of enhancers, and its expression is differently modulated within each of the segments where it is required for normal development. Many of the homoeotic mutations disturb the enhancers rather than the structural genes, and the correspondence between chromosomal location and spatial domain in the body holds true in a more complete and detailed way for the regulatory loci than for the structural genes themselves. It seems the enhancers become 'open for business' — that is, receptive to *trans*-acting transcription factors — sequentially in successive segments according to their position in the chromosome, thereby exposing the associated structural gene to a particular segment-specific style of regulation[11].

It is not yet clear what drives the progressive opening-up of the HOM complexes along the body axis (though information that should lead to an answer is rapidly accumulating[12–14]); nor is it known how the stage of HOM activation attained during embryogenesis is preserved and inherited from parent cell to daughter cell thereafter. But whatever the molecular mechanisms may be, the properties of the HOM complex make it a very useful developmental gadget: the extent of its activation can represent for the cell a record of the magnitude of an influence to which it or its ancestor was exposed in the embryo. The 'magnitude' of the influence might mean its duration, or its intensity, or some product of the two: one could conceive of a HOM complex being used to record the value of almost any sort of graded developmental variable. Indeed, recent work suggests that in vertebrates HOM complexes are used in a variety of ways to specify the pattern of several different parts of the body — not only the axial structures but also the limbs[15,16].

HOM and *Hox*

It would not be possible to speak of HOM complexes in vertebrates had it not been for another discovery in *Drosophila*. All of the fly's HOM genes were found to include a sequence of 180 base pairs, the famous homoeobox, coding for a highly conserved DNA-binding protein domain. Evidently all these genes, both in BX-C and in ANT-C, have arisen by duplication and divergence from a common ancestral

homoeobox-containing gene, whose product presumably acted as a master-regulator of the activities of other genes. The discovery of the homoeobox made it possible to fish for homoeobox-containing genes elsewhere in the *Drosophila* genome and in the genomes of other animals.

In mammals and other vertebrates one finds, as in *Drosophila*, many genes that contain homoeoboxes, and among them a special subset that, by virtue of an astonishing set of parallels with the insect HOM genes, may also be called HOM genes. They are grouped into a small number of tightly linked clusters, or HOM complexes. In the mouse, at least four such complexes, called Hox-1, Hox-2, Hox-3 and Hox-5, have been discovered. The individual genes of a given HOM complex, as in *Drosophila*, are expressed in different regions along the head-to-tail axis of the body, the pattern being clearest in the central nervous system[17].

Moreover, several of the mammalian HOM genes can be identified as individually homologous to specific *Drosophila* HOM genes: thus *Hox-2.1* is a mouse homologue of *Drosophila Scr*, being more closely related to it than to its chromosomal neighbours, *Hox-2.2* and *Hox-2.6*. Similarly, *Hox-2.6* is a specific homologue of *Drosophila Dfd* — and so on. Again, a simple correlation is seen between the location of a gene within its complex on the chromosome and the region where it is expressed in the body of the animal: the further the gene lies from the beginning of the HOM complex, the more posterior the domain to which its expression is restricted[18,19].

The similarity of organization and the pattern of homology and divergence in the HOM complexes of insects and mammals suggest that their common ancestor already possessed a HOM complex containing counterparts of at least some of the insect HOM genes, and used this complex as insects (and probably we) do, to specify the differences between successive regions along the head-to-tail axis of the body. The homology of the HOM genes between insects and vertebrates suggests also a homology of body parts, defined according to the HOM genes they express. But the drawing of parallels between insects and vertebrates immediately raises problems, for at first sight their bodies seem to be constructed on radically different principles.

The insect body is built from segments — a series of modules that are repeated with variations along the anterior–posterior axis. Differences of HOM-gene expression specify the differences between the segments, and the boundaries of HOM-gene expression domains are exactly aligned with segmental (or parasegmental) boundaries, as a result of regulation of HOM-gene expression in the early embryo by the genes that generate the segments[13].

What then is the vertebrate counterpart of an insect segment? Are vertebrates segmented in the same sense in which an insect is segmented? Initial attempts to answer this question naturally enough focused on the segmentation that is most obvious in our own bodies, corresponding to the series of somites in the embryo or of vertebrae in the adult. But it has been persuasively argued[20] that this could not be homologous to the segmentation of the insect: the somitic segments of a vertebrate develop in a way that is completely different from the body segments of an insect and, according to most accounts, they must have evolved after the vertebrate and insect lineages diverged.

Rhombomeres

Several recent papers cast a new light on this problem and suggest that we have all been barking up the wrong tree: in the search for homology, we have to focus on another, and more ancient, system of segments in the vertebrate body. The expression domains of many of the mammalian HOM genes in the central nervous system have their anterior boundaries in the hindbrain. When examined at the appropriate stage of embryonic development, the hindbrain consists of a series of seven or eight bulges known as rhombomeres, delimited by slight constrictions (see figure). This obscure detail of embryonic anatomy took on a new significance when it was shown[21] (in the chick) that the bulges and constrictions reflect a regular repetitive segmental organization of the neurons and glia in the neural tube, correlated with the series of cranial motor-nerve roots and cranial sensory ganglia, and thereby correlated also with the series of branchial arches — or gill arches — that they innervate. *In situ* hybridization studies showed that rhombomeres are also delimited biochemically: the *Krox-20* gene is expressed in rhombomeres 3 and 5 (ref. 22), whereas the *int-2* proto-oncogene is expressed (transiently) in rhombomeres 5 and 6 (ref. 23).

The rhombomeres thus define a set of landmarks in the hindbrain that must have some major developmental significance. A recent paper in *Nature*[24], and another in this week's issue[2], now reveal that the rhombomere boundaries correlate precisely with the expression boundaries of HOM genes. For example, *Hox-2.9* is expressed in rhombomere 4, in a region delimited so sharply that one is reminded of the compartment boundaries seen in *Drosophila*. The other four genes of the Hox-2 complex that have been examined in this way (*Hox-2.1*, *-2.6*, *-2.7* and *-2.8*) are also expressed in domains, the anterior boundaries of which coincide with the boundaries of rhombomeres. What is more, for each step from one of these genes to the next along the chromosome, the anterior expression boundary jumps two rhombomeres closer towards the head, just as the anterior boundaries of the expression domains of successive *Drosophila* HOM genes are, for the most part, spaced at two-segment intervals[24].

Perhaps these parallels between the rhombomeres of the vertebrate and the segments of the insect are just a trick of convergent evolution — a case where two classes of organisms have independently evolved systems of segments, which would thus be analogous but not homologous, and independently coupled the activation of a HOM complex to the segmentation machinery with the same spacing of two segments per HOM gene. Alternatively, there may truly be a homology which runs deep.

Comparative anatomy and palaeontology suggest that the series of gills is a more ancient feature of the chordates than is the series of somites[25,26]. It has been conserved faithfully in vertebrate embryos, even though subsequently modified out of all recognition in the adult mammalian body, where it gives rise to much of the face and neck. This conservation of the system of embryonic gill rudiments was emphasized by the founding fathers of evolutionary theory as evidence for the common ancestry of vertebrates. It would be pleasing if the same structures were to serve in our own day as a key to the relationships between vertebrates and invertebrates, and as an exemplar of the universality of the mechanisms of animal development. □

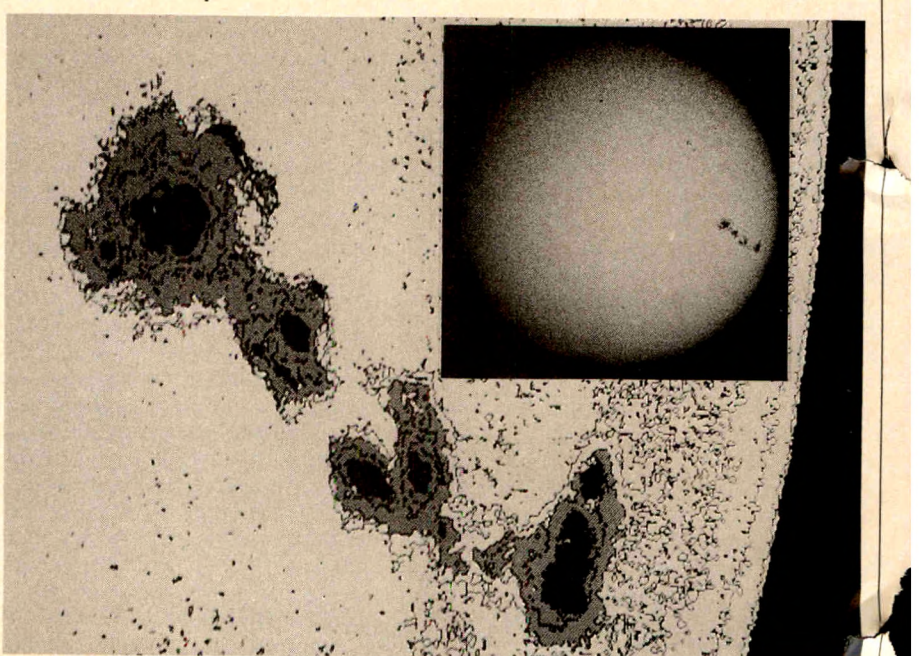
PROTEIN MODIFICATION

New clue to Ras lipid glue

Douglas R. Lowy and Berthe M. Willumsen

NORMAL Ras proteins encoded by the *ras* genes and oncogenic Ras proteins encoded by mutated *ras* genes (oncogenes) are synthesized as a precursor in the cell cytoplasm and then modified and translocated to the cytoplasmic face of the cell's outer membrane[1]. Localization to the membrane is critical for efficient Ras function, as the biological activity of those mutant Ras proteins that remain in the cytosol is severely impaired[2]. Until very recently, most investigators believed that it was the attachment of palmitate near the carboxy-terminus of Ras precursors that mediated their movement to the plasma membrane[3]. Now, evidence from three laboratories[4–6], each using a distinct approach and making a unique contribution, indicates that the lipid invariably added to mature Ras proteins is a farnesyl isoprenoid, and that palmitate is only an optional extra. The farnesyl moiety common to all mature Ras proteins is derived from farnesol, which is a branched-chain, polyunsaturated hydrocarbon alcohol intermediate of sterol biosynthesis. As farnesol is derived from mevalonate, pharmacologic agents which interfere with 3-hydroxy-3-methylglutaryl coenzyme A (HMG CoA) reductase (the enzyme that catalyses mevalonate synthesis), or other steps before farnesol synthesis, may be able to inhibit membrane localization of Ras protein, thus providing a potential approach to interfere with Ras-protein function.

The critical clues leading to these findings came from the recognition of the similarities between the post-translational modifications of fungal mating factors, such as yeast **a**-factor[3,7] and those of Ras. Indeed, a yeast mutant defective in post-translational modification of mating factor seems to cause a similar defect in yeast Ras[5,8]. The last four amino acids of both **a**-factor and Ras (see figure), when first translated, can be described as Cys–A–A–X, where Cys is cysteine, A is an aliphatic amino acid (most often the hydrophobic amino acids leucine, isoleucine or valine), and X is any amino acid[3]. The carboxy-terminus of the mating factor has been shown to undergo several post-translational changes, including proteolytic cleavage of the A–A–X, carboxymethylation of the (now carboxy-terminal) cysteine and its farnesylation via thioether linkage to its sulphur atom[7]. Virtually identical modifications of Ras have now been shown to occur[4–6,9,10]. Furthermore, a Cys–A–A–X box, when placed at the carboxy-terminus of a protein that does not normally have one, is sufficient to direct its binding to an isoprenoid (presumably a farnesyl moiety)[4].



Palmitate, which was formerly believed to be linked to the cysteine residue in the Cys–A–A–X box, has now been shown to be linked instead to cysteine residues located in the first few amino acids upstream from the box. Moreover, the palymitoylation somehow depends upon post-translational modification of the box[2,4]. Rather than representing an obligatory step in Ras-protein function, palmitoylation can now be viewed as a modification that may modulate the biological activity of a given Ras protein. Supporting this hypothesis, palmitoylated Ras proteins have been found to be more firmly anchored in the membrane than non-palmitoylated versions and to be more active in stringent bioassays[4]. Most eukaryotes, including mammals, contain multiple *ras* genes that encode proteins with considerable sequence divergence in the 20 amino acids immediately upstream from their Cys–A–A-X box[1]. This sequence divergence is associated with variation in the precise location and number of cysteine residues that can be Palmitoylated (see figure). As the biological activity of a Ras protein seems to vary with the amount of palmitate that is added, each Ras protein may have its own particular level of activity, presumably to allow distinct functional roles to be better served than they could be by a single Ras protein. In addition, the palmitate bound to Ras has a much higher turnover rate than does the protein itself, which raises the possibility that alterations in the turnover rate of bound palmitate could represent an additional level of regulation[11].

ras^H	G	P	G	(C)	M	S	(C)	K	C	V	L	S
ras^N	T	N	G	(C)	M	G	L	P	C	V	V	M
$ras^{K}A$	P	G	(C)	V	K	I	K	K	C	I	I	M
$ras^{K}B$	K	K	K	K	S	L	T	K	C	V	I	M

Carboxy-terminal 12 amino acids encoded by the three mammalian *ras* genes: the last four residues constitute the Cys–A–A–X box. The farnesylated cysteine residues in the Cys–A–A–X sequence are boxed; upstream cysteines, which may be palmitoylated, are circled. The two termini shown for ras^K are the result of alternative splicing of two exons (A and B).

Other genes have also been identified that encode proteins with a terminal Cys–A–A–X box, with or without upstream cysteines that may be palmitoylated. Many of these proteins bind guanine nucleotides, as does Ras, and have additional regions of sequence similarity to Ras. But others, such as the nuclear lamins or HMG1 reductase, are similar to Ras only by terminating in the Cys–A–A–X sequence. It seems likely that at least some of these proteins will also be farnesylated. They could represent some of the as yet unidentified proteins that have been shown to incorporate mevalonate[6,12], as farnesol is derived from mevalonate. As lamins are associated with

Giant sunspot clusters mark solar maximum

WITH only 3 months until the solar maximum, violent activity — flares and sunspots — at the Sun's surface is increasing. This massive cluster of sunspots, photographed recently by N.W. Scott, traversed the Sun's face in 10–12 days. (Note: binoculars and telescopes should not be used for direct viewing of the Sun.) □

nuclear membranes and HMG1 reductase with the endoplasmic reticulum, their isoprenoid binding[12] suggests that this modification facilitates general membrane association, with other factors determining the particular membrane to which the protein is bound.

The number of proteins that are modified in the same way as Ras may be even greater than expected because the presence of a Cys–A–A–X box may be too stringent a criterion for their identification. Whereas the cysteine is obligatory as the first amino acid of the box in Ras proteins, the second or third positions can be occupied by some non-aliphatic amino acids (lysine, threonine, tryptophan) without affecting the post-translational modification or biological activity of the proteins[1,2,9]. Thus, the Cys–A–A–X box may have more the character of a consensus sequence, which may be present in many proteins.

As mutant, highly transforming *ras* genes are found in many tumours, inhibition of Ras function would seem to be an eminently worthwhile goal. Whereas past studies have already implied that it might in theory be inhibited through preventing the post-translational modifications required for membrane binding, the connection between the sterol biosynthetic pathway and Ras processing means that such inhibition can be tested experimentally, using known inhibitors of the pathway. Indeed, two related inhibitors of mevalonate synthesis, compactin and mevinolin, have been shown to inhibit isoprenylation of Ras and to prevent its membrane association[4,5]. There are several reports that such inhibitors, when used at concentrations much higher than those required to inhibit most cholesterol synthesis[13], can inhibit cell growth *in vitro* and sometimes induce cytotoxicity. Under some growth conditions, rodent cells transformed by the T24 *ras* oncogene may be more susceptible than the parental cells to growth inhibition by mevinolin[14].

But several theoretical problems underlie the potential clinical application of this approach, which, to be successful, must inhibit tumour growth to a much greater extent than it interferes with normal cell physiology. Although the inhibition of sterol synthesis might, in theory, be overcome by providing exogenous cholesterol (and/or its derivatives), it is not easy to imagine how it could be at least relatively selective for transforming Ras proteins when normal Ras and perhaps numerous other proteins are farnesylated, presumably by the same enzymatic process. Therefore, despite the understandable excitement generated by contemplation of this approach, it still remains to be demonstrated whether inhibitors of mevalonate synthesis are of use in the treatment of tumours. □

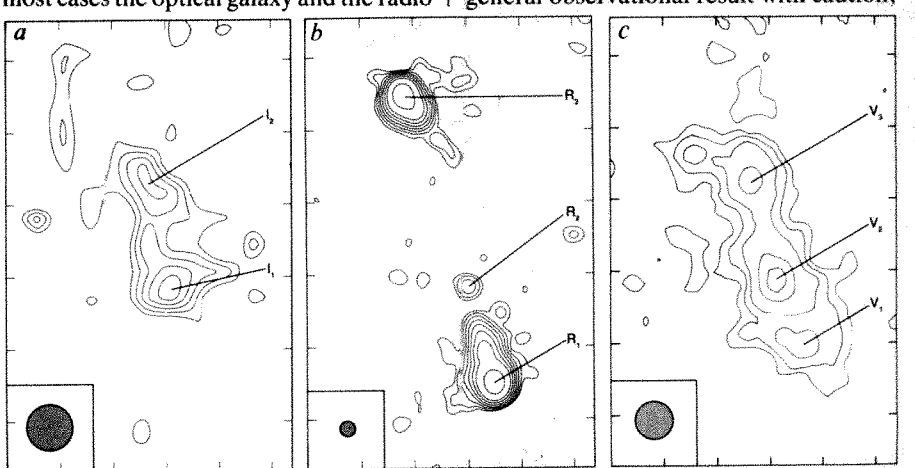
RADIO GALAXIES

Lining up the evidence



John Hutchings

THAT the radio images of radio galaxies and quasars seem to be very different from their optical images has long been a cause for debate. The general view is that the radio structure is determined by the energetic events occurring in the galactic nucleus which are largely unrelated to the distribution of the stars and dust that determines the optical structure. The typical bipolar form of the radio emission probably originates in the angular momentum of the central engine, and is probably aligned with the engine's spin axis. Naively, it used to be supposed that this axis, with little evidence, would be parallel to that of the visible galaxy, so that the disk or ellipse of stars should be perpendicular to the radio lobes. New evidence, however, seems to contradict this expectation, prompting Rees to propose a new model of the mechanisms involved[1].

The evidence comes from large new samples of galaxies that have been mapped with arcsecond resolution or better at both optical and radio wavelengths. Baum and Heckman[2] find in a sample of nearby (low-redshift) luminous radio sources that the 'orthogonal' rule applies only for radio structures that greatly exceed the host galaxy in size. In most cases the optical galaxy and the radio structure are disturbed and comparable in size. However, the authors also find that there is a strong correlation between the ionized gas (as distinct from the stars) in the galaxy and the radio structure, both in total power and spatial extent. They conclude that either the ionizing radiation emerging from the nucleus is collimated (or beamed) or the radio-emitting material itself is significantly disturbing the structure of the host galaxy. Independent detailed studies of several active galaxies have indicated that both phenomena occur fairly commonly.

At greater distances (higher redshifts), the situation is different. Beyond a redshift of 0.6, McCarthy *et al.*[3] and Stockton and Lilly[4] find an alignment of radio and optical structure. For redshifts over 1.0, the alignment becomes tighter (within 15°) and is more common, occurring in more than 85 per cent of cases (see figure). In addition, ionized gas can be seen at all places in — or beyond — the radio structure, even at hundreds of kiloparsecs outside the stellar boundaries of the host galaxy. These high-redshift galaxies are considerably more blue than their lower-redshift counterparts, and are considered to be undergoing very active star-formation.

It is worth approaching this apparently general observational result with caution,

The distant radiogalaxy 3C368, whose stellar and radio axes are aligned. These images are taken, *a* in the infrared K band (2.2–μm wavelength), *b*, at radio frequency (5 GHz) and *c*, in the visible (R+V+B bands). (From ref. 8; images *b* and *c* by Djorgovski *et al.*[9].)

however. First, as Stockton and Lilly point out, the concept of optical position angle is applied not only to truly elongated continuum sources, but also to objects with discrete but aligned components and even to those which are almost circular (with present resolution). Second, the sample that is the basis of most of this work is the 3C radio catalogue, which includes only very luminous objects and is probably not typical of most sources at high redshifts. Third, we note (ref. 5 and S.G. Neff, personal communication) that an increasing number of radio sources are unresolved with increasing redshift (over 65 per cent at the highest redshifts), so that the alignment conclusions, by definition, do not apply even to all known objects. Finally, in most (perhaps all) low-redshift cases, the host galaxies are in a state of tidal interaction with a companion[6,7], which is probably the cause of the nuclear activity, but may also independently trigger widespread star-formation. (This also allows the nonalignment of nuclear and galaxy angular momentum). We do not yet know if there are other or more significant nuclear 'triggers' at high redshift. Despite these caveats, it is clear that the new results offer us significant new insights into the processes and cosmic evolution of activity in galactic nuclei.

Rees, in his new work[1], is concerned with the cases in which alignment is observed. He examines the mechanisms that give star formation as a result of nuclear radio activity. His model requires a two-phase gas, such as would be present as a galaxy grows by the gravitational collapse of primordial gas: hot clouds heated by the collapse, and cold clouds trapped by these. Rees suggests that the shock front of a fast moving radio jet (travelling at a tenth of the speed of light) emerging from the nucleus would compress the cold gas, leading to a well synchronized burst of star formation along the jet's path. The mechanism is plausible and must apply in the general situation described. Certainly it can explain the close correspondence between optical continuum and radio structure in the confines of an infall from perhaps 100 kiloparsec. We do not yet know how common this situation is in the observed systems, some of which, being at low redshift, are being observed as they were long after the main epoch of galaxy formation. Indeed, even the earliest known galaxy (at a redshift of 3.4) shows evidence of an old stellar population. But the observed trend of reduced alignment with increasing galactic age (reduced redshift) is certainly expected from Rees's model, which is most effective in the early stages of a galaxy's lifetime: the hot, blue stars created by the radio jet will last 10^8 years or less, and the inflow of gas will carry less luminous stars into the galactic centre (or elsewhere) over a similar period.

A fuller understanding of the processes and their evolution now also requires a look at the ionizing effects of the central radiation, the radio jet material and the young hot stars themselves. Estimates suggest that all these have a comparable influence, and may dominate in different circumstances or at different stages of a radio outburst. A better statistical picture of the individual evolution of radio sources, and how this changes over cosmic time, is needed. At present, we do not know if all radio sources become extended, or whether the bulk velocities are 3 or 30 per cent the speed of light, and whether the central radiation is beamed, either relativistically or by physical collimation. We also do not know how much of the structure that we see at sub-arcsecond levels in high-redshift objects is due to gravitational lensing: early results suggest this may be significant. A comparison of the optical continuum structure and ionized gas structure between unresolved and large and small radio sources will also help distinguish between the principal processes proposed. The data are painstaking to assemble, but they will lead eventually to a direct view of the earliest stages of the history of galaxies. □

ECOLOGY

An inordinate fondness for ants

Robert M. May

HALDANE'S best-remembered remark, that God has 'an inordinate fondness for beetles', was elicited by Jowett's question, at high table at Balliol, as to what his studies had revealed about the deity. Not only are there more named species of beetles than of any other order of organisms (somewhere around 300,000), but Erwin's studies of the beetles found in the canopies of tropical trees suggests the number is, as yet, literally 'inordinate': there may be 10 million or more species of beetles[1,2]. But Haldane's response contains the unspoken assumption that God is more interested in species diversity than in numbers of individuals, for otherwise Jowett might well have been answered with 'an inordinate fondness for ants'. Preliminary analysis by Tobin *et al.* (Harvard University) of the canopy fauna collected by insecticidal fogging from roughly 1,000 m^2 of the Manu National Park in Peruvian Amazonia shows that ants represent 70 per cent of all arthropod individuals, and around 50 per cent of the animal biomass by dry weight; only about 10 per cent of all individuals are beetles (although, at something like 15,000 named species, ants remain much less diverse).

This piece of chauvinism on behalf of ants is an apt motif for the *First International Symposium on Interactions between Ants and Plants**, which ranged broadly over the many aspects of ant–plant associations only just beginning to be fully appreciated. As Davidson and Fisher (University of Utah) observed, the relationships between ants and those plants ('myrmecophytes') that provide them with food and housing, in the form of structures such as extrafloral nectaries and chambers in swellings at the bases of thorns, are still treated in most ecological texts as beautiful cameos, unique and curious examples of symbiotic mutualism largely unrelated to mainstream ecology.

But more detailed studies show patterns and complexity paralleling those in other ecological systems. Thus, Davidson and Fisher have studied the associations of ants with six different species of *Cecropia* plants in Amazonian Peru to test ideas, developed by McKey, about the manner in which habitat-correlated variation in the growth patterns of plants determines their relative investment in chemical and biological defences[3]. Chemical defences, such as tannins and lignins, are relatively costly for a plant to synthesize, but have relatively low maintenance costs and so represent better investments for plants with long-lived leaves. Conversely, the substances produced as benefits to ants by myrmecophytes, not being toxic, may be reclaimed from senescent leaves and shunted to new growth, so that ant defences may be expected to replace phenological defences in plants with continuous leaf production and rapid leaf turnover.

Broadly, these are the patterns Davidson and Fisher found. They made three pairwise comparisons between *Cecropia* species growing at high light intensity, either in disturbed areas along watercourses or in clearings made by people, and species established mainly in small light gaps in forests. Glossing over many details, it appears that the former species have fast growth, high leaf turnover and

* *First International Symposium on Interactions between Ants and Plants*, Oxford, 6–8 July, 1989.

tend to favour biotic defence by means of ants, whereas the latter grow more slowly, have longer-lasting leaves and tend to invest more in chemical defences. Davidson and Fisher went further to suggest how this broader perspective on ant-protection mutualism can explain patterns of parapatric speciation among *Cecropia*, as plants have colonized new habitats. This theme was also developed by McKey (University of Miami), who studied three species of *Leonardoxa* occurring from Eastern Nigeria to Gabon, showing that the evolutionary history of this system — the phylogenetic relations among the plants and among their associated ants — can be inferred from the character of the vegetative and reproductive parts of the plants, particularly as related to the interactions with different ant species.

Another aspect of the complexity of ant–plant systems is the entrainment of many other species in such associations. The larvae of two groups of butterflies, the lycaenids and the riodinids, form mutualisms with ants. DeVries (Smithsonian Tropical Research Institute) showed that ant-tended riodinid species typically use host plants with extrafloral nectaries, feeding on meristem tissues and drinking the nectar (see figure); riodinid species not tended by ants typically are not found on myrmecophytes. The ant species that tend riodinid caterpillars are harvesters of secretions who also tend homopterans (as well as extrafloral nectaries). All of this points to riodinids as examples of the invasion and exploitation of ant–plant mutualisms.

The mutualism between *Piper* plant species and the ant *Pheidole bicornis* is the only known symbiosis in which the plant is believed to produce food for ants only in their presence, in the form of single-celled food bodies within hollow petiole chambers. But Letourneau (University of California at Santa Cruz) described her recent discovery of a *Phyllobaenus* beetle whose larvae appear to have 'broken the code', inducing the plant to produce food bodies in the absence of ants. These beetles can also disrupt ant colonies, resulting in increased herbivore damage to the plant. *Phyllobaenus* seems to be a parasite of a mutualism.

Cushman, Addicott and Breton (University of Alberta) enlarged on the theme that the dynamics of the interactions between species depend strongly on the ecological setting, focusing on ant–plant–homopteran mutualisms. Their detailed investigations of two particular ant–homopteran associations in the western United States showed the dynamics to depend on the density and age-structure of the populations, to be affected by competition and to depend on quality of host plants. Bristow (Michigan State University) carried this further, to address the paradox of why, since essentially all

P. J. DeVries

An Ecuadorian riodinid caterpillar (*Nymphidium* species) drinking extrafloral nectar whilst being protected against predators by ants, which also deter herbivores from feeding on the plant.

aphids feed on phloem sap and produce honeydew, are so few species of aphids tended by ants — fewer than a quarter of aphid species in the Rocky Mountain region.

Bristow showed that phylogenetic inertia cannot explain the observed patterns, because most subfamilies of aphids contain both tended and untended species. Nor are the patterns easy to explain on the basis of varying selective pressures to avoid predation, because ant bodyguards are only one option among many, often mutually incompatible (as, for instance, living in galls on plants). Bristow developed the tentative idea that the quality of the aphid's host plant may be particularly important, through its effect on the honeydew the aphids produce: tending is much commoner for aphids on some plants (*Melus* and *Prunus* species) than on others (*Betula* and *Acer* species), and a detailed study of an occasionally tended aphid species (*Apis nerii*) feeding on oleander (*Nerrum oleander*) showed that aphid colonies feeding on 'high quality' parts of the plant (floral tips rather than leaf meristems) are significantly more likely to attract ants.

Many papers and posters at the meeting dealt with actual or potential applications of ant–plant research. Whittaker (University of Lancaster), for example, surveyed the tradition — long-established in Europe, growing in North America — of introducing wood ants to control insect pests in forests. Emphasizing experimental studies involving broad-leaved trees, he showed that ants of the genus *Formica* do indeed reduce the damage done to trees by herbivorous insects, although the effects vary with season and with the composition of the insect community. Whittaker noted that such manipulative experiments with ants provide a natural and large-scale way of evaluating the impact of herbivorous insect on trees. Dejean (Université Paris-Nord) reported related studies of two species of predatory ants important in protecting orchards in the tropics. The impact of the African weaver ant can be dramatic: these creatures live in nests made from leaves woven together with silk spun by the larvae, and Way has recorded colonies consisting of as many as 150 nests containing close to one million individuals[4].

The opening address by Beattie (Macquarie University) summarized recent advances, but also indicated aspects of ant–plant associations seeming to need more attention. These include the genetics of traits with specific adaptive significance, the biochemical basis of plant-borne rewards for ants, pollination by ants and the extent to which ants affect the gene flow or the spatial organization of gene frequencies in plant populations. Of particular interest to me was Beattie's reminder of the relative neglect of demographic models tailored for ant–plant associations. Andersen (CSIRO Tropical Research Centre, Australia) made a beginning on the task, noting that in their foraging behaviour, patterns of growth and reproduction and in their generally modular nature, ant colonies resemble plants more than animals. This is one more specific instance of the general trend towards constructing population models that go beyond the older Lotka–Volterra metaphors, but which stop short of mind-boggling complexity and a snowstorm of parameters by dealing with specific categories of life histories[5]. □

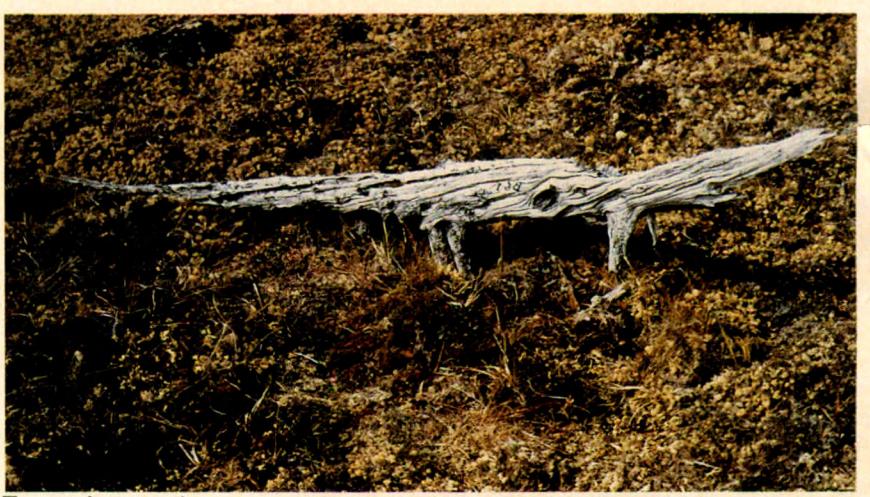
Beauty of the standard model

David J. Miller

REPORTS of Z^0 production[1] at the new electron–positron colliders, the linear collider (SLC) at Stanford and the LEP ring at CERN near Geneva, provided an upbeat start to the European Physical Society's recent high-energy physics conference*. Even though the number of Z^0s recorded so far is only a taste of what is to come, their significance is already apparent in the improved parameter values they indicate for the electroweak part of the 'standard model', which seeks to describe the fundamental physical interactions. Once again, the standard model has survived for another year the tests conducted in several experiments described at the conference, and new ideas emerged on ways to explore and test it further.

The two most pressing experimental questions remain. What are the masses of the top quark and the Higgs scalar particle, if either or both of them exist? There are two well established doublets of quarks — (down, up) and (strange, charm), each with charges ($-1/3e$, $+2/3e$), where e is the charge on a proton. This doublet structure is important in understanding how the quarks couple to the W and Z^0 bosons, the quanta of the weak part of the electroweak interaction, which mediate such processes as nuclear β-decay and neutrino scattering. The quarks in the second doublet are heavier than those in the first, and the charm quark is much heavier than its strange partner (which is why it took an additional 20 years to be discovered). The fifth, beauty quark, which is even heavier, has been well established as a $-1/3e$ charged object for some years. Results from the 60-gigaelectron-volt (GeV) Tristan electron–positron collider in Japan (T. Fujii, KEK) confirmed earlier indications (from PEP at Stanford and PETRA at the German accelerator centre, DESY) that the directional asymmetry in beauty–antibeauty production with respect to the initial positron direction has exactly the size and sign expected if the beauty quark is also a member of a doublet — with the undiscovered top quark as its heavier partner with $+2/3e$ charge (see table). (The alternative names for this pair — bottom and truth — which have distracting connotations, have been dropped.)



Direct searches for decays of particles containing top quarks have continued at the proton–antiproton colliders. The 'signature' of such decays would be isolated high-energy electrons or muons associated with jets of strongly interacting particles such as pions in events with large missing transverse momentum. The decay dynamics can be predicted so the signatures are well defined, but the rate of production falls off as the assumed mass of the top quark is increased. The absence of events has raised the lower limit on the mass to 61 GeV (CERN UA1 experiment), 67 GeV (CERN UA2 experiment) or 77 GeV (Fermilab CDF experiment). The better limit from Fermilab reflects the fact that the collider there gives a higher centre-of-mass energy (1.8 TeV = 1,800 GeV)), than CERN's (640 GeV). Better statistics over the next few years should push Fermilab's limit well beyond 100 GeV.

The Higgs scalar field[2] was introduced to provide the link between the weak forces, carried by the massive W and Z^0, and the electromagnetic force carried by the massless photon. It also provides a mechanism to account for the masses of many particles, including the everyday electron. Within the standard model (as reviewed by L. Maiani, Univ. Rome and R. Barbieri, Univ. Pisa) theoretical upper limits can be placed on the mass of the free Higgs particle, correlated with similar limits on the mass of the top quark. Several workers (including D. Haidt, DESY) have made fits to the full set of available data, incorporating new neutrino-scattering results from the CHARM2 experiment at CERN and the ratio of the rates for W and Z^0 production at the proton–antiproton colliders. They calculate that the top mass must lie between approximately 100 and 160 GeV. As measurements of the masses and widths of the W and Z^0 improve, such fits may be able to predict the mass of the Higgs as well, always assuming that the standard model is true.

As explained above, there seem to be at least three 'generations' of quark doublets in the standard model. These are matched with three generations of lepton doublets; (electron, electron neutrino), (muon, muon neutrino) and (tau, tau neutrino). The SLC measurements of the shape of the Z^0 resonance favour the existence of only these three kinds of neutrino[1]. This conclusion is supported by the ratio of the W and Z^0 production rates in proton–antiproton collisions (CDF at Fermilab, UA2 at CERN). Some of the uncertainties in interpreting the W/Z^0 ratio were removed by data reported by NMC (New Muon Collaboration) workers at CERN (J. Nassalski, Univ. Warsaw) on the momentum distribution of the quarks inside a proton or an antiproton. (Such distributions are needed when calculating collision rates at a proton–antiproton collider because every quark which takes part in an interaction carries only a fraction of the momentum of the projectile, the rest being shared with the 'spectator' quarks and other material. Electron–positron colliders do not have this problem.) As M. Rees (Univ.

* *High Energy and Particle Physics*, Madrid, 6–13 September 1989.

Spruces not warming to the greenhouse

THE environment's response to long-term climate changes is much debated. With the aid of mediaeval spruce remains such as shown above, Serge Payette and colleagues discuss on page 429 of this issue the effect of a series of changes over the past 1,000 years indicating a period of cool weather (AD 1305–1435), a warm period (1435–1570) and the little ice age (1570–1850). From analyses of the tree rings and growth forms of subfossil spruces from northern Canada, the authors find that at these high latitudes (where greenhouse warming should be particularly pronounced), this species flourished even at marginal sites during the warm period preceding the little ice age, whereas the recovery during the present warming is significantly delayed. In part, ecological damage sustained during the past cold 300 years may account for the delay. □

Cambridge) pointed out in his comprehensive review of the connections between particle physics and cosmology, confirmation of the existence of only three kinds of light neutrino would give an important extra constraint to the cosmologists' picture of how helium nuclei were formed during the hot Big Bang.

The particle family

Particle type	quark		lepton	
Charge	$-\frac{1}{3}e$	$+\frac{2}{3}e$	$-e$	0
Generation:				
third	b	t?	τ	ν_τ(?)
second	s	c	μ	ν_μ
first	d	u	e	ν_e

New results from Fermilab seem to have reopened a debate about symmetry-breaking in the standard model. Long-lived neutral kaons are known to decay about one time in a thousand to a final state of two pions. This is a highly suppressed process which violates a simple quantum mechanical rule called CP conservation. The standard model can explain this — as long as there are three generations of quark doublets — and it predicts that the ratio of the decay rates of long-lived and short-lived neutral kaons to two neutral pions will be slightly different from the equivalent ratio for decays to two charged pions. At Madrid, workers on CERN's NA31 experiment confirmed their earlier result[3] which established this difference. But the Fermilab E731 collaboration now claims, with similar precision, to see no difference between the two ratios. The results are only two standard deviations apart, so there is no crisis yet. But it is important to know the mechanism for CP violation in kaon decay, because a related process, at much higher energies during the early milliseconds of the Big Bang, provides the only plausible explanation given so far for the fact that our Universe is made of matter without equal amounts of antimatter.

The standard model explains nonconservation of CP in kaon decay by assuming that virtual beauty quarks make a very small contribution to the decay amplitude. This will happen only if the beauty quark can decay into an up quark, via the weak interaction. The ARGUS group at DESY had claimed two years ago to have seen evidence for such decays, with the rather unlikely production of antiprotons, among other particles, in the final state. That result has now been withdrawn but ARGUS, and the CLEO collaboration at the Cornell electron–positron machine CESR, reported evidence for the much more plausible decay of a beauty quark into an up quark accompanied by an electron and a neutrino. They look at events in which particle–antiparticle pairs of mesons containing beauty quarks were produced. The beauty quark usually decays to the heavy charm quark (third generation to second generation). If it goes to the lighter up quark (third to first generation), there is more energy available for the final particles. Both experiments find about the same number of extra electrons at the high-energy end of the spectrum, just beyond the limit allowed in decays to charm.

Higher energy means new possibilities in particle physics, so that the news (J. Gunion, Univ. California, Davis) that the American 20 TeV on 20 TeV proton–proton collider, the SSC (Superconducting Supercollider), is to receive its first serious funding from Congress, with the earliest starting date for physics in 1998, was warmly received. J.J. Thresher and K. Potter (CERN) pointed out that Europe is well placed to build an 8 TeV on 8 TeV collider in the LEP tunnel to be ready by 1997. But it was interesting that in his talk on new accelerating techniques, W. Schnell (CERN) suggested that a linear electron–positron collider of 200 GeV on 200 GeV might also be a serious possibility: fits to the standard model predict that the top-quark mass is well below 200 GeV, so that such a machine could product top–antitop pairs and measure the top mass very precisely. This would, in turn, put very tight constraints on the mass of the Higgs particle. The machine might even produce detectable Higgs particles — a result as important to cosmology as to particle physics. The feasibility of such a machine and the scientific case for it are still a little vague, but over the next year or so practical lessons from the Stanford Linear Collider and improved parameters for the Z^0 will make this less so. □

GROUP THEORY

Symmetry breakthrough

Ian Stewart

SYMMETRIES abound in nature and technology. Most living creatures have bilateral symmetry, at least to a good approximation and neglecting internal structure; the same goes for most aircraft. Cylinders, squares, hexagons and other highly symmetric forms occur in innumerable scientific problems. Physicists and chemists in particular have found that the symmetry of a system has a considerable influence on its behaviour. Conventional wisdom, going back to Pierre Curie, holds that symmetric systems behave in a symmetric fashion. It is often useful to bear Curie's principle in mind, but it is now known that for many systems, its naive application may lead to incorrect results. The reason is the occurrence of a phenomenon known as spontaneous symmetry breaking. This behaviour, at first sight paradoxical, occurs when a perfectly symmetric system takes up a state with less symmetry. Recent work of M.J. Field and R.W. Richardson, (*Arch. rational Mech. Anal.* **105**, 61–94; 1989) considerably increases our understanding of the general mechanism by which spontaneous symmetry breaking can occur.

For an example of the phenomenon, imagine a perfect cylindrical shell, compressed from both ends by a uniform force. This system has circular symmetry, that is, it remains unchanged under arbitrary rotations about the axis of the cylinder. However, if the compression is sufficiently large, then both in theory and in practice the cylinder will buckle into a shape that no longer has complete circular symmetry. Oddly enough, the initial buckling is usually to a state that still has some symmetry, with patterns of ripples around the circumference of the cylinder that repeat at specific angles, like a smoothed version of a regular polygon.

There are many different types of symmetry, and many different examples of spontaneous symmetry breaking. As in the example of the buckling cylinder, there is a marked tendency for at least some, and usually rather a lot, of the initial symmetry to survive. The fundamental theoretical problem is to determine in full generality, for each type of initial symmetry, just how much should survive. The 'folklore' belief, based on the experience of many special cases, is 'as much as possible'. But this is not always correct. Examples of systems with spherical symmetry (P. Chossat *C. r. hebd. Séanc. Acad. Sci. Paris* **297**, 639–642; 1989; R. Lauterbach *Contemp. Math.* **56**, 217–222; 1986) show that sometimes less symmetry survives than one might expect. The work of Field and Richardson shows that such exceptions are more common than anticipated, and helps to explain why and how exceptions occur.

First, return to the buckling cylinder and ask two questions: where did the symmetry go, and why? 'Why' is largely a matter of stability. In a theoretical model, the circularly symmetric state continues to

exist even at high levels of compression. But it becomes unstable at some threshold value, corresponding to physical buckling. The existence of this threshold is easily verified in specific models. It is to be expected on physical grounds: no realistic cylindrical shell can withstand an arbitrarily high load. If the perfect cylindrical state is unstable, then the system must take up some stable state, which necessarily cannot be circularly symmetric.

'Where' is more subtle. In an idealized model, a whole range of buckled states occur. They all have the same shape, but differ from each other by rotations through arbitrary angles. For example, suppose that in some chosen reference frame there is a stable state in which the cylinder buckles outwards at positions placed 0°, 90°, 180° and 270° around its circumference. Then there is also a stable state for which the buckling occurs at 1°, 91°, 181° and 271°, or for 17°, 107°, 197° and 287° and so on. The original circular symmetry of the single unbuckled state is smeared out across an entire family of buckled states; the individual states lose symmetry but the family as a whole retains it. In practice, tiny imperfections will favour one member of this family rather than another. For example, if the shell has a weakness, this will encourage buckling in that direction. Nevertheless, the idealized model determines the possibilities from which the final selection is made.

To formulate the general problem of spontaneous symmetry breaking, one must make precise the idea of symmetry itself. This is done in the time-honoured way, using group theory. The symmetries of a system are defined to be those transformations that preserve its structure, and the set of all such transformations is called its symmetry group. For example, in a circularly symmetric system the transformations are all possible rotations. The symmetry is said to break if it changes to a smaller group, that is, a subgroup. The fundamental problem of symmetry breaking becomes a question in group theory: given the original symmetry group, which subgroups will occur after the symmetry has broken? The 'folklore' belief becomes the maximal isotropy subgroup conjecture: the subgroups that occur should be the largest ones possible.

Field and Richardson study this question for an important class of symmetry groups, known as Weyl groups. They can be loosely described as the transformations given by a multidimensional kaleidoscope. Weyl groups arise throughout mathematics. In particular, a great deal is known about equations whose symmetries are those of a Weyl group, and Field and Richardson exploit this information to the full. They introduce a new technique, the theory of 'equivariant transversality', which has been worked out over the past decade by Field and E. Bierstone. This lets them reduce the maximal isotrophy subgroup conjecture to a matter of counting geometric dimensions, which they solve.

The end result is that the conjecture is true for some Weyl groups (including those said to be of type A_k, B_k and F_4) but false for others (notably those of type D_k). Indeed they show that its truth for type B_k automatically renders it false for type D_k. The reason is that each group of type D_k is contained as a subgroup in the group of type B_k. For instance, B_4 consists of all permutations of four coordinates, together with all possible combinations of changes of sign: it contains transformations such as $(x_1, x_2, x_3, x_4) \rightarrow (-x_2, x_4, -x_3, -x_1)$. Type D_4 is similar, but contains only half as many transformations, namely those for which the total number of minus signs is even.

Field and Richardson verify that the geometry associated with the group B_4 implies that the maximal isotropy subgroup conjecture is true for B_4. Therefore, any equation with B_4 symmetry has a known set of solutions, corresponding precisely to the different maximal isotropy subgroups — the ways to retain as much symmetry as possible. Some of these solutions also correspond to maximal isotropy subgroups of D_4, but others do not. Now any equation with B_4 symmetry can also be considered as having D_4 symmetry (by 'forgetting' the other half of B_4 that does not belong to D_4). So we have found an equation with D_4 symmetry that disobeys the conjecture, as far as D_4 on its own is concerned. A more delicate analysis shows that such solutions persist even if the equation is perturbed slightly, and hence are not just 'accidents' occurring with zero probability.

This example shows that the existence or nonexistence of symmetry-breaking solutions may involve geometric features associated with auxiliary groups, in addition to the group from which or to which symmetry breaks. By using the information gained in these examples, Field and Richardson have constructed many more examples, yet to be published, for which the maximal isotrophy subgroup conjecture fails, including some for which it fails in fairly drastic fashion.

The theory of equivariant transversality is a creation of pure mathematicians, invented for reasons of mathematical elegance and completeness, and was not originally motivated by questions in applied science. That it turns out to be precisely the tool required to obtain a basic insight into spontaneous symmetry breaking was not foreseen. So this is an interesting case where a problem that has refused to yield to a head-on attack has succumbed to an indirect approach from a totally unexpected direction. □

Ian Stewart is in the Mathematics Institute, University of Warwick, Coventry CV4 7AL, UK.

DAEDALUS

Air suspension

AIR TRAVEL these days, says Daedalus, is becoming increasingly slow, tedious and unpleasant. So he proposes a new way of getting through the air. It combines the best features of the balloon and the aerial cableway. His new 'Gasway' uses a hollow, gas-filled, buoyant cable.

The great advantage of this system is that the cable is effectively self-supporting, so the anchoring pylons can be very many kilometres apart. The cable will 'hang' between them in vast, noble, inverted catenaries, rising far into the atmosphere at the centre of each span. To load it evenly, the vehicles moving along it must be quite regularly distributed — a succession of aerial trams rather than one concentrated train.

DREADCO's aerodynamicists are modelling the behaviour of the Gasway under different loads and in various atmospheric conditions. Cunningly, Daedalus will make his trams a trifle tail-heavy, so that they load the supporting cable unevenly. The resulting inclination of the cable will be propagated ahead of the moving tram. It will generate considerable lift on the cable, tending to cancel the weight of the tram. The transient vehicle loads on the cable will thus be minimized, leaving irregular wind forces as the main problem. Modern carbon-fibre-reinforced, plastic-film materials are so strong for their weight that even a long span of cable should safely withstand quite vigorous gusting. It will, however, flex and wander a good deal. But a tram on the cable will in effect experience the wind force average over hundreds of metres of cable, and should be far more stable than a small aircraft or free-floating balloon in the same conditions. And most of the journey will be in the high atmosphere where the wind is pretty steady.

A Gasway will be cheap and easy to operate. Navigation and air-traffic control problems will vanish, and so will huge out-of-town airports: the cable can easily descend straight into a town-centre terminus. And the system will be very secure. A tram cannot collide with other trams on different routes or be hi-jacked to Beirut.

The main problem is the choice of the gas. Such a large volume of helium would be very costly. Daedalus's brilliant solution is to use natural gas, which is mainly methane, much lighter than air, and has to be piped around the country anyway. A combined air-transport and gas-distribution system should be very profitable.

The obvious snag is the risk of fire. Daedalus plans to add a small amount of a halocarbon radical-trap fire-extinguishing agent to his methane, thus making it effectively non-inflammable. This could easily be frozen out again as the gas leaves the Gasway. David Jones

Rocks that are too hot to handle

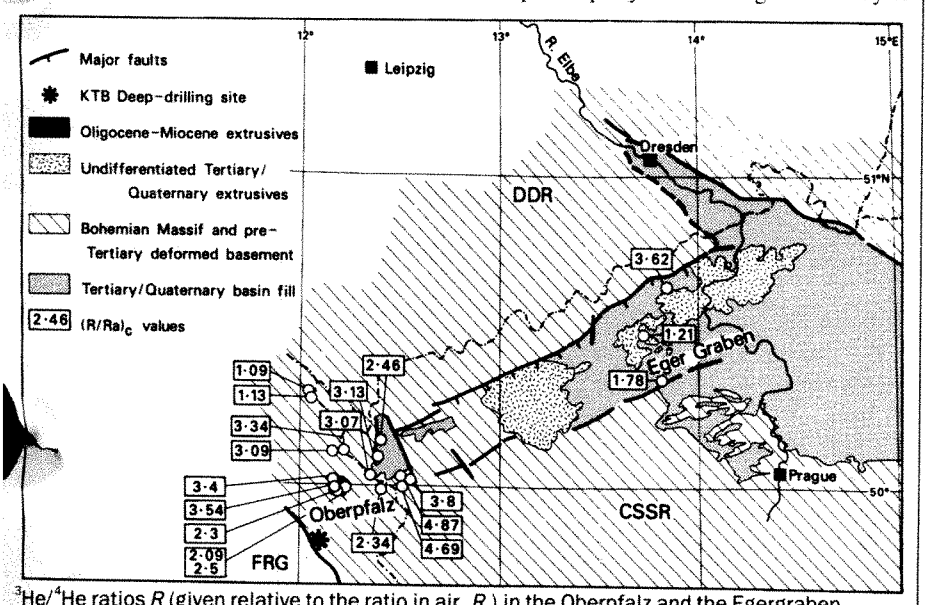
SIR—It has recently been announced[1,2] that the German Science Foundation (DFG) project to drill a bore-hole (KTB) 14-km deep to investigate the deep structure of the Earth's crust has had to modify its objectives, because the unexpectedly high temperatures encountered (about 110 °C at depths of 3,700 m)[3] indicate that at the target depth the rock will be too hot to drill. This is despite the fact that the drilling site in the Oberpfalz (see figure) was chosen because of the predicted low temperatures at depth.

Questions arise as to why these predictions[4], made on the basis of thermal conductivity, magnetic, magnetolluric and seismic reflection studies, were misleading, and whether the present situation could have been predicted by other means. Shortly before the final choice of site was made, we performed isotope analyses of trace amounts of helium dissolved in deep well waters in the Oberpfalz area[5]. We expected to find $^3He/^4He$ values close to 10^{-8}, the average natural production ratio for He in the crust. To our surprise we measured some values greater than 10^{-6} (see table). In the absence of excess ^3He derived from the decay of tritium generated by atmospheric testing of nuclear weapons, this could be explained only by the presence of a significant proportion of primordial He released from the Earth's mantle. This situation is most commonly found in active volcanic regions, particularly the axial zones of actively spreading mid-ocean ridges, which have a $^3He/^4He$ ratio of around 10^{-5}.

These were some of the highest ratios then measured in continental Europe. We took further samples from the Egergraben, a young half-graben structure that displays clear evidence of recent volcanic activity. Here the values were higher still (see table), very close to those on ocean ridges. The rift is 150 km long and trends ENE–WSW directly into the Oberpfalz.

We concluded[6] that the only plausible explanation of such He compositions in continental areas was that they had been modified by transient releases of mantle-derived volatiles associated with the emplacement of basaltic magmas in the crust. It is possible that the Egergraben rift is propagating to the west, that we are detecting the precursors to that process and that He serves as a tracer for a geological process that is otherwise undetectable (E.G., R.K.O'N. and E.R.O., manuscript in preparation). Moreover, we showed that if the contemporary emplacement of basalt was as widespread as He measurements made throughout Europe indicated, over geological time such emplacement has probably made a major contribution to the growth of the continents[7].

The observations of high temperatures in the Oberpfalz seem to provide some support for our hypothesis. They could, however, have a completely different explanation: abnormal crustal concentrations of heat-producing elements or refraction of heat flow by complex geological structures are both conceivable, but neither quantitatively explains the observations. Their contribution should, however, become apparent from further drilling, which should also show whether the temperatures have been raised above conductive equilibrium values by hot fluids ascending convectively through fissures and pore spaces in the rocks.



If the emplacement of magmas was too recent for them to have yet crystallized, they will still be at a temperature of about 1,000 K and the thermal gradient will steepen rapidly as the magmatic body is approached. If the body has solidified sufficiently, it may be possible to drill into it. In either case the body is probably sufficiently young for the thermal transient associated with its emplacement not to have yet reached the surface and for the helium degassed from it not to have entirely dissipated. The thermal anomaly observed could thus be generated by a family of igneous bodies that might be the forerunners of surface volcanoes such as are seen in the Egergraben.

Our prediction, based on the He measurements, that the KTB Project "drilling will provide some surprises"[6] seems to have been vindicated[8].

DNA-binding motif

SIR—We wish to point out that a basic motif implicated in sequence-specific DNA binding in the Fos/Jun family of proteins is structurally conserved in the Myc proteins and in other regulatory factors that are proposed[1] to contain amphipathic helix–loop–helix (A-HLH) domains. In addition to the Myc proteins, this group includes the muscle determination factors MyoD1 and myogenin, the kappa enhancer-binding proteins E12 and E47, and the polypeptides encoded by the *Drosophila* genes *daughterless*, *twist* and *achaetescute T4/T5*.

In the Fos/Jun proteins, the 'leucine zipper' region has been shown to be critical for dimerization, while sequence-specific DNA binding by Fos/Jun requires the integrity of a basic motif immediately amino-terminal to the leucine zipper[2,3]. Similarly, in the case of the E12/E47 enhancer-binding proteins, integrity of the proposed A-HLH domain has also been shown to be important for protein dimerization and DNA-binding activity[1]. The carboxy-terminal region of c-Myc (amino acids 369–439), containing both the leucine zipper and A-HLH motif, has been shown to be sufficient for protein oligomerization *in vitro*[4].

The incorporation of domain definitions in a visual comparison of the region just amino-terminal of the dimerization motifs in the Fos/Jun and A-HLH proteins reveals a 17-amino-acid block of structural similarity (see figure). The highest similarity (about 45 per cent with conservative substitutions) is between the Fos and Myc proteins. We noted that this region is positioned exactly in register with hydrophobic amino acids critical for the helix–helix interactions that mediate dimerization by the leucine zipper and (proposed for) the HLH helix 1. Strikingly, the region overlaps that part of the basic motif in Fos which is necessary for specific DNA-binding to the AP1 recognition sequence[2-4]. The significance of this similarity is founded on the incorporation of biological meaning (that is, definition of domains) into the search. (Homology search algorithms give this similarity a high quality score when the Fos basic motif region is used in database comparisons.)

Basic motif and oligomerization domain similarities between Fos/Jun and A-HLH gene regulatory proteins. The single-letter amino acid code is used; B represents a hydrophobic amino acid. Identity is noted by dashes, similarities by dots. Amino-acid sequence is shown for mouse c-Jun (254–311), JunB (239–314) and JunD (261–318) (see ref. 6); mouse FosB (154–211), Fra-1 (106–163) and c–Fos (136–195) (see ref. 7); human c-Myc (337–439), N-Myc (384–462), L–Myc (280–363), MyoD (99–164), E12 (327–393), E47 (327–393), *daughterless* (554–613) and *twist* (357–407) (see ref. 1).

On the basis of this structural similarity, we propose that the basic motif in the Myc and A-HLH proteins is likely to encode a sequence-specific DNA-binding function. With regard to the Myc proteins, though a specific DNA recognition site is yet to be identified, our proposal contrasts with suggestions that this function is encoded in the A-HLH domain[1], or in a more amino-terminal region (amino acids 285–318) required for nonspecific DNA binding[5]. The structural similarity between A-HLH and Fos/Jun proteins in this domain suggests that these proteins are part of a large 'basic motif' family evolutionarily related via their DNA-binding structures. This family would contain at least three subsets comprising members that contain only leucine zippers, only A-HLH domains or both.

Memory T cells

SIR—Haregewoin *et al.*[1] have reported the exciting finding of a human T-cell line expressing a γδ T-cell receptor (TCR). The T-cell line ($CD2^+$, $CD3^+$, $CD16^-$) responds to PPD (purified protein derivative) and a mycobacterial heat-shock protein of relative molecular mass 65,000 (65K HSP) in a self-restricted fashion. The line was obtained by stimulation of peripheral-blood mononuclear cells with PPD, followed by depletion of CD4, CD8 and αβ TCR expressing cells. Cells were maintained by repeated restimulation with autologous antigen-presenting cells, antigen and T-cell growth factor.

We have shown that recall-antigen-reactive 'memory' T cells occur with high frequencies in freshly isolated $CD45R0^+$/$UCHL1^+$, but not $CD45RA^+$, populations of human lymphocytes[2]. Haregewoin *et al.* speculate in reference to this work, that their line may be derived from memory T cells, as it is $CD45R0^+/UCHL1^+$ and $CD45RA^-$. We would like to point out that after activation *in vitro*, $CD45RA^+$ T cells lose CD45RA (refs 3–7) and acquire reactivity with the CD45R0 reagent UCHL1 (refs 6 and 7). The expression of CD45R0 on Jl-2 dependent T-cell lines and clones is, therefore, a regular finding which does not provide any information on the CD45 phenotype of their precursor cells.

Our group has recently demonstrated the expression of CD45R0 by a proportion of freshly isolated γδ TCR T cells. This proportion is low in very young children and rises with age[8], as is the case for αβ TCR T cells. This observation is consistent with the accumulation of γδ memory T cells, a possibility that could be tested now that some antigens to which human γδ T cells respond have been defined[1,9,10].

The most accurate and up-to-date guide to the status and development of human therapeutic proteins . . .

Genetically Engineered Human Therapeutic Drugs

D. Copsey and S.Y.J. Delnatte, *Pantech Partners*

Genetically Engineered Human Therapeutic Drugs is a comprehensive reference source that provides up-to-date information on human therapeutic proteins in a convenient, logically organized format. Based on evidence from clinical studies reported in the academic, clinical and biological research journals, the information provided in this work is among the most accurate and objective information available.

PART I: Clinical Drug Development

Part I consists of reviews of 77 proteins under 18 therapeutic categories. These reviews examine the clinical research being undertaken in the major unsatisfied therapeutic areas. Where available, each review provides information on: Therapeutic Indications • Clinical Research Background • Clinical Studies.

PART II: Commerical Drug Development

Part II examines 90 proteins under 25 therapeutic categories currently being developed for their commercial potential as therapeutic drugs. It is organized alphabetically by generic rDNA protein. Following the introductory section for each protein, are tables organized by stage of development: Launched Products • Registered / Approved Products (Not yet launched) • Products in Clinical Trials • Products in Research or Pre-Clinical Development • Products under Clinical Agreements

CHIMIX 3®

The simple solution for combining chemical formulas and text

CHIMIX3: Practical and Efficient

• Interactive Editor for which no complex language is needed. CHIMIX3 allows the user to create simply all variations of chemical documents.

• Single, double and triple bonds, 5 and 6-apex rings and polycyclic compounds are immediately seen on the screen with the press of only one function key.

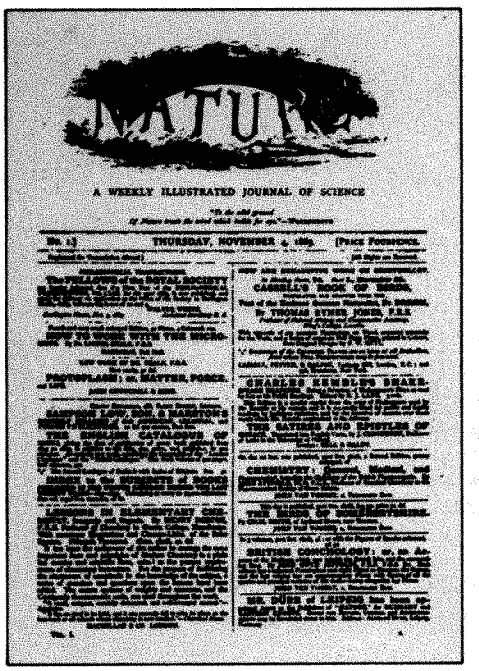
With CHIMIX3, flexibility in your documents.

• 5 character sets, including full Greek and international alphabet, operators and logical symbols.

• Mathematical formulas are easily constructed via functions keys, with size changes appearing immediately on the screen.

• Justification of text and formulas, search and replace, insert and tabulation as well as other standard word processing features.

CHIMIX3 is available for IBM XT, AT, PS/2 or compatibles running MS-DOS with at least 640K memory. EGA, VGA, Hercules and Olivetti and HP vectra graphics modes are supported. Usable with most laser printers.



Innovation and professional quality now at your fingertips.

IBP PC and PS/2 are registered trademarks of International Business Machine Corporation. MS-DOS is a registered trademarkof Microsoft Corporation. Hercules is a registered trademark of Hercules Computer Technology.

Quantikine™

For the Precise Quantitation of Cytokines.

ELISA Kits for TNF-*a*, IL-1β*, IL-4*, IL-6

R&D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive: linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.

Precise: well-to-well CV <8%

Specific: results not influenced by the presence of other cytokines.

Accurate: eliminates the inherent imprecision of bioassays.

Rapid: simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample...Incubate (2 hours)...
Wash...Add Detection Antibody...
Incubate (2 hours)...Wash...
Develop...Read Results.

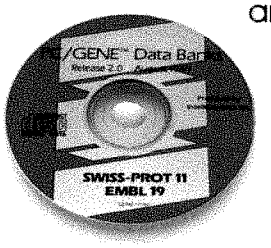
Realize the Potential of Your Sequence Data



Once you have your protein or nucleic acid sequence, you can analyze it in hundreds of different ways with PC/GENE™.

PC/GENE's programs include primary and secondary structure analysis, statistical analysis, site detection for specific regions within a sequence, cleavage and restriction analysis, data base searching and gel assembly. With PC/GENE, you can search for unique regions to make oligonucleotide primers for PCR*, and confirm the absence of secondary binding. Running on IBM PC's and compatibles, PC/GENE is menu and mouse driven, so it is easy to use even if you have little computer experience.

PC/GENE's unique functionality incorporates the latest research methods to provide you with better scientific tools.

- Finds any of 180 different protein patterns in just a few minutes, each accompanied by a complete list of literature references.
- Predicts the chemical and physical properties of proteins using any of 57 published tables, or your own.
- Designs primers for site-directed mutagenesis and determines the effects of the mutation on the resulting protein.

A CD-ROM containing the SWISS-PROT protein and EMBL nucleic acid data banks is included with PC/GENE.

We believe that the best way to try PC/GENE is in your own lab, so IntelliGenetics offers a no-obligation 30-day trial of the full package. Call our toll-free number 1-800-876-9994 for details.

IntelliGenetics, Inc.
700 East El Camino Real
Mountain View, CA 94040

SOFTWARE

FROM OXFORD

DESKTOP MOLECULAR MODELLER

New plotter output facility

'DTMM represents one of the best and least expensive molecular modelling software programs currently available... A major breakthrough in the 3D colour display of the shape of inorganic and organic molecules...'

Professor Brian Hathaway

This popular program now comes with a plotter output facility. You can use ***Desktop Molecular Modeller*** to make colour plots of molecules for use in presentations and papers.

- **Display molecules and fragments of up to 1400 atoms** choose between 6 display styles
- **Manipulate and edit molecules** break and make bonds, delete and add atoms, and change atom types
- **View molecules** project structures along bonds or onto planes; rotate, rescale, and pan in real-time
- **Validate new structures** check bond lengths, angles, and van der Waals radii, or execute an energy minimization routine
- **Output structures to an HPGL plotter** for presentations and papers
- **Record a 'slide show'** generate sequences of images for demonstration purposes

Price: £250 in the EEC / US$495 elsewhere, plus postage and packing (UK customers add VAT at 15%). Ask for our attractive rates for multiple installation.

Department licence: For installation on up to five PCs for teaching purposes within a department or laboratory. Available to educational establishments only.

Site licence: For installation onto an unlimited number of PCs within an agreed site. Available to both educational establishments and commercial users.

Hardware requirements: IBM PC, XT, AT, or PS/2 (or full compatibles) with 512K RAM, DOS version 2.0 or higher. IBM CGA, EGA, and VGA or Hercules Graphics card. Optional: Microsoft MS-DOS standard mouse (or compatible), maths coprocessor, HPGL-compatible plotter.

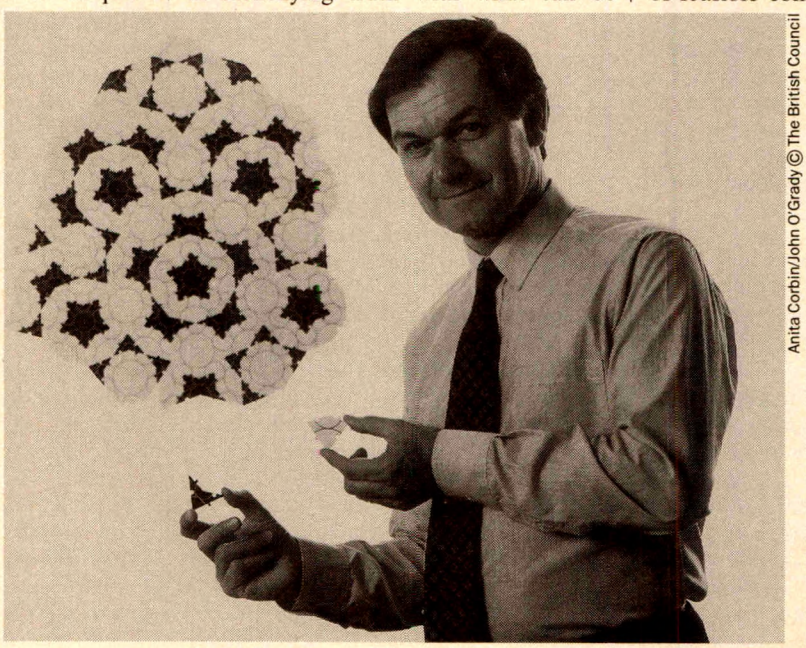
People are different



Christopher Longuet-Higgins

The Emperor's New Mind: Concerning Computers, Minds, and the Laws of Physics. By Roger Penrose. *Oxford University Press: 1989. Pp.466. £20. To be published in the United States in November, $24.95.*

ONE cannot imagine a more revealing self-portrait than this enchanting, tantalizing book. The Rouse Ball Professor of Mathematics at the University of Oxford might be thought of as a dusty old don with a formidable reputation in some unheard-of field and an occupational inability to talk about any topic of general interest. Roger Penrose reveals himself as an eloquent protagonist, not only of the wonders of mathematics, but also of the uniqueness of people, whom he regards as mysterious, almost miraculous beings able to burst the bounds of mathematical logic and peep into the platonic world of absolute truths and universal objects.

The book's title is a storm warning for a furious attack on strong AI (artificial intelligence) — the philosophical view that computers 'really' have minds, and that any computational device, even a thermostat, has mental qualities of some sort. From this postulate it would seem to follow that the human mind could well be superseded by a sufficiently powerful computer, a prospect that most people find either alarming or absurd. Penrose decides to demonstrate its absurdity by mathematical argument, the most powerful intellectual weapon known to man. He refers with approval to John Searle's attack on strong AI, but takes an even more extreme view in dissenting from Searle's surprising concession that "Of course the brain is a digital computer. Since everything is a digital computer, brains are too". "It is my intention in this book", Penrose explains, "to try to show why, and perhaps how, this need not be the case".

For his critique of the contention that the human brain is a digital computer Penrose marshalls a range of arguments from mathematics, physics and metamathematics. One of the book's outstanding virtues is the trouble its author takes to acquaint his readers with all the facts they need in order to understand the crucial problems, as he sees them, and all the steps in any argument that underpins an important theoretical conclusion. He quotes, in his foreword, the dictum that each mathematical formula in any book will cut down its general readership by half, but defies this maxim by quoting a number of equations far greater than the binary logarithm of the world's population. His serious readers will be grateful to him for explaining *why* there are problems in identifying truth with what can be proved, or in equating reality with what can be measured; others will be happy in the company of a guide whose quips they can enjoy even if they cannot always follow his allusions.

Anita Corbin/John O'Grady © The British Council

Roger Penrose — giving a piece of his mind.

In his first attack on conventional AI wisdom Penrose develops an argument very similar to the one that John Lucas first propounded in the early 1960s, to the great annoyance of the computer scientists of that generation. The human mind cannot, he maintains, be a mere computer following through the steps in an complicated algorithm, because there can be no single algorithm for deciding *all* the questions that a mathematician might pose — and answer. In order to explain why, he gives a brilliant and intellectually strenuous account of algorithms and their implementation by Turing machines. But having made his point Penrose unexpectedly expresses some qualms about the relevance of these particular concepts to the philosophy of mind:

> It has been helpful in the above description to use the anthropomorphic term 'know' in reference to an algorithm. However, is it not *we* who are doing the 'knowing' while the algorithm just follows the rules we have told it to follow? Or are we ourselves merely following rules that we have been programmed to follow from the construction of our brains and from our environment? The issue is not really simply one of algorithms, but also a question of how one judges what is true and what is not true. These are central issues that we shall have to return to later.

The next stop on this extraordinary cosmic tour is the kingdom of pure mathematics, illustrated (how better?) by the astonishing Mandelbrot set, and pedagogically enriched by an exposition of complex numbers. The idea of non-recursive mathematics, beyond the reach of feasible computation, is used to illustrate the feebleness of proof and the power of insight in the mathematician's quest for truth. The author quite rightly yields to the temptation to reminisce about some of his own discoveries, including the famous 'Penrose tiles', with which one can tile the plane, but only in a non-periodic fashion. He returns to the tiles much later in a visionary passage on how the recently discovered 'quasi-crystals', which give the appearance of possessing five-fold symmetry axes defying the principles of crystallography, might emerge from their mother-liquor by a quantum-mechanical mechanism possibly bearing some analogy to the way in which the mind distils coherent ideas out of a mass of inarticulate intuitions.

Penrose explains that his book was inspired by the conviction that we shall not understand how our brains work until we have a much better understanding of *physics*. The greater part of the book is, accordingly, devoted to the findings of classical mechanics, relativity and quantum mechanics rather than the more obviously relevant disciplines of philosophy, psychology and physiology. One after another the SUPERB theories of physics, as Penrose dubbs them (other theories being merely USEFUL or TENTATIVE) have run into acute difficulties of internal consistency or physical interpretation. His account of the problems and paradoxes of contemporary physics is delivered with all the assurance of a leading cosmologist — one who believes, incidentally, that a revolution in quantum gravity is about to break upon the scientific world. Not only, according to Penrose, could this fill an awkward gap in the quantum theory of observation

(relating to the circumstances under which wave functions are deemed to collapse), but it might very well resolve the apparent discrepancy between the time-reversibility of the laws of dynamics and the manifest irreversibility of the second law of thermodynamics and the subjective arrow of time. Central to the latter problem is Penrose's 'Weyl Curvature Hypothesis', which distinguishes sharply between initial and final singularities in cosmic space–time. As for the collapse of wave functions, he speculates that this happens whenever a "significant" amount of space–time curvature causes quantum superposition to fail. The latter is perhaps the most TENTATIVE suggestion in the book, and the author is duly cautious in advancing it.

Having journeyed to the ends of the Universe in search of possible enlightenment, Penrose wistfully bids farewell to big bangs and black holes, and resumes his reflections on the mind — or rather, on the brain as seen through the eyes of his Oxford colleagues in psychology and neurophysiology:

> The picture of a superb computing device seems to be presented to us. The supporters of strong AI would hold that here we have a supreme example of an algorithmic computer . . .

Will our hero succumb to this persuasive image? Not he. There is an ace up his sleeve — "the phenomenon of consciousness". But the philosophical problems surrounding this concept prove so bewildering that Penrose abandons logical argument for rumination upon the nature of free will, the anthropic principle, creative inspiration and the sensing of necessary truths. There is just one cat he refrains from putting among the neuroscientific pigeons, namely the suggestion that the brain is actually a 'quantum computer' of the kind recently defined by David Deutsch. He raises this possibility, but concludes that the brain is too "hot" an object to preserve quantum coherence for any length of time.

The Emperor's New Mind might have been merely an attack on a particular group of philosophers or computer scientists, or on some of the wilder claims of the artificial intelligentsia. It might, with more profit, have examined in detail some of the honest hard work that has been done, by theoretical linguists and cognitive psychologists, in attempting to describe as accurately, as elegantly and in as much detail as possible how the human mind actually *does* work; Penrose must know that it is the details in which the soul of a work of art largely resides. As it is, his book is the testament of a brilliant man wrestling desperately — and unashamedly — with the deepest problems of metaphysics. He does not solve any of them, but his questions are greatly preferable to most people's answers. His book aptly illustrates his own thesis that philosophically inexpert scientists may have at least as much to contribute to human thought as scientifically ignorant philosophers. □

Christopher Longuet-Higgins is in the Centre for Research on Perception and Cognition, University of Sussex, Brighton BN1 9QG, UK.

Robert Temple

The Galileo Affair: A Documentary History. By Maurice A. Finocchiaro. *University of California Press: 1989. Pp.382. Hbk $50, £31.25; pbk $12.95, £8.*

Sidereus Nuncius or the Sidereal Messenger. By Galileo Galilei. Translated with introduction, conclusion and notes by Albert Van Helden. *University of Chicago Press: 1989. Pp.127. Hbk $29.95, £19.25; pbk $7.95, £6.25.*

THE trial and condemnation of Galileo by the Roman Catholic Inquisition in 1633 is the classic example of the triumph of mediocrity over genius, and the suppression of the truth in the interests of the Great Lie. The central issue was quite clear. In Galileo's own words, it was this: "who wants the human mind put to death?".

Much has been written about Galileo's trial. But it is only now that we can steep ourselves in the atmosphere of the incident and read the very words of the main protagonists, often from their own secret correspondence or from private Inquisition papers. For the first time, all the relevant documents are made available in English in Maurice Finocchiaro's marvellous translation.

There is a pernicious trend amongst historians today which discourages the publication of original source material. Only tedious and opinionated 'discussion and analysis' by self-styled 'experts' is held to be interesting or worthwhile. The reason, of course, is that many historians want to set themselves up as the clergy who will mediate between historical truth and the public. So strong is this trend that some of those who have dared to publish original documents are ostracized and attacked in the way that Cranmer was savaged in the sixteenth century for daring to suggest that ordinary people should be allowed to read the Bible for themselves. Finocchiaro has braved fashion to enable us to step inside the Inquisition proceedings. For this we cannot be too grateful.

Reading through the actual documents for the 20-year period of 'the Galileo Affair', one is struck by the honesty and genius of Galileo and we can see clearly that he could not possibly have done other than recant. The Medicis of Florence were so deeply in political jeopardy over their passionate support of him against the Pope that if he had been awkward, and made himself a martyr, it would have brought incalculable disaster upon his patrons.

As for the hypocritical and mindless attitude of the Catholic thought police, whose only interest was the relentless imposition of uniformity and destruction of any trace of independent thought, we have the Pope himself as an example. In his secret diplomatic correspondence, the Florentine Ambassador describes this encounter:

> I humbly begged His Holiness to agree to give Galileo the opportunity to justify himself. Then His Holiness answered that in these matters of the Holy Office the procedure was simply to arrive at a censure and then call the defendant to recant. I replied: Does it thus not seem to Your Holiness that Galileo should know in advance the difficulties and the objections or the censures which are being raised against his work. . .? He answered violently: I say to Your Lordship that the Holy Office does not do these things and does not proceed in this way. . . the Holy Office is not in the habit of hearing defenses. . . .

As we all know, the grey men won and Galileo's *Dialogue on the Two Chief World Systems* was not removed from the Catholic Index of Prohibited Books until 1835. Its principles of putting scientific truth over the words of Scripture was not accepted until 1893, and it was not until 1979 that the Church, in a speech by Pope John Paul II, acknowledged that it had erred in condemning Galileo.

For the proper appreciation of Galileo's genius there is no substitute for reading his *Sidereal Messenger*, a short work charged with the electric excitement of discovery. Published in 1610, it is essentially a scientific newsletter announcing fundamental astronomical discoveries that had been made by means of telescopes of unusually high power for the time. Among the revelations were that the Moon's surface is covered in mountains and valleys rather than being smooth, and the existence of the four principal satellites of Jupiter. The sense of euphoria and joy at discovering such things for the first time in mankind's history is fresh and tangible.

The work has never before been made available in its entirety in a continuous form, with full notes and comment. The introduction, translation and notes by Van Helden are a splendid example of the best scholarship and fullest accessibility. With this *Messenger* and Finocchiaro's magnificent book, we can now truly get to grips with the phenomenon of Galileo and what his life and work should mean to us today. □

The chocolate box problem

Peter Bryant

Autism: Explaining the Enigma. By Uta Frith. *Basil Blackwell: 1989. Pp.204. Hbk £25, $19.95; pbk £8.95.*

THE number of autistic children is tiny (about 4 in 10,000). Yet their plight has always attracted a great deal of attention because the nature of their difficulties poses an intriguing puzzle.

Autistic children have severe social and emotional problems, and they have some striking intellectual difficulties as well. This combination of problems is unusual in itself, but it seems even more curious when one considers the uneveness of their intellectual abilities. They tend to fail dismally in some intellectual tasks, and yet have little difficulty in others. Some display remarkable talents — there are autistic children who draw astonishingly accurate and beautiful pictures, and others who have remarkable musical abilities, and yet can barely speak.

The general interest in autism is reflected in the large amount of research that has been done on the subject, but there has never been an accessible and comprehensive account of this work. Uta Frith, who is one of the leading researchers on childhood autism, has now filled this gap. Her exciting and attractively written book can be divided into two parts. In the first she lays out the facts — the odd combination of symptoms, the possible influence of heredity, the social class and gender differences — and thus sets the puzzle. The aim of the rest of the book is to provide the solution.

In fact two solutions are offered, or at any rate two hypotheses. The first is that autistic children are insensitive to pattern. Most children find it easier to remember a meaningful sentence than a list of disconnected words, but that is not true of autistic children. They are not helped by meaning. They also often fail to spot repetitive patterns in perceptual displays, though such patterns are perfectly obvious to other children. Sometimes the attention that autistic children pay to parts at the expense of the whole actually helps them. They are better than other children at spotting an abstract shape which is hidden within a larger meaningful figure. So Uta Frith argues that their world is fragmented and that it lacks meaning.

Her second theme is that autistic children find it particularly hard to work out what other people are thinking and feeling. She and her colleagues have shown, to take but one example, that autistic children manage perfectly well when asked to arrange some pictures into a sequence that tells a story about a balloon flying away and bursting on a tree, or about someone going to a shop and buying sweets. But they are at a loss when the story concerns a boy's disappointment at not finding something which he had put in a box for safe keeping (and which someone else had stolen). When other people's expectations and emotions are different from the autistic child's they are beyond his comprehension.

Uta Frith links this difficulty to another peculiarity of autism — the fact that autistic children tend not to indulge in 'pretend play'. Normal children, when playing, quite often decide, for example, that a banana can play the part of a telephone, but as far as the autistic child is concerned it stubbornly remains a banana. Uta Frith argues that one has to know about pretence to understand that two people can have different beliefs about the same event. If I pretend that an empty chocolate box is full, I know that I may believe one thing and the rest of the world another about the box's contents. According to Uta Frith autistic children do not understand pretence and thus cannot grasp the fact that different people have different feelings and beliefs. As a result many of the most important aspects of social communication elude them completely. This in turn accounts for their social and also for their linguistic difficulties.

Uta Frith's presentation of these two hypotheses is lucid, entertaining and extremely convincing. There is no doubt that the empirical evidence which supports her ideas is the most exciting that there is on the subject of autism. There are a few objections to be made. Autistic children may have a better understanding of pretence than she suggests: some recent work shows that they do take to pretend play if they are prompted to do so. There is also a certain tension between the two hypotheses. For example autistic children easily rearranged pictures into a story about a balloon bursting, and yet according to Uta Frith's ideas about fragmentation it should have been quite difficult for them to do so. Her explanation is that they have difficulty with broad but not with narrow contexts: but how does one decide what is broad?

These are minor quibbles while the book is without doubt a major achievement. It will have an immense influence, and all to the good, on future research on this topic. □

Signal survey

Gunnar von Heijne

Protein Targeting. By Anthony P. Pugsley. *Academic: 1989. Pp.279. $45, £28.50.*

PROTEIN targeting — that is, the means by which newly made proteins are directed to their final destinations inside or outside the cell — has been among the hottest subjects in molecular and cell biology for more than a decade. Yet it is only with Anthony Pugsley's book that a well-written, integrated overview of the field has become available.

Pugsley starts with two introductory chapters on protein traffic in eukaryotic and bacterial cells, and the main experimental techniques used to study these processes. He then takes a deep breath and dives into his subject, following the sometimes tortuous paths of proteins from the cytoplasm through all the intricacies of the secretory pathway or into the depths of nuclei, mitochondria and chloroplasts.

Throughout, the emphasis is on the structure of the routing signals and on how these are decoded by a battery of cytoplasmic, membrane-bound and intra-organellar proteins that ensure the specificity and vectoriality of targeting and transport. Pugsley provides a unified picture, based on the latest results, with cytoplasmic factors stabilizing 'translocation-competent' conformations of the newly synthesized proteins, organelle-bound receptors recognizing their cognate routing signals, integral membrane proteins possibly serving as translocation machines, and 'chaperones' inside the organelles assisting in the final steps of folding and assembly.

Also discussed are the vesicular communication links between the different stages of the secretory pathway — endoplasmic reticulum to Golgi to trans-Golgi network to plasma membrane or lysosome — and the complementary processes of endocytotic uptake of proteins and other molecules from the cells' surroundings.

The text ends with an appendix describing various ways that our knowledge about protein targeting can be put to practical ends: secretion of heterologous proteins by bacterial, fungal and animal cell cultures; herbicide-resistance by manipulation of chloroplast-targeted proteins; and specific targeting of toxins into the endocytic pathway of tumor cells.

As a befitting finale there is an impressive bibliography with some 1,300 references, essentially complete up to and including 1988. Let us hope that the royalties Pugsley can expect from his book will go at least some way towards covering his no doubt exorbitant photocopying bills. □

Talk across the barriers

Andrew Cossins

Membrane Transport: People and Ideas. Edited by Daniel C. Tosteson. *American Physiological Society, 9,650 Rockville Pike, Bethesda, Maryland 20814. 1989. Pp.414. $75. Distributed by Oxford University Press in Britain, £50.*

Sitting pretty — Isaac Newton, "a very great head of school but not pompous", depicted in a Japanese print *c.* 1869. The illustration comes from the new paperback edition of *Let Newton Be!* (Oxford University Press). The book was reviewed in *Nature* **337,** 28 (1989).

IT MAY be hard for the membrane biologists of today to appreciate fully just how far and how rapidly their subject has progressed in this century. In the 1920s the very notion of a limiting membrane around cells was still controversial. It was only 57 years ago that the bilayer was firmly recognized as the basic ultrastructural component of biomembranes, and only 17 years have passed since the inclusion of protein in the bilayer was formally conceptualized by Singer and Nicholson. Since that time an increasing number of transport systems have been dissected and characterized both at the molecular and submolecular level.

The origins and development of the principles that underpin modern studies are given extensive treatment in *Membrane Transport*, a multi-authored volume written in celebration of the Centenary of the American Physiological Society. The book is wide ranging, starting with detailed accounts of the origins of the bilayer/unit membrane concept, moving through the principal modes of transport across membranes to ion selectivity and bioelectricity. Finally, the emergence of concepts in whole-cell phenomena such as cell–cell communication, epithelial transport of fluid and electrolytes are described.

The authors form a distinguished cast. Among them are people who figured prominently in the early development of membrane biology between 1930 and 1960, as well as others who are known for their work of the past 20 years. This breadth of perspective is quite unusual in contemporary books. Davson's article extends back into the middle of the 1800s to describe the first experimental evidence for the existence of membranes in plant cells, but then moves through to the mid-twentieth century and ideas about facilitated diffusion of ions across membranes.

Perhaps as a means of breathing life into an otherwise factual and rather dry history, the contributors were invited to give an anecdotal account of their roles in the scientific developments, including an impression of the personalities who influenced their work. It is this that gives the book its unusual flavour, although not all of the authors have used the device to its full effect. Lowenstein's charming account of his work on cell–cell communication is a model of the genre, full of anecdote and personal observation, and giving a real feel of the excitement that follows a chance but crucial observation. Similarly, the article by Solomon on the practical difficulties of pre-war science is not only easy to read but gives a good impression of the 'heroic' nature of the research before the industrial production of scientific instruments got underway after the Second World War (his first task was to build a cyclotron for the production of radioisotopes!). Robertson's highly personal account of his work in the early days of the electron microscope and the unit-membrane concept is also enjoyable, especially as it relates to more recent concepts of ultrastructure. It is, though, twice the length of any other contribution and as such is tiresomely long.

Some of the other articles are disappointingly bland, giving more straightforward treatments of the progression of ideas with little personal embellishment save recording of the appearance or disappearance of colleagues as the story progresses. As a result they resemble rather too closely the review articles found in contemporary multi-authored series.

Membrane Transport will provide good reading for postgraduate students and researchers who like to place the names that they frequently meet in the research literature into historical context. But the book also provides much that is of more than passing interest to those who make a career out of science. For example, there are numerous snippets of information and advice about working and publishing in a competitive scientific environment, advice which younger scientists should read with care. In addition, the recognition by more than one author that chance encounters and observations have played a large part in their achievements is cheering. But the most sobering notion is that provided by Danielli (quoted in Davson) in respect of the inevitability of scientific discovery. Having observed that the lipid bilayer was independently discovered at least three times, he concludes that "No scientist can afford to be arrogant about the degree of originality he achieves". Amen. □

Electroporate bacteria: up to 10^{10} transformants/μg!*

The Gene Pulser® apparatus and the new Pulse Controller accessory deliver high voltage pulses which permeabilize or "electroporate" intact bacteria for high efficiency transformation. Transformation efficiencies of up to 10^{10} have been obtained with *E. coli* using the Gene Pulser apparatus and Pulse Controller.[1]

Both gram negative and gram positive organisms can be electro-transformed with the Gene Pulser apparatus and Pulse Controller. Now you can go beyond the limits of conventional chemical methods. Here are just some of the bacteria electroporated with the Gene Pulser apparatus:

Haemophilus pleuropneumoniae
Bordetella pertussis
Campylobacter jejuni
Campylobacter coli
E. coli (many strains)
Klebsiella pneumoniae
Listeria monocytogenes
Lactobacillus casei
Streptococcus (many species)
Myxococcus xanthus
Rhizobium meliloti
Bacillus subtilis

The Gene Pulser apparatus and Pulse Controller offer exceptional flexibility for optimizing electrotransformation of gram positive and gram negative bacteria. Pulses of field strengths up to 12.5 kv/cm with RC time constants from 0.1 to 25 msec may be generated in the Gene Pulser cuvette with 0.2 cm electrode gap.

Both voltage and time constant are automatically measured and displayed—standard features found only on the Gene Pulser apparatus. Keep up with the rapidly expanding technology of prokaryotic and eukaryotic cell electroporation. Call Bio-Rad Technical Services at 800-4-BIORAD for more information.

Answers.

How the ear's works work

A. J. Hudspeth

The senses of hearing and equilibrium depend on sensory receptors called hair cells which can detect motions of atomic dimensions and respond more than 100,000 times a second. Biophysical studies suggest that mechanical forces control the opening and closing of transduction channels by acting through elastic components in each hair cell's mechanoreceptive hair bundle. Other ion channels, as well as the mechanical and hydrodynamic properties of hair bundles, tune individual hair cells to particular frequencies of stimulation.

THE internal ear is an evolutionary triumph of miniaturization, a three-dimensional inertial-guidance system and an acoustical amplifier and frequency analyser compacted into the volume of a child's marble. That we are ordinarily oblivious to what goes on within the labyrinth reflects the ear's reliable performance: our bipedal stance, our capacity for locomotion on foot and in vehicles and our ability to communicate vocally, all stem for the ear's incessant activity. The internal ear, in turn, owes its success to its complement of hair cells, the epithelial receptors responsible in the cochlea for our sensitivity to sound, in the utriculus and sacculus for our perception of linear accelerations, and in the three semicircular canals for our appreciation of rotatory accelerations.

The evolutionary success of hair cells is advertised by the persistence of structurally similar internal ears in all vertebrates. The volume of the human nervous system devoted to the auditory and vestibular systems also testifies to the ear's importance. The 32,000 hair cells of the two cochleae[1] and the total of 134,000 cells found bilaterally in the organs of equilibrium[2] forward their signals to the large cochlear and vestibular nuclear complexes of the brainstem's medulla and pons. The cochlear nuclei initiate a complex network of rostral projections through the pons, midbrain and thalamus to the cerebral cortex; the vestibular nuclei send information particularly to the cerebellum, oculomotor system and spinal cord.

The paucity of hair cells also accounts for the exceptional vulnerability of the auditory system. The loss of 166,000 contiguous photoreceptors in a retina would produce a scotoma smaller than the moon's image (and smaller than the blind spot that is already insensibly present). But destruction of 166,000 hair cells would entail disequilibrium and profound deafness, both major impairments. Society is awakening only slowly to the cost of acoustic trauma in both industrial and recreational settings; within the next decade or two, the 'walkman generation' will find itself unexpectedly and ardently interested in auditory pathophysiology.

Hair cells have been the subject of extensive experimentation, particularly during the past 15 years. Techniques have been developed for removing receptor organs from the ears of experimental animals and for maintaining them under microscopic observation in media of defined composition. By mechanically stimulating individual hair cells and recording the resulting electrical responses, researchers have begun to explore the cellular basis of the operation of the ear[3,4]. Here I shall review the

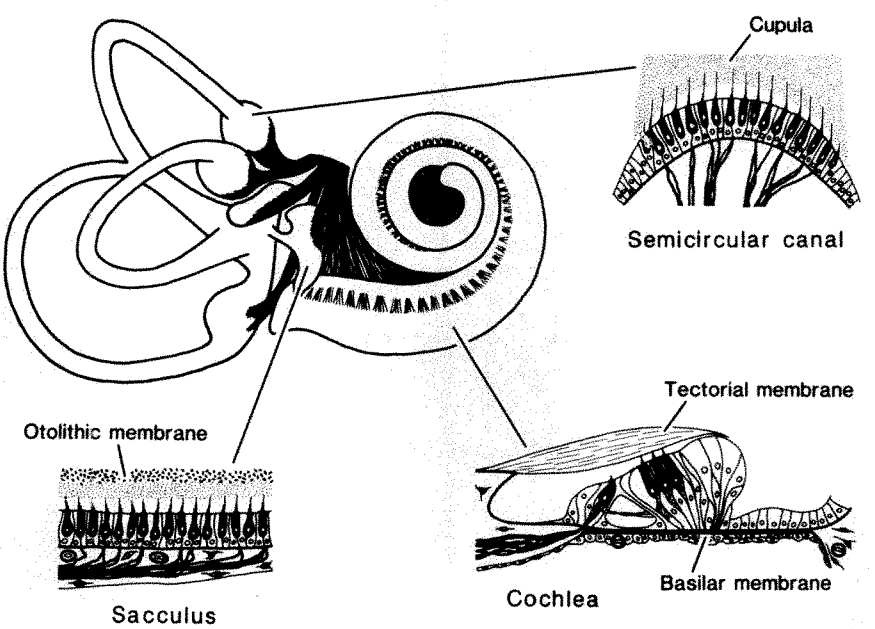

FIG. 1 Schematic diagram of the right human internal ear from an anterolateral perspective (after ref. 1). Lodged in a cavity of the temporal bone, this membranous labyrinth is immersed in perilymph, which has an ionic composition resembling that of other extracellular fluids. The inner aspect of the labyrinth is lined by a continuous epithelium that secretes and confines the Na^+- and Ca^{2+}-poor, K^+-rich endolymph which bathes the receptive surfaces of hair cells. Myelinated nerve fibres, which carry afferent information from the internal ear into the brainstem and efferent information in the opposite direction, converge to form the eighth cranial nerve. Hair cells (darkened for emphasis) occur in different arrays characteristic of the three types of receptor organs. The three semicircular canals are sensitive to angular accelerations about mutually perpendicular axes. Each consists of a toroidal, endolymph-filled cavity interrupted by a septum, the gelatinous cupula. Angular acceleration causes motion of the endolymph with respect to a canal's walls; the displaced fluid deflects the cupula and thus the hair bundles inserted into it. In the cochlea, four rows of hair cells spiral along the elastic basilar membrane in the narrow, 35-mm-long[7,8] organ of Corti. Airborne sound sets the eardrum into motion, which is conveyed to the cochlea by the bones of the middle ear. The piston-like motion of the last of these bones displaces the contents of the cochlea's three, fluid-filled internal compartments, thereby flexing the basilar membrane up and down. Hair bundles in the organ of Corti are then stimulated by the shearing motion between the apical hair-cell surfaces and the overlying, gelatinous tectorial membrane. The otolithic organs, the sacculus and adjacent utriculus, are sensitive to linear acceleration in vertical and horizontal planes, respectively. The hair cells of each organ occur in a small plaque, or macula; their hair bundles are attached to a gelatinous otolithic membrane upon which lie numerous calcareous otoconia. An acceleration, such as that due to gravity, deflects the dense otoconial mass, then the otolithic membrane and finally the hair bundles.

elegant and subtle ways in which these cells contribute to the functions of the ear, and discuss those of the hair cell's activities that we do not yet understand.

Structure of the hair cell

A human internal ear comprises six separate receptor organs, each sensitive to a particular modality and orientation of stimulation (Fig. 1). Despite this complexity, the hair cells that serve as receptors are of similar form and function in every organ. Each hair cell acts as a biological strain gauge—mechanical stimulation opens ion channels in the cell membrane. The consequent influx of current through these channels alters the membrane potential, which in turn affects the rate of release from the hair cell of a synaptic transmitter. Excited by this chemical, an afferent nerve fibre contacting the basolateral surface of the hair cell transmits to the brain a pattern of action potentials that encodes such features of the stimulus as its intensity, time course and frequency.

From the flattened apical surface of a hair cell projects its hair bundle (Fig. 2), the antenna for reception of mechanical stimuli. This organelle is a cluster of 20–300 cylindrical processes, the stereocilia, each consisting of an actin cytoskeleton[5–7] ensheathed by a tube of plasma membrane. The stereocilia are hexagonally packed and vary continuously in length across the apical surface of a hair cell; the increment in height between successive ranks of stereocilia is generally constant. A bundle is, therefore, a mirror-symmetrical, bevelled structure shaped like the tip of a hypodermic needle. A single, axonemal cilium, the kinocilium, occurs at the tall extreme of the bundle. The role of this process is uncertain, for it degenerates in the hair bundles of cells sensitive to high frequencies, and transduction persists after its microsurgical ablation[8].

Within the cytoskeleton of a stereocilium, adjacent actin filaments are extensively cross-linked by fimbrin[9,10], which holds contiguous filaments in longitudinal register and separates them laterally by 10 nm with either exact hexagonal symmetry or a less constrained, liquid-like order[6,7]. Cross-linking renders a sterocilium much more rigid than would be expected for a bundle of actin filaments free to move with respect to one another[11–13].

Isodiametric from its distal tip, along most of its length, an individual stereocilium tapers for the micrometre or so above its basal insertion. As the stereociliary diameter diminishes from 100–900 nm (refs 14, 15) to 100 nm or less, the actin filaments decrease from as many as 3,000 to about 20 (ref. 7). These residual microfilaments form a rootlet that inserts into the cuticular plate, a thick mesh of interlinked actin filaments lying beneath the apical membrane surface. If a mechanical force is applied near the tip of a stereocilium and at a right angle to its long axis, the process consequently does not flex, but pivots at its attenuated base[16]. When the hair bundle as a whole is deflected by such a stimulus, the constituent stereocilia move in unison, pivoting at their bases and sliding along one anothers' shafts. Consonant with this mode of motion, the stiffness of a hair bundle (about 1 mN m^{-1}) is roughly that expected from flexion of the actin cables at the bases of the several stereocilia[12,13,17]. The stereocilia are not wholly independent of one another, however, for they are interconnected by filamentous linkages, which may account for a bundle being somewhat stiffer along its axis of mirror symmetry than at a right angle to that axis[18].

The hair bundle is among the most elaborate and precisely specified structures in any cell: at a specific position along the basilar membrane, and at a particular location across this membrane, each hair cell has a constant number of stereocilia of fixed length and diameter, disposed in an invariant array[19]. Electron microscopice observations indicate that this precision results from a morphogenetic program of temporally separate steps[20]. Rudimentary protrusions initially stud the apical surface of a developing hair cell; beginning with those near the kinocilium, successive ranks of processes then begin to lengthen at increasing intervals. Because all the nascent stereocilia grow at similar rates after elongation commences, the delays in the initiation of growth of successive ranks of stereocilia establish the bundle's bevelled top aspect. While longitudinal growth pauses, individual stereocilia next increase in girth by the circumferential addition of actin filaments about those initially present[21]. After they have achieved their final diameters, the stereocilia resume elongation; the subsequent arrest of growth then fixes a given bundle's definitive proportions. These dimensions vary[19], for bundles cease elongation in a wave that runs up the length of the basilar papilla, leaving hair bundles at the base of the organ much shorter than those at the apex. At least in some internal ears, the height of a hair bundle is a major determinant of characteristic frequency, the stimulus frequency at which a given hair cell is most sensitive[22,23]. As a result of the sequential morphogenetic events in the internal ear, a temporal gradient in hair-bundle growth, translated into a gradient in bundle height, ultimately establishes a gradient in frequency selectivity.

Our present understanding of the structure and development of the hair bundle raises many fascinating questions. How, for example, are the dimensions of bundles specified? Despite their varied dimensions, each of the hair bundles in the chick's basilar papilla possesses a total length of 0.1 m of actin filaments[24]; does the bundle's developmental programme rely on a constant amount of starting material? Why are hair bundles so vulnerable? Although lower vertebrates add hair cells throughout life, and the cells can be mitotically replaced in such animals and in birds[25,26], no hair cell has yet been shown to be capable of regenerating its hair bundle. Perhaps the precisely choreographed steps of bundle morphogenesis cannot be repeated in mature hair cells, so that damage due to ageing, acoustical trauma and ototoxicity leads, inevitably, to a decline in our

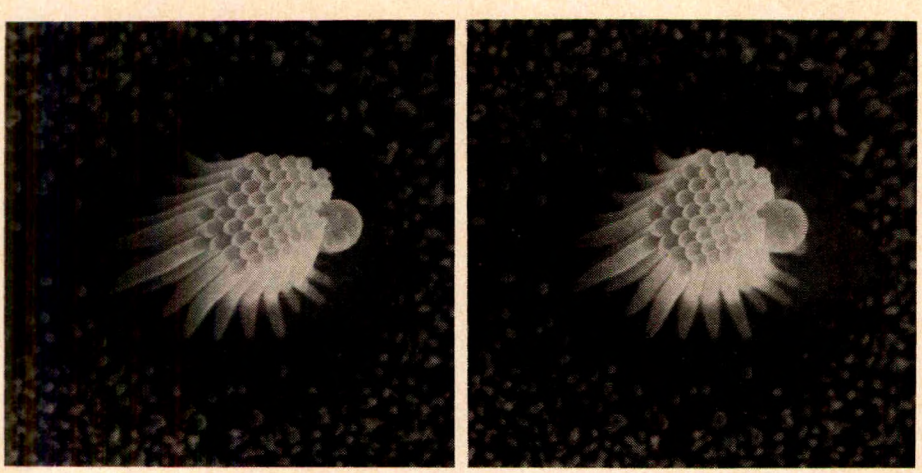

FIG. 2 A hair bundle of the bullfrog sacculus extends from the circular apical surface of a hair cell and comprises about 50 stereocilia and a single kinocilium with a bulbous termination. Magnification, ×9,000. Gradation in stereociliary lengths, from 3 μm at the bundle's left edge to 7 μm at the right, confers a plane of mirror symmetry on the structure. Deflexion of the bundle's tip in the positive direction (to the right) is excitatory, whereas stimulation in the negative direction (to the left) is inhibitory. Fixation and critical-point drying of the specimen reduced the diameters of the stereocilia and caused bowing of their basal insertions, which is not observed in living cells[113]. This stereo-pair scanning electron micrograph is meant to be viewed with divergent visual axes.

hearing capacity. How, then, are structural elements within the bundle renewed? Although it is implausible that individual actin monomers endure for a human lifetime, it is almost as difficult to see how they are replaced. Do new monomers substitute for exhausted ones by nick substitution, with re-annealing of the filament on both sides? Do new actin filaments grow alongside the existing ones, which somehow whither away? Or are whole stereocilia replaced, for example by addition of immature ones at the short edge of the bundle and progressive migration across the cellular surface to a subduction zone near the kinocilium?

Mechanoelectrical transduction by hair cells

Mechanical stimuli applied to a hair bundle elicit electrical responses by regulating, or gating, the opening and closing of mechanically sensitive transduction channels[34]. When a bundle is deflected by a probe attached at its tip (Fig. 3; ref. 27), the hair cell's response depends upon the direction and magnitude of the simulus[28-31]. In an unstimulated cell, 15% of the transduction channels are already open; the resting potential of such a cell, about −60 mV, is therefore determined in part by the inward flow of the transduction current. A positive stimulus, which displaces the bundle towards its tall edge, opens additional channels; the influx of cations depolarizes the cell by as much as tens of millivolts. A contrary stimulus, towards the short edge of the bundle, shuts those transduction channels open at rest and hyperpolarizes the cell. Stimuli at right angles to the bundle's axis of mirror symmetry, however, produce no change from the resting potential[28]. Hair cells respond only to stimulus components parallel to the axis of morphological symmetry; an oblique stimulus accordingly elicits a response proportional to its vectorial projection along that axis.

The relation between a bundle's deflexion and the ensuing electrical response is in every instance sigmoidal (Fig. 4, refs 27-32). Although displacement-response relations vary in detail from cell to cell and from species to species, a consistent and striking feature is their steepness: about 90% of the response range corresponds to a deflexion of the bundle by only 50–120 nm at its tip, or through an angle of about ±1°. In ordinary use, therefore, a hair bundle probably moves by less than the diameter of a single constituent sterocilium.

The threshold of hearing occurs at a sinusoidal hair-bundle deflexion near ±0.3 nm (refs 12 and 33); this motion of ±0.003 ° corresponds to a displacement of the pinnacle of the Eiffel Tower by only a thumb's breadth. Threshold stimulation evokes a receptor potential of ~100 μV (ref. 12), which evidently suffices for reliable synaptic transmission. From the stiffness of the hair bundle it is possible to calculate that free-standing bundles should exhibit brownian motion with a root-mean-square amplitude of 2 nm; interferometric observation confirms this inference[34]. Although the auditory system is capable of improving its signal-to-noise ratio to some extent by averaging responses over several cycles, the sensitivity of our hearing is ultimately limited because fainter sounds are drowned out by the thermal clatter of the components of the ear[35,36].

Although they have not been identified biochemically, the mechanoelectrical transduction channels of hair cells have been characterized by biophysical experiments. Pulses of transduction current observed in hair cells of the chick[37] may represent the opening of individual channels; if so, the single-channel conductance is 50 pS. Variance analysis indicates a conductance less than half as large in the hair cells of the frog[38]. Transduction channels are relatively non-selective cation-passing pores[39,40], but K^+, the ion present at the highest concentration in the endolymph around the hair bundle, normally carries most of the transduction current. Because small organic cations can support measurable current, the pore of the transduction channel must be at least 0.7 nm in diameter[39]. Divalent cations exhibit a high permeability in this channel[40]; the fact that Ca^{2+} traverses the channel less efficiently than K^+ (ref. 39) suggests that divalent ions have such a high affinity for the pore that they linger there several times longer[3]. Aminoglycoside antibiotics, whose most deleterious side effect is ototoxicity exerted against hair cells, also enter and obstruct the channels[40,41].

Transduction channels are few in number. The steps in transduction current observed in chick hair cells, assuming they result from the opening of individual channels, suggest that these cells have under 20 channels apiece[37,40]. Analysis of the variance in transduction current[38], as well as measurement of the forces involved in channel gating[32], indicates that a hair cell from the bullfrog's sacculus has 50–100 channels. Because there are a comparable number of stereocilia in the hair bundle of such a cell, and as the magnitude of the response is roughly proportional to the number of stereocilia remaining in a microdissected bundle[8], there may be only one active transduction channel per stereocilium. Together with the absence of high-affinity ligands with which to label the channels, this scarcity of channels accounts for the dearth of biochemical information about them.

Mechanoelectrical transduction channels

What, then, opens mechanoelectrical transduction channels? Although displacement *per se* may be measured with devices ranging from yardsticks to interferometers, the usual practice in engineering is to infer the magnitude of a displacement indirectly by detecting the strain that a force produces in some elastic material. A hair cell's sensitivity is ordinarily measured in terms of hair-bundle displacement, but there are several indications that mechanoelectrical transduction in fact involves a biological strain gauge. The bundle seems to contain elements, the gating springs, the tension of which controls the opening and closing of transduction channels.

First, in measurements of stiffness of a hair bundle, it is possible to detect a component that is associated with mechanoelectrical transduction. A bundle is stiffer along its axis of morphological symmetry than at a right angle; the extra stiffness, moreover, declines as a cell adapts to a protracted mechanical stimulus[18]. The evidence suggests that a portion of the work done in deflecting a bundle goes into the gating springs. These springs collectively contribute ~50% of the stiffness that opposes the bundle's flexion[18,32]; as a result, the transducer efficiently harvests the energy supplied when the bundle is stimulated.

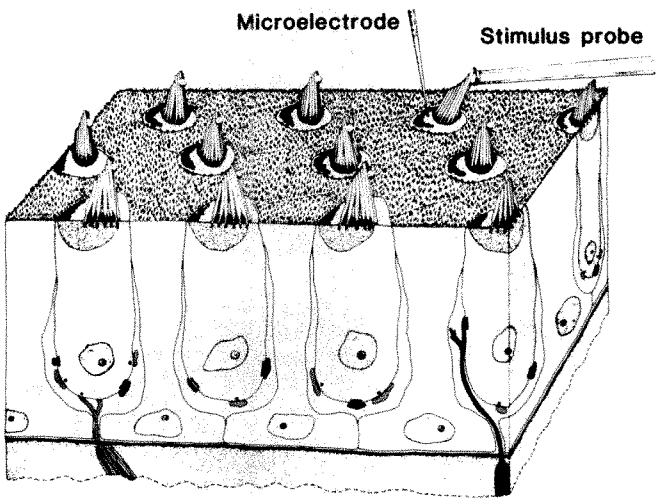

FIG. 3 Experimental procedure for recording electrical responses from a hair cell *in vitro*[27]. Hair cells from the bullfrog sacculus lie in an epithelial sheet, separated by supporting cells with apices covered by microvilli. Afferent and efferent synapses stud the hair cells' basolateral surfaces. A microelectrode is used to measure the cell's receptor potential or, under voltage-clamp conditions, its transduction current. A glass probe applied to the hair bundle's distal end enables the experimenter to provide a mechanical stimulus of any desired orientation, amplitude and waveform. For measurements of bundle stiffness, the stimulus probe is replaced by a flexible glass fibre positioned at a right angle to the probe illustrated here.

The time course of channel gating provides a second line of evidence for gating springs. The response latency is so brief—in the order of microseconds—that gating is probably direct, rather than operating through a second messenger[42]. Moreover, larger step stimuli elicit electrical responses that (up to a saturating level) are not only larger, but also rise faster[31,43]. This behaviour favours a kinetic scheme in which mechanical force controls the rate constants for channel gating. If the mechanical energy from a stimulus were stored in a spring attached to the channel's gate, the rates of channel opening and closing would be determined by the probability that the energy content of the spring exceeds the transition-state energy for channel opening or closing. Because stimuli primarily affect the opening rate constant[31,43], the rate-limiting, transition-state configuration of the transduction channel probably resembles the open state[3].

The third line of evidence for gating springs can be introduced through a homely analogy. Imagine tying an elastic cord to the knob of a closed door, then measuring the cord's stiffness by applying a known force at its free end and measuring its consequent extension. A similar estimate of the stiffness would result if the door were instead held wide open. Suppose, however, that the experiment were repeated with the door initially closed, but free to open. As one exerted the usual force on the cord, its free end would move further as the door swung open, in the direction of the force. The experimenter might conclude that the cord is less stiff over the range of displacements in which the door opens.

The hair bundle exhibits such an effect: the bundle is ~40% more flexible near its resting position than at the extremes of positive or negative displacement (Fig. 4; refs 32 and 44). Three lines of evidence associate this augmented compliance with the gating of transduction channels: the range of bundle displacements over which the compliance increases coincides with that over which channels open and close; the compliance is blocked by aminoglycoside drugs that obstruct transduction channels; and the bundle's position of enhanced compliance comigrates during adaptation with the position of mechanosensitivity. Quantitative analysis of the gating compliance confirms that there are only one to a few transduction channels per stereocilium[32]. The results also suggest that individual gating springs are about as stiff as single protein filaments. The gate of the transduction channel evidently swings through 4 nm upon opening, which is opposed by a restoring force of about 2 pN.

The existence of gating compliance implies a reciprocal interaction between the forces on the hair bundle and the gating of transduction channels. Not only does force applied to the bundle influence the probability of a channel being open, but the channel's status affects the force exerted by the bundle. This observation therefore buttresses the argument that transduction channels are mechanically gated by elastic elements: if a second messenger intervened in the transduction process between the force-sensitive apparatus and the ion channel, gating compliance would not be expected. Along with the responses of motor proteins, gating compliance constitutes one of the few mechanically measured signals of a molecular conformational change of the sort invoked to explain the activities of enzymes and ion channels.

What, and where, are the gating springs?

Despite the evidence that stimulus forces are directly communicated to transduction channels by gating springs, the identity of these elements remains uncertain. Gating springs might, for example, be cytoskeletal components of the hair bundle or integral parts of the transduction-channel molecules themselves. The plasma membrane is also an appropriately elastic structure that might constitute a gating spring, in which case transduction channels could prove to be stretch-activated[45]. Lacking a histochemical or other morphological marker for the transduction channels, we must infer the location of the gating springs from indirect evidence. Unfortunately, the two relevant physiological experiments to date provide seemingly contradictory results.

From the polarities of extracellularly and intracellularly recorded responses, we know that the cationic current that enters a hair cell through transduction channels must cross the apical plasma membrane[46], which includes the membrane covering the stereocilia and kinocilium, as well as that on the flattened cellular surface. To reach the apical membrane, the current flows through the saline solution around the bundle; in so doing, it must inevitably produce a tiny potential drop across the resistance that this medium affords. Measurement of the extracellular potentials about a stimulated hair bundle points to a current sink at the top of the bundle, near the tips of the stereocilia (Fig. 5; ref. 47). The signals are of the magnitude anticipated from the size of the transduction current and the resistivity of the medium. The responses also display the expected sensitivities to membrane potential, to an ototoxic antibiotic, and to the direction and amplitude of stimulation.

The current-sink experiment provides evidence that transduction channels lie near the tips of stereocilia. This interpretation, however, rests on the presumption that the extracellular flow of current toward the transduction channels is not severely distorted by the presence of the hair bundle. This assumption seems reasonable because electron microscopy indicates that about half of the volume within a bundle is extracellular space to which large proteinaceous markers have access (R. A. Jacobs and A. J. H., unpublished observation) and through which ionic current should readily flow.

Transduction current entering channels near the stereociliary tips would have to flow axially down the stereocilia before it could effect a change in the membrane potential of the soma, and hence in the release of synaptic transmitter. Unless the internal resistivity of the stereociliary interior is unusually high, however, the decrement in steady-state responses should be only a few per cent[47]. Because of current flow across the stereociliary membrane capacitance, responses to high-frequency stimulation could be more severely attenuated. Perhaps in part to counter this problem, however, the hair bundles of organs responsive to high-frequency sounds are systematically shorter than those in receptors for low-frequency stimuli[19,48,49]. To cite extreme cases, the bat's cochlear receptors for 83 kHz ultrasound have 0.8 μm stereocilia[15], whereas receptors for low-frequency angular acceleration are endowed with stereocilia over 90 μm in length[50].

An alternative method for locating transduction channels relies on the fact that these channels can pass divalent cations. On the assumption that intracellular accumulation of Ca^{2+} following mechanical stimulation reveals the site of transduction, a Ca^{2+}-sensitive fluorescent dye, fura-2, has been used to follow the appearance of Ca^{2+} in the cytoplasm of hair cells[51]. The largest fluorescence signals are observed in the apical cytoplasm,

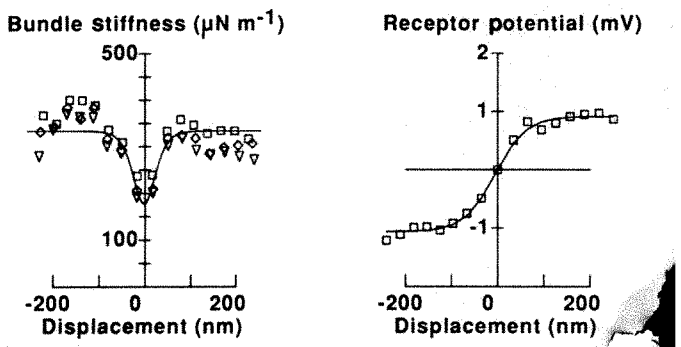

FIG. 4 Gating compliance is a reduction in the hair-bundle stiffness (left) measured by applying known forces to a bundle with a flexible glass fibre, then calculating from the fibre's flexion the stiffness of the attached bundle[44]. The fact that compliance is greatest over the range of hair-bundle positions where transduction is most sensitive (right) suggests that the compliance results from the opening and closing of transduction channels.

immediately beneath the hair bundle, suggesting that transduction channels lie at the bases of the stereocilia or in the adjacent membrane of the flattened cellular apex.

Although the Ca^{2+}-detection experiment provides a useful second method for seeking the site of transduction, the indirect nature of the measurement introduces three complications into interpretation of the data. First, because the average Ca^{2+} ion would be expected to diffuse several micrometres while bound to the dye[52,53], the results do not pinpoint the site of Ca^{2+} entry. Second, the experiment shows where Ca^{2+} accumulates after continuous stimulation for several hundred milliseconds; but as the membrane-permeable form of fura-2 is used[51], the result could reflect the gradual accumulation of Ca^{2+} in vesicular organelles around the cuticular plate[49]. Third, the thin stereocilia of a hair bundle, even when well filled with dye, provide a much weaker fluorescence signal than does the nearby soma. The published data therefore do not exclude the possibility that Ca^{2+} enters stereocilia near their tips, then diffuses to a site in the soma where it produces a more prominent optical signal than within the bundle.

Ultrastructural analysis of hair cells has failed to resolve the lingering uncertainty about the site of transduction. Although freeze-fracture studies demonstrate intramembrane particles on the apical cellular surface, there is no evidence for specializations at either the bases or the tips of stereocilia[54,55]. Scanning and transmission electron microscopy has, however, put forward a specific type of inter-stereociliary connection as a candidate to be the gating spring. This tip link is a single strand joining the distal end of almost every stereocilium to the side of the longest adjacent process (Fig. 6; refs 56–58). Not only are tip links well situated to sense hair-bundle motion, but their orientation could account for the vectorial sensitivity of transduction. Pushing a bundle in the positive direction should elongate the tip links and, if they are the gating springs, promote channel opening. Oppositely directed stimuli should slacken the links and close the channels. Stimulation at a right angle to the bundle's plane of symmetry would be expected to elicit little response, for the links invariably run in a direction parallel with that plane.

Identification of the tip links with the gating springs is alluring: the links occur in every hair bundle for which data are available, and their position at the bundle's top would accord with measurement of a transduction-current sink there. There is, nevertheless, no direct evidence that the tip links are the gating springs. It would be very desirable, for example, to confirm that the links are elongated during excitatory stimulation, shortened upon inhibitory stimulation, and unaffected by stimuli that elicit no change in the transduction current. Until such demonstrations have been accomplished, or until the tip links have been shown to be unnecessary (perhaps by being enzymatically digested while transduction survives), the hypothesis will remain only that.

Adaptation

Despite the precision with which it forms, a hair bundle is unlikely to develop so accurately that the sensitive transduction apparatus is perfectly poised at its position of greatest mechanosensitivity. Some mechanism would seem necessary to compensate for developmental irregularities, as well as for environmental changes, by resetting the gating springs to accord with the bundle's resting position[59]. An adaptation process that continuously adjusts the bundle's range of operation does just that, maintaining high sensitivity to transient stimuli while in certain hair cells rejecting static inputs a million times as large[60].

Adaptation manifests itself as a progressive decrease in the transduction current following the onset of a protracted hair-bundle deflection[61]. The application of test stimuli during the course of adaptation reveals that the process differs from desensitization: transduction persists with normal sensitivity, but the position at which the transducer is most sensitive migrates from the bundle's resting position towards that at which the bundle is held. Adaptation occurs on a timescale three orders of magnitude slower than mechanoelectrical transduction: the time constant of adaptation to a half-saturating stimulus is ~30 ms with endolymph bathing the hair bundle[61]. Both the rate and the extent of adaptation increase with increasing concentration of Ca^{2+} in the fluid contacting the apical cellular surface[61,62].

How does adaptation occur? Because the hair bundle becomes measurably less stiff as adaptation proceeds[18], the process evidently involves a reduction of the tension in the gating springs. This could come about in several ways; the cuticular plate could warp so as to adjust the interrelation of the stereocilia, for example, or the individual stereociliary cytoskeletons could change dimensions. If the tip links are the gating springs, the most likely possibility is that the anchoring points for these links are repositioned in a negative-feedback cycle (Fig. 7; ref. 63). Suppose that a gating spring is kept tense by an attached motor protein, for example a myosin I molecule similar to the protein of relative molecular mass 110,000 found in microvilli[64], crawling up a cytoskeletal actin filament. When a stimulus step increases the tension in the spring, the associated transduction channel spends a larger fraction of its time open. The increased cation influx includes Ca^{2+}, which accumulates in the stereocilium and interacts with the motor protein, decreasing its upward force. The gating spring then shortens by pulling down the motor molecule; when the spring reaches its resting tension, closure of the channel reduces the Ca^{2+} influx to its original level, restoring a balance between the upward force produced by the protein and the downward tension in the spring. In this model, Ca^{2+} would function as a second messenger in hair-cell adaptation rather as it does in the light-adaptation process of photoreceptors[65].

According to this model for adaptation[63], the diminution in stiffness of the hair bundle during adaptation would be expected as a consequence of declining tension in the gating springs[18]. Another result consistent with the model is that extensive depolarization of a cell, which would be expected to diminish the influx of Ca^{2+} through transduction channels, elicits motion of the hair bundle in the negative direction, towards its short edge[62]. This response is to be expected if the reduced influx of Ca^{2+} causes the motor protein to increase the tension in the gating springs.

Cellular contributions to frequency selectivity

Although they must contend with stimuli of very low energy content, hair cells enjoy the advantage that these inputs are often periodic in nature. If the significant part of stimulus consists of a regular signal, such as the sinusoidal pressure due to a pure-tone acoustical stimulus, a detection system can increase its signal-to-noise ratio by selectively amplifying the response to a relevant frequency. At least two mechanisms are now known that accomplish this task on a cellular level.

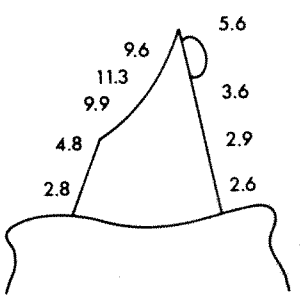

FIG. 5 Localization of the site of mechanoelectrical transduction by determination of extracellular current flow. While a hair cell is mechanically stimulated, extracellular potentials are recorded at various sites about the hair bundle[47]. Flowing through saline solution with a resistivity of 1 Ω m, a typical transduction current of 200 pA would be expected to produce signals of the observed magnitudes (shown as average peak-to-peak values in microvolts). The strong response at the bundle summit indicates that mechanoelectrical transduction occurs there, near the stereociliary tips.

The first cellular frequency filter occurs prior to mechanoelectrical transduction: the mechanical properties of each hair bundle conspire to tune it to a particular frequency. A tuning fork's resonant frequency depends upon the flexibility and mass of its tines; in a similar way, the natural frequency of a hair bundle depends upon its mechanical properties. The elastic elements that restore a bundle to its upright, resting position include—and are probably dominated by—the actin cables at the bases of the stereocilia[12,13]. Because the bundle moves through an aqueous medium of comparable density, the relevant mass in the bundle's tuning includes that of a volume of water viscously dragged along by the moving bundle[66]. Viscosity also heavily damps the motion: although a bundle responds optimally at a particular frequency, it differs from a tuning fork in being incapable of sustained oscillation after stimulation has ceased.

As noted above, the hair bundles of many auditory organs display a gradation in length along the frequency axis. In line with the tuning-fork mechanism of frequency selectivity, the bundles are relatively long on hair cells that respond to low-frequency acoustical, vibrational and accelerational stimuli[50], whereas the shortest bundles occur on receptors for the highest-frequency acoustic signals[15]. The stiffnesses of hair bundles are also inversely related to their lengths[17].

The motion of hair bundles is difficult to simulate for several reasons: bundles are of a complex shape, have many internal degrees of mechanical freedom, occur at the surface between a fluid and a solid, and lie close enough together that their movements are influenced by those of their neighbours. Despite this hydrodynamic complexity, computer modelling[66,67] shows that the tuning-fork mechanism can account for the observed frequency selectivity of cells with free-standing hair bundles[22,23], which are not attached to a tectorial membrane. Stereociliary length may also affect the tuning of cells whose hair bundles are inserted into a tectorial membrane[68], for these cells too exhibit an inverse relation between bundle length and characteristic frequency[48,49].

The second mechanism that tunes individual hair cells to specific frequencies is electrical in nature[69], and, in contrast to mechanical tuning, occurs subsequent to mechanoelectrical transduction. The membrane properties of certain hair cells in amphibians[70], reptiles[71] and birds[72] are such that the membrane potential tends to resonate at a particular frequency. This characteristic is demonstrated by injecting a pulse of current into a hair cell, whereupon the membrane potential undergoes an exponentially damped, sinusoidal oscillation[71]. When such a cell is stimulated with mechanical stimuli of constant amplitude, its transduction apparatus responds over a broad range of frequencies. Stimulation at the particular frequency at which a cell's membrane potential resonates when current is injected, however, evokes the largest receptor potential. Because the release of synaptic transmitter at the basolateral surface of the cell is controlled by membrane potential, the postsynaptic nerve fibres innervating the cell are most responsive to stimuli of the specific frequency[73].

The origin of electrical resonance has been determined by recordings from enzymatically isolated hair cells with the whole-cell and patch variants of the tight-seal electrode technique[74,75]. Current carried into a hair cell through voltage-sensitive Ca^{2+} channels drives the depolarizing phase of an oscillation; the hyperpolarizing component results from current through Ca^{2+}-sensitive K^+ channels[70]. Several factors establish such features of the resonance as its frequency and damping: the membrane capacitance, the numbers and kinetic properties of the Ca^{2+} and K^+ channels and the time course of Ca^{2+} removal from the membrane by diffusion, sequestration and extrusion[74,76,77].

It remains to be determined how hair cells become tuned to their appropriate frequencies[69,77]. In the basilar papillae of reptiles and birds, for example, there is a continuous representation of best frequencies from one end of the organ to the other. Some of the systematic variation in oscillation frequency accrues from differences in the gating kinetics of K^+ channels[74]. Do these channels occur in several isoforms that are appropriately doled out to cells, or are channels of one or a few sorts post-translationally modified to adjust their kinetic properties? The behaviour of K^+ channels might instead be dominated by factors that control the rate of disappearance of Ca^{2+} from beneath the membrane, in which case the regulation of Ca^{2+} homeostasis will prove of primary importance in the establishment of tuning.

Cochlear frequency selectivity and force production

In the mammalian cochlea, pure-tone stimulation evokes travelling waves that propagate from the base of the basilar membrane towards its apex, peaking in amplitude at a specific point along the way[78]. Each position along the basilar membrane is most sensitive to a particular frequency of stimulation; the characteristic frequencies are arranged in a monotonic order along the membrane, with high frequencies mapped to the cochlea's base, low frequencies to its apex. The sharpness of frequency discrimination is similar, whether measured in terms of basilar-membrane motion[33,79], hair-cell response[80], or eighth-nerve activity[81]. Complex acoustic stimuli, which can be resolved into multiple sinusoidal components, evoke a basilar-membrane disturbance that is (at least approximately) the superposition of the membrane's response to the constituent tones: the basilar membrane acts as a frequency analyser that apportions stimulus energy to the hair cells arrayed along its length according to a sound's content of various pure tones.

The tuning observed in the cochlea appears too sharp to result solely from the passive hydrodynamic and mechanical properties of the basilar membrane. Frequency selectivity might be enhanced through mechanical resonance by the tectorial membrane[82], the gelatinous mass into which the hair-bundle tips of outer hair cells are inserted. Another possibility is that tuning is sharpened by force-producing elements that counter the damping effects of the cochlear fluids[83–85]. The strongest evidence for such an active process is that cochleae can emit sounds, both spontaneously[86] and in response to acoustic stimulation[87] at frequencies as high as 62 kHz (ref. 88). Because the sound that spontaneously emerges from ears has an energy and statistical properties that cannot be explained by narrow-band

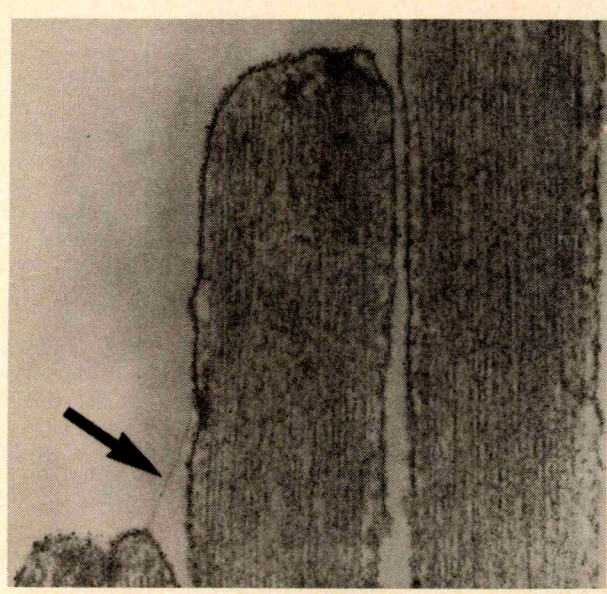

FIG. 6 A tip link, shown here in an electron micrograph of a hair cell from the bullfrog sacculus, is a thin fibre (arrow) that connects the end of one stereocilium to the side of the next. Magnification, ×115,000. Such a link may be the gating spring that opens a transduction channel at one end or the other (or both). Evenly spaced actin filaments form the cytoskeletons of the stereocilia.

filtering of noise from within an animal[89], one must conclude that something in the ear actively moves, liberating energy in the form of mechanical vibrations.

What supplies this energy? Several lines of evidence implicate the outer hair cells of the mammalian cochlea as the elements that enhance frequency selectivity, and hence as the energy sources. These cells, which spiral in three rows alongside the single row of inner hair cells, make only token projections to the central nervous system through their afferent fibres. They receive a copious efferent innervation[90], however, whose activation decreases both cochlear sensitivity and frequency discrimination[91]. Pharmacological ablation of outer hair cells affects responsiveness even more profoundly[92].

An isolated outer hair cell can display motility *in vitro*[93,94]: when stimulated electrically, it shortens when depolarized, elongates when hyperpolarized[95,96]. The energy for the effect could be derived from the experimentally imposed electrical field, rather than from hydrolysis of an energy-rich substrate[4,96,97]. Consistent with this, such a cell displays a component of capacitive current that reflects the motion of voltage-sensitive molecules in the cell membrane[97]; these moving molecules might distort the elastic cytoskeleton[98].

Despite the demonstrations that outer hair cells can shorten, several reasons remain for scepticism that such contraction constitutes the motor for cochlear tuning and emission. First, because outer hair cells are orientated nearly perpendicular to the basilar membrane in some cochleae, including those of humans[1], changes in the cells' length would be expected to apply forces principally along hair bundles, rather than at a right angle, along the bundles' axes of mechanosensitivity. For that reason, the motion relevant to tuning might prove to be tipping of the hair cells' apical ends[99]. Second, motility based upon voltage-sensitive membrane components should suffer attenuation at high frequencies because of the membrane's capacitance. The outer hair cell's membrane time constant of 0.13–3 ms (refs 100, 101) corresponds to a corner frequency between 50 Hz and 1.3 kHz. Although voltage-driven mechanical responses could occur at higher frequencies, they would become progressively less efficient. Third, because hydrodynamic drag is proportional to the velocity of a moving object, the energetic cost of cell-body motion would rise with increasing frequency. Fourth, the electromechanical gain of isolated outer hair cells, 2 $\mu m\ V^{-1}$ (ref. 101) at the resting potential of −70 mV (ref. 100), seems too small for motility to exert a significant effect on transduction in response to receptor potentials near threshold[101]. Finally, acoustic emissions are not confined to the mammalian cochlea, the sole domain of morphologically specialized outer hair cells; evoked emissions occur in birds[102] and spontaneous emission even in amphibians[103,104]. The energy-producing process, like other features of mechanoelectrical transduction, seems to be common to hair cells throughout the vertebrates. It remains possible, for example, that all hair cells can display the shortening response under appropriate conditions.

Another site of force production that might contribute to frequency tuning is the hair bundle, which may prove to be more than a recipient of stimuli. In addition to displaying passive elasticity, some bundles are capable of actively exerting forces against other objects. The bundles of electrically resonant hair cells display back-and-forth motion in phase with the electrical signals; a bundle moves in the positive direction as the membrane depolarizes[12,18]. In addition, following displacement in the positive direction by a flexible fibre, a bundle can transiently push back against the probe, producing a rebound motion[18,32]. There are no data on the mechanism of force production by hair bundles, nor is there evidence that bundles can generate forces at the very high frequencies at which sharp frequency selectivity and acoustic emission are observed.

Why is transduction direct?

In contrast to hair cells, many other sensory-receptor cells—vertebrate photoreceptors[105] and olfactory neurons[106], for example—employ cyclic nucleotides or other second messengers in transduction. Two advantages stem from this strategy: the enzymatic apparatus that generates a second messenger provides amplification, and feedback within the metabolic pathway permits gain control such as adaptation or desensitization.

What is the selective advantage of transduction without the intervention of a second messenger? The answer probably lies in the speed of response; hair cells operate much more quickly than do other sensory-receptor cells of the vertebrate nervous system, and indeed, faster than neurons themselves. Transduction by hair cells must be rapid to deal with the frequencies of biologically relevant stimuli. The behaviour of sound in air and the physical dimensions of animals, particularly those of sound-emitting and -absorbing organs such as vocal cords and eardrums, make frequencies in the kilohertz range optimal for auditory communication. Much lower frequencies are inefficiently captured by animals of moderate size; much higher frequencies propagate poorly through air.

The localization of sound sources, one of the most important roles of hearing, sets even more stringent limits on the speed of transduction. If a sound source lies directly to one side of an animal, an emitted sound will reach the nearer ear somewhat sooner than the farther; for a human, this maximal delay is about 700 μs (ref. 107). Both humans[108] and owls[109] can locate sound sources on the basis of much smaller temporal delays, less than 20 μs. For this to occur, hair cells must be capable of detecting acoustical waveforms with microsecond-level resol-

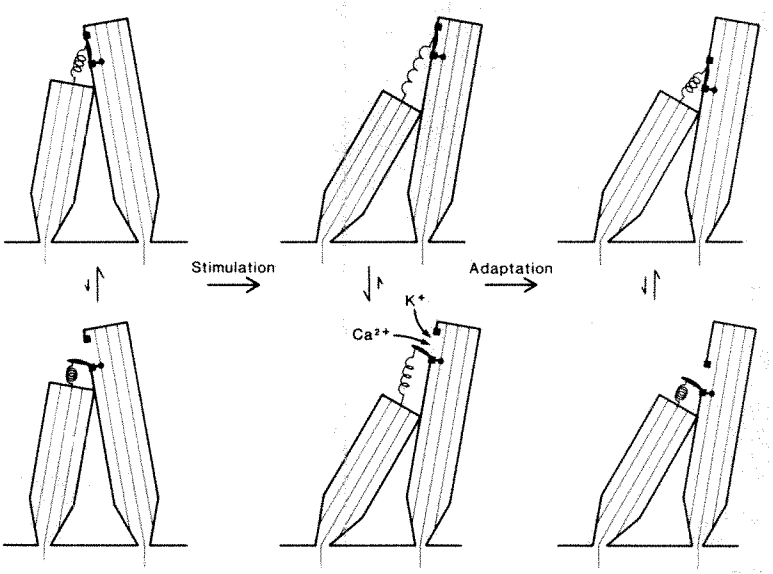

FIG. 7 A model for transduction and adaptation by hair cells[63]. Each stereocilium has near its tip a transduction channel attached to a gating spring. When the bundle is in its resting position (left), the channel rattles between its closed (upper) and open (lower) configurations about one thousand times per second; as suggested by the relative sizes of the reaction-rate arrows, however, the channel is shut most of the time. Immediately after a positive stimulus is applied (centre), shear between the stereocilia increases tension in the gating spring and promotes channel opening; entry of cations such as K^+ and Ca^{2+} then depolarizes the cell. As adaptation occurs during a few tens of milliseconds (right), repositioning of the gating spring's end, possibly by a motor protein descending the actin cytoskeleton of the stereocilium, reduces tension in the gating spring and allows channel closure.

ution; even more remarkably, this temporal information must be transmitted along axons whose individual signalling rate is less than 1 kHz. The unusual innervation ratio of the mammalian cochlea, with more than 20 axons innervating a single inner hair cell in some instances[90], may be required for data transmission at a suitable rate.

Active echo-location, the hunting strategy employed by some bats and whales, places extreme demands on the speed of auditory transduction. To detect potential prey, let alone to resolve surface features that are useful in its identification, a bat must emit sound with a wavelength comparable to the dimensions of the target. A 3 mm insect, for example, efficiently reflects sound only at frequencies near and above 100 kHz. Chiropterans and cetaceans, whose auditory responses extend to at least 150 kHz, exploit the direct nature of hair cell transduction to the fullest.

The responsiveness of hair cells to high frequencies of stimulation implies that transduction channels are very rapidly gated. Even in frogs sensitive to relatively low frequencies, a stimulus of moderate intensity causes a response with a time constant of only 80 μs at 24 °C. The activation enthalpy of the channel-opening reaction, about 50 kJ mol^{-1} (ref. 43), implies that such channels would open with a time constant as small as 30 μs at 37 °C. To respond to frequencies in excess of 100 kHz, mammalian hair cells might have gating rates as much as an order of magnitude faster.

The rate of gating of the mechanoelectrical transduction channel is remarkable by comparison with the pace of spontaneous rearrangement of protein molecules. A structural domain of the size expected for the transduction-channel gate probably diffuses on a timescale of approximately a millisecond[110]. There is, however, no inherent difficulty with a much faster-moving gate: breathing motions of a protein are driven by thermal energy, but channels can be gated by externally supplied energy. A sodium channel, for example, is thought to be opened when an electrical field causes sliding motions of four charged, α-helical segments of the channel protein[111]. This relaxation, which involves the relocation of about 90 amino-acid residues, can occur with a time constant of 10 μs (ref. 112). If a hair cell's transduction channel opens when a force directly displaces a gate from the ion-passing pore, the mechanical energy supplied by the stimulus can account for the channel's extraordinary—and most useful—speed of operation. □

ACKNOWLEDGEMENTS. The author thanks Drs P. G. Gillespie, A. H. Gitter, J. Howard, and L. F. A. Jaramillo for their comments on the manuscript, and colleagues at the University of California, San Francisco for a stimulating environment. Mr R. A. Jacobs fabricated the experimental apparatus, provided the electron micrographs of Figs 2 and 6, produced the figures and critically perused the manuscript. The NIH and the System Development Foundation supported the author's experimentation and the writing of this review.

"The years of anxious searching in the dark... and the final emergence into the light— only those who have experienced it can understand it."

Albert Einstein

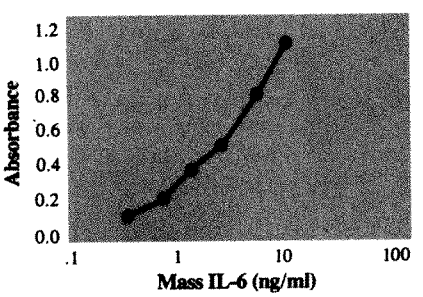
IL-6 ELISA Kit
A search made simpler.

The InterTest-6™ ELISA kit offers you a simpler method of measuring human Interleukin-6 (IL-6). For studying the role of IL-6 in the immune response, inflammation, or cancers, the InterTest-6 kit gives you everything you need and more:

Sensitivity: accurate IL-6 measurements in the range of 0.5–25 ng/ml.

Specificity: no detectable cross reaction with TNF-α, IFN-γ, IL-1, IL-2, IL-3, IL-4, G-CSF, M-CSF, or GM-CSF.

Time savings: results are ready within 24 hours—three times faster than bioassays.



Convenience: contains all necessary reagents including microtiter strip wells and easy-to-follow instructions.

InterTest-6 is the newest addition to Genzyme's innovative line of immunoassay kits for research use. And, like all of our cytokine products, it comes with technical support and our guarantee of performance. For more information or to place an order, call **1-800-332-1042** or outside the USA **1-617-876-9404.**

IL-6 Production in Cell Cultures as Determined Using InterTest-6

Cell Culture	Duration	IL-6 ng/ml
T-cell clone 1	24 hrs	<0.3
T-cell clone 2	24 hrs	1.2
Transformed T-cell line	24 hrs	21.1
Plastic Adherent Cells + LPS	8 hrs	10.6
PBMC + PHA	24 hrs	4.9
PBMC + PHA	72 hrs	16.2
PBMC + Media	72 hrs	<0.3

Typical Standard Curve Using InterTest-6

Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer.

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

Take out a personal subscription to Nature today at HALF PRICE.

APPLIED AND THEORETICAL ELECTROPHORESIS

The Official Journal of the International Electrophoresis Society

Editor in Chief Carl R. Merril, *Bethesda, MD, USA*

CONTENTS OF THE FIRST TWO ISSUES INCLUDE:

Editorial
Carl R. Merril

Differential phosphate labeling of stress protein polypeptides in toxic dose response during S-phase of mouse lymphoma cells: a micro-electrophoretic study
J.L. Pipkin, J.F. Anson, W.G. Hinson, E.R. Burns & D.A. Casciano

Differential [^{32}P]-labeling of chemically induced stress proteins in S-phase mouse lymphoma cells
James L. Pipkin, Jeanne F. Anson, William G. Hinson, E. Robert Burns & Daniel A. Casciano

A new mode of rotating gel electrophoresis for fractionating linear and circular duplex DNA: the effects of electrophoresis during the gel's rotation
Philip Serwer & Shirley J. Hayes

Synthesis of buffers for generating immobilized pH gradients. I: Acidic acrylamido buffers
Marcella Chiari, Elena Casale, Enzo Santaniello & Pier Giorgio Righetti

Synthesis of buffers for generating immobilized pH gradients. II: Basic acrylamido buffers
Marcella Chiari, Elena Casale, Enzo Santaniello & Pier Giorgio Righetti

Rehydratable agarose gels: Use of low EEO agarose without charged additives
Erich Gombocz & Andreas Chrambach

Oxidation of alkaline immobiline buffers for isoelectric focusing in immobilized pH gradients
Pier Giorgio Righetti, Marcella Chiari, Elena Casale & Claudia Chiesa

Isoelectric focusing of recombinant interferon-ß
Susan Hershenson & Jody Thomson

Computerized classification of two-dimensional gel electrophoretograms by correspondence analysis and ascendant hierarchical clustering
Thierry Pun, Denis F. Hochstrasser, Ron D. Appel, Matthieu Funk, Valérie Villars-Augsburger & Christian Pellegrini

An equation for DNA electrophoretic mobility in agarose gels
Charles E. Willis, Diana G. Willis & Gerald P. Holmquist

The mechanism of DNA's fractionation during pulsed-field agarose gel electrophoresis: a hypothesis
Philip Serwer

Improved separation of multi-locus hypervariable DNA restriction fragments by field inversion gel electrophoresis and fragment detection using a biotinylated probe
Craig Fowler, Jenny D. Skinner, Leigh A. Burgoyne & James L. McInnes

The effects of field inversion electrophoresis on small DNA fragment mobility and its relevance to DNA polymorphism research
Pablo V. Gejman, Natraj Sitaram, Wang-Ting Hsieh, Joel Gelernter & Elliot S. Gershon

'Catalysts' for polyacrylamide gel polymerization and detection of proteins by silver staining
Denis F. Hochstrasser & Carl R. Merril

Rapid scanning thermal lens laser transmission densitometer
Konan Peck, Tshenge Demana & Michael D. Morris

Mixture decomposition applied to the analysis of two-dimensional electrophoretic separation of protein samples
John Taylor & Carol S. Giometti

Thermally reversible gels in electrophoresis. I: matrix characterization
Pier Giorgio Righetti & Robert S. Snyder

Submicrogram quantities of unstained proteins are visualized on polyvinylidene difluoride membranes by transillumination
Juan A. Reig & David C. Klein

Fingerprinting of proteins cleaned in solution by cyanogen bromide
Rose N. Skopp & Leslie C. Lane

A zone electrophoretic-isoelectric focusing study on the inactivation of human Alpha 1-Antitrypsin by elastase
John S. Baumstark

HDL particle associated proteins in plasma and cerebrospinal fluid: identification and partial sequencing
Anne-Catherine Hochstrasser, Richard W. James, Brian M. Martin, Michael Harrington, Denis Hochstrasser, Daniel Pometta & Carl R. Merril

Reader Service No.19

To: Dionne Stocking, Macmillan Press Ltd., Houndmills, Basingstoke, Hants RG21 2XS, UK.

Journals from
ACADEMIC PRESS

IMPACT of Computing in Science and Engineering

Managing Editor
Peter Deuflhard
Konrad Zuse Center, Berlin, Federal Republic of Germany

IMPACT of Computing in Science and Engineering focuses on articles from the areas of mathematical and scientific modeling, scientific computing, computer science, and scientific and engineering applications. The journal is interdisciplinary in nature, with papers touching upon a combination of at least two of the four main areas. Articles typically describe real-life problems attacked by a new or specifically adapted algorithm or by any other new computing technique.

A Representative Selection of Articles

Ivo Babuška, B. Guo, and Manil Suri
Implementation of Nonhomogeneous Dirichlet Boundary Conditions in the p Version of the Finite Element Method

O. Pironneau and J. Rappaz
Numerical Analysis for Compressible Viscous Isentropic Stationary Flows

William D. Gropp and David E. Keyes
Domain Decomposition on Parallel Computers

H. Melenk, H. M. Möller, and W. Neun
Symbolic Solution of Large Stationary Chemical Kinetics Problems

Volume 1 (1989), 4 issues — In the U.S.A. and Canada: $80.00; All other countries: $92.00

Volume 2 (1990), 4 issues — In the U.S.A. and Canada: $80.00; All other countries: $92.00
ISSN 0899-8248

Journal of Parallel and Distributed Computing

Kai Hwang
Editor-in-Chief for Special Issues and Invited Papers
University of Southern California, Los Angeles

Howard Jay Siegel
Editor-in-Chief for Submitted Research Papers
Purdue University, West Lafayette, Indiana

This international journal is directed to researchers, engineers, educators, managers, programmers, and users of computers who have particular interests in parallel processing and/or distributed computing. The **Journal of Parallel and Distributed Computing** publishes original research papers and timely review articles on the theory, design, evaluation, and practices of parallel and/or distributed computing systems.

Volumes 8–10 (1990), 12 issues — In the U.S.A. and Canada: $261.00; All other countries: $324.00
ISSN 0743-7315

Sample copies and privileged personal rates are available upon request.

Segmental expression of Hox-2 homoeobox-containing genes in the developing mouse hindbrain

David G. Wilkinson, Sangita Bhatt, Martyn Cook, Edorado Boncinelli* & Robb Krumlauf

Laboratory of Eukaryotic Molecular Genetics, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA, UK
* International Institute of Genetics and Biophysics, Via Guglielmo, Marconi 10, 80125 Naples, Italy

The vertebrate hindbrain develops in a segmental pattern, with distinctive groups of neurons originating from different segments. We report here that members of the Hox-2 cluster of murine homoeobox genes are expressed in segment-specific patterns in the developing hindbrain, with successive genes having boundaries at two-segment intervals. These data indicate that *Hox* genes specify segment phenotype, a role analogous to that of their *Drosophila* homologues.

A WIDESPREAD phenomenon in animal development is the process of segmentation, in which reiterated blocks of tissue generate homologous, yet distinct structures along the body axis. In higher vertebrates, it seems that in the trunk the mesodermal somites are the dominant segmental structures, whereas the central nervous system (spinal cord) is not intrinsically segmented[1]. But the existence of repeated bulges (rhombomeres) during early stages of hindbrain development in vertebrates indicates that the hindbrain might be segmented[2-8], and recent evidence has substantiated this view. Studies of the chick embryo have shown that rhombomeres(r) 2-6 are bounded by sulci that restrict specific populations of developing motoneurons[9]. Neurogenesis is initiated in alternating rhombomeres (r2, r4 and r6), and the Vth, VIIth and IXth cranial nerves arise from successive pairs of rhombomeres (r2 and 3, r4 and 5, and r6 and 7, respectively), indicating the existence of mechanisms operating at two-segment intervals[9]. Further evidence for segmentation of the hindbrain was found by analysis of the expression of the zinc-finger-encoding gene *Krox-20* in the mouse embryo[10]. The expression of *Krox-20* was found to be restricted to two alternate rhombomeres (r3 and r5) in the 9.5-day-old embryo, with the boundaries of expression occurring at rhombomeric sulci. Two domains of *Krox-20* expression were also detected in the hindbrain of the 8.5-day-old embryo, before the appearance of rhombomeres, indicating that segments are established at this stage. Although these data reveal the segmental mechanisms that underlie the organization of the hindbrain, the molecular basis of segmentation and of the specification of differences between the structures arising from each segment is not known.

In *Drosophila*, a diverse group of genes are involved in subdividing the embryo into segments, and the class of *Antennapedia*-like homoeobox genes (the HOM-C genes[11]) specify segment phenotype according to position along the antero-posterior axis[12-15]. An important feature of this process is that these homoeobox genes are expressed in segment-restricted patterns. Murine homologues of the *Antennapedia*-class of homoeobox genes, termed the *Hox* genes, have been isolated[16-28] and shown to be organized in at least four clusters with homology to the *Drosophila* Bithorax (BX-C)[29] and Antennapedia (ANT-C)[30] complexes. Related genes in the murine and *Drosophila* clusters have extended sequence identity and are organized in the same order along the chromosome, indicating that they are derived from a common ancestor[11,20,21]. Moreover, there is a similar correlation between the position of a gene in the *Drosophila* and mouse complexes and its pattern of expression along the antero-posterior axis of the embryo. Members at the 5′ end of each cluster are expressed in posterior regions, and successively more 3′ genes exhibit progressively more anterior domains of expression[20,21,31] In the mouse central nervous system (CNS), each of the *Hox* genes is expressed in a domain which extends from the caudal end of the neural tube to an anterior limit in the spinal cord or hindbrain[31-41]. In the absence of direct evidence for segmentation of the CNS, it has been suggested that these patterns indicate roles for *Hox* genes in positional specification independent of segmental processes. In light of the recent evidence for segmentation of the hindbrain, it seems that *Hox* genes could be involved in specifying segment phenotype in the neural tube. Previous studies have largely focused on stages subsequent to the disappearance of rhombomeres, so we examined the expression of Hox-2-cluster genes during the formation of hindbrain segments. We found that the boundaries of expression of the *Hox-2.6*, *-2.7* and *-2.8* genes are at the anterior sulci of r7, r5, and r3 in the 9.5-day-old embryo, and thus occur at two-segment intervals. By contrast, *Hox-2.9* expression is restricted to a single rhombomere, r4. Analysis of 8 to 8.5-day-old embryos showed that *Hox*-gene expression is initiated at the posterior end of the neural tube, and then extends to the appropriate anterior limit after the establishment of *Krox-20* expression, yet before the formation of overt rhombomeres. Segment-restricted *Hox* gene expression seems to occur therefore, after the formation of segments, consistent with *Hox* genes having a role in specifying segment phenotype rather than in the process of segmentation.

Rhombomeric expression of Hox-2-cluster genes

Earlier studies showed that the *Hox-2.1*, *-2.6* and *-2.7* genes are arranged in a 5′-3′ order in the Hox-2 cluster and have progressively more anterior limits of expression in the hindbrain of the 12.5-day-old embryo[19,20]. Two further genes, *Hox-2.8* and *-2.9*, have now been cloned and linked further downstream of the *Hox-2.7* gene in mice (M. Rubock, H. Lehrach, M.C. and R.K., unpublished results; M.C., R.K. and E.B., unpublished results) and humans[42,52]. We analysed the expression of these genes in coronal sections of 9.5-day-old embryos, in which the presence of the otocyst adjacent to r5 and r6 (ref. 7) allows the identity of rhombomeres to be unambiguously assigned.

The boundary of *Hox-2.1* expression was located at approximately the hindbrain-spinal cord boundary (at the level of the 4th somite), and thus lies caudal to the most posterior hindbrain segment (Fig. 1*a*, *b*). The expression of *Hox-2.6* (Fig. 1*c*, *d*), *-2.7* (Fig. 1*e-h*) and *-2.8* (Fig. 1*i-l*), however, had anterior limits at the anterior sulci of r7 (the posterior sulcus of r6), r5 and r3, respectively. The boundaries of expression of these successive

Hox genes occur, therefore, at two-segment intervals, with the limit of *Hox-2.6* expression at the most posterior segment boundary. The expression of *Hox-2.7* and *-2.8* exhibited quantitative differences along the neural tube. Higher levels of *Hox-2.7* expression were detected in r5 than in more posterior segments (Fig. 1*e, f*), and *Hox-2.8* transcripts were more abundant in r3–r5 than in more caudal regions (Fig. 1*i, j*). In contrast to the other Hox-2 genes, *Hox-2.9* expression was confined to a single rhombomere, r4, in the hindbrain (Fig. 1*m–p*), and is thus flnaked by domains of *Krox-20* expression (Fig. 1*s, t*). In addition, *Hox-2.9* transcripts were detected more caudally in the spinal cord (data not shown). Expression of *Hox-2.8* (Fig. 1*k, l*) and *-2.9* (Fig. 1*q, r*) occurred in the VIIth/VIIIth ganglia (located adjacent to r4), whereas expression of *Hox-2.1, -2.6* or *-2.7* was not detected in these ganglia.

Establishment of segmental patterns

We have previously shown that *Krox-20* expression occurs in two domains in the hindbrain of the 8.5-day-old embryo, and is later found restricted to r3 and r5 (ref. 10) These data indicate that segmentation of the hindbrain occurs before the appearance of rhombomeres, and that *Krox-20* expression can be used to mark the locations of prospective rhombomeric sulci. We analysed the onset of *Krox-20* expression in more detail, and found that initially one stripe of expression appears at 8 days of development (Fig. 2*a–d*), and that two domains of expression have formed at 8.5 days (Fig. 2*e, f*). The initial site of *Krox-20* expression is immediately adjacent to the preotic sulcus[8] (pro-rhombomere A), which flanks the anterior stripe of *Krox-20* expression in the 8.5-day-old embryo, so we inferred that *Krox-20* expression occurs in the prospective r3 before it does in r5. At later stages the down regulation of expression also occurs in r3 before it does in r5 (Fig. 2*g, h*, and ref. 10). These findings may reflect the general antero-posterior direction of CNS maturation.

Expression of *Hox-2.6* (Fig. 3*a, b*), *Hox-2.7* (Fig. 3*d, e*), and

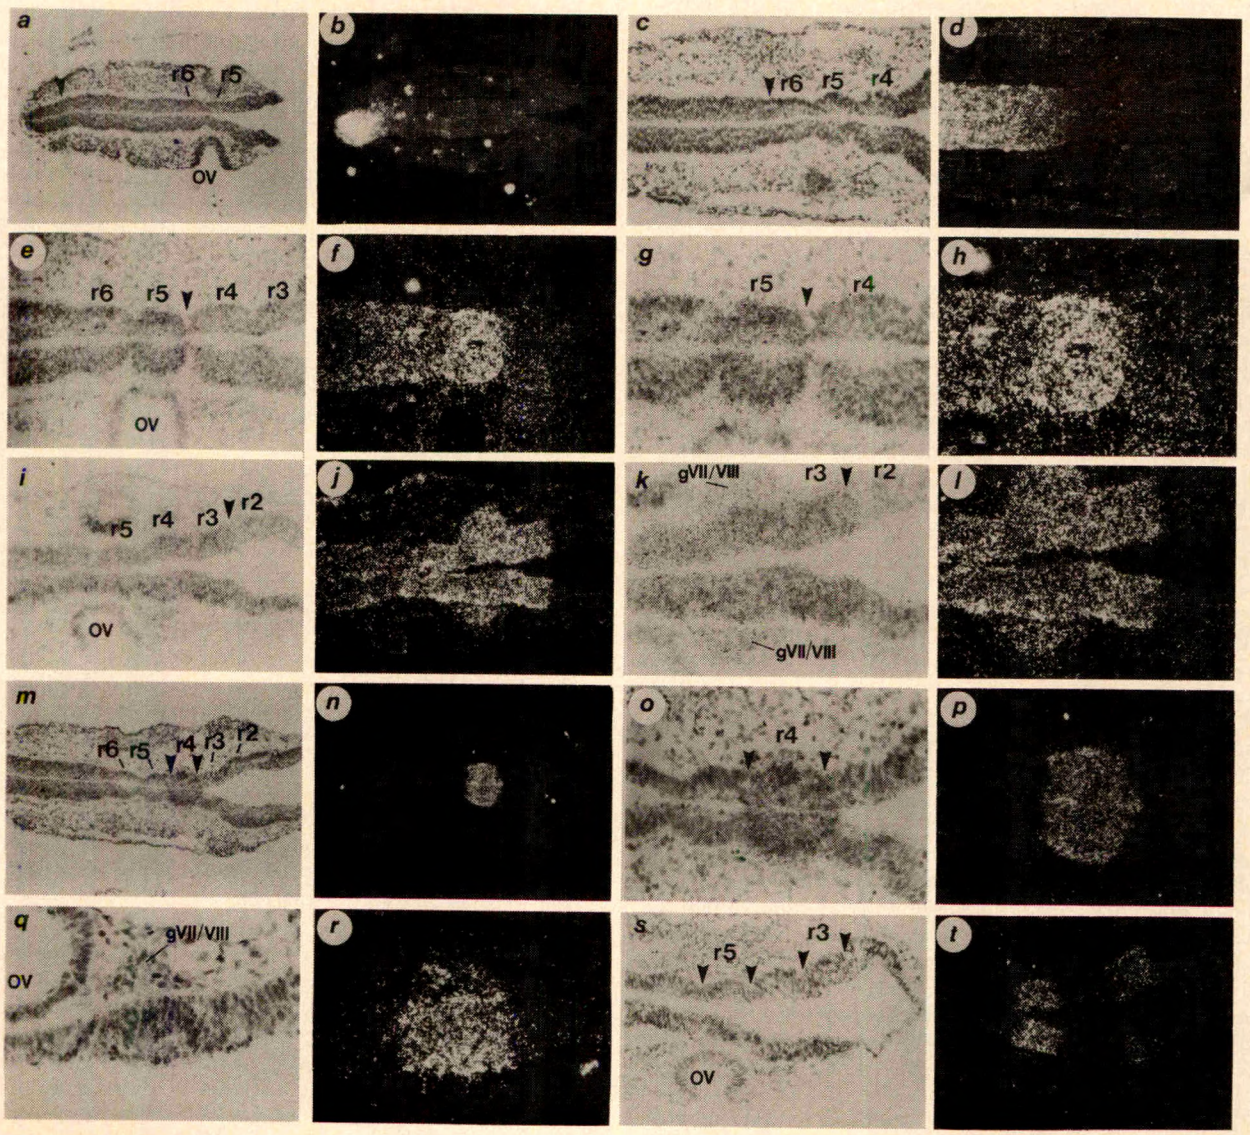

FIG. 1 Expression of Hox-2-cluster genes in the 9.5-day-old mouse-embryo hindbrain. The relationship between Hox-2-gene expression and rhombomeres was determined by *in situ* hybridization of coronal sections of embryos with probes from the following genes: *a, b, Hox-1.1*; *c, d, Hox-2.6*; *e–h, Hox-2.7*; *i–l, Hox-2.8*; *m–r, Hox-2.9*; *s, t, Krox-20*. For each pair, the left micrograph is a brightfield photograph, and the right micrograph is the correspondlng darkfield photograph. Rhombomeres are numbered and the boundaries of *Hox*-gene expression are indicated with arrows. OV, otic vesicle; gVII/VIII, VIIth/VIIIth ganglia. At this stage, rhombomeres are approx. 70 μM in length. The micrographs were taken at the following magnifications; ×25 (*a, b*); ×33 (*c, d, s, t*); ×40 (*i, j*); ×50 (*e, f, m, n*); ×66 (*k, l, o, p*); ×80 (*g, h*); ×100 (*q, r*).

METHODS. *In situ* hybridization of sections with ^{35}S-labelled RNA probes and washing at high stringency was performed as previously described[50]. The probes corresponded to the following fragments: *Hox-2.1* and *-2.6* (ref. 20); *Hox-2.7*, 700 base pairs (bp) *Bam*HI–*Hin*dIII; *Hox-2.8*, 300-bp *Taq*I; *Hox-2.9*, 800-bp *Eco*RI; *Krox-20* (ref. 10).

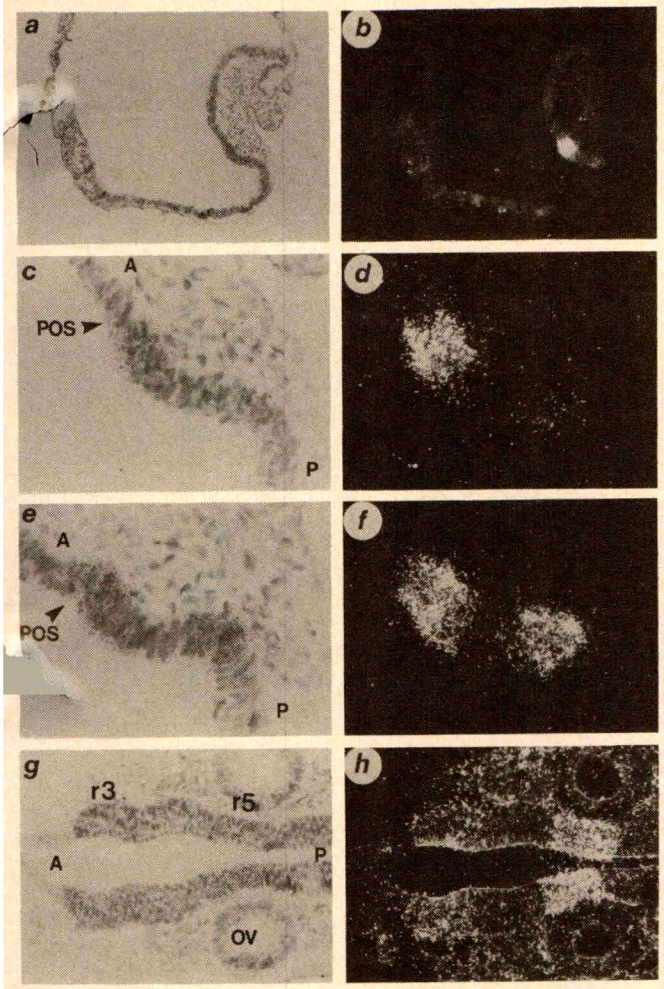

FIG. 2 Expression of *Krox-20* in 8 to 8.5-day-old mouse embryos. *In situ* hybridization of *Krox-20* was carried out against longitudinal (*a–f*) or coronal (*g, h*) sections of mouse embryos. *a–d*, 8.0-day-old embryo. *e, f*, 8.5-day-old embryo. *g, h*, 10-day-old embryo. Left column, brightfield photographs; each correspond to its adjacent darkfield photograph. Rhombomeres are numbered. A, anterior; P, posterior; POS, preotic sulcus; OV, otic vesicle. Only low levels of *Krox-20* transcripts are detected in r3 in the 10-day-old embryo. Embryos were staged according to somite number as described by Theiler[51]. The micrographs were taken at the following magnifications: ×33 (*a, b*); ×50 (*g, h*); ×100 (*c–f*). Experimental methods as described in the legend to Fig. 1.

Hox-2.9 (Fig. 3*g, h*) was detected only at the posterior end of the neural plate in 8-day-old embryos, which show only a single stripe of *Krox-20* expression. These domains of *Hox* expression are substantially caudal to the site of *Krox-20* expression (Fig. 3*c, f, i*) and to the anterior segmental limit of expression of these *Hox* genes found at 9.5-days of development (Fig. 1). But by 8.5 days *Hox-2.9* expression was detected in the hindbrain in a domain that is flanked by two stripes of *Krox-20* expression (Fig. 4*a–f*), and *Hox-2.8* expression extended to a boundary at the anterior-most limit of *Krox-20* expression (Fig. 4*g–l*). These positions of the *Hox-2.8* and *-2.9* expression domains relative to the *Krox-20* expression domain are the same as those in the 9.5-day-old embryo. Thus, it seems that the expression of *Hox* genes becomes established in a posterior–anterior manner, and that their segment-restricted domains of expression arise before the formation of definitive rhombomeres.

Segmental expression of *Hox* genes

Although the expression of different *Hox* genes in distinct overlapping domains is consistent with their having a role in specifying region-specific pattern, the biological significance of the anterior boundaries of expression was not apparent from previous studies. Based on studies of *Hox-1.5*-gene expression it has been suggested that the boundaries of *Hox*-gene expression might have a possible relationship with rhombomeres[41]. Here we have shown that the four 3′-most members of the Hox-2 cluster are expressed in segment-restricted patterns, indicating that they play a part in specifying segment phenotype.

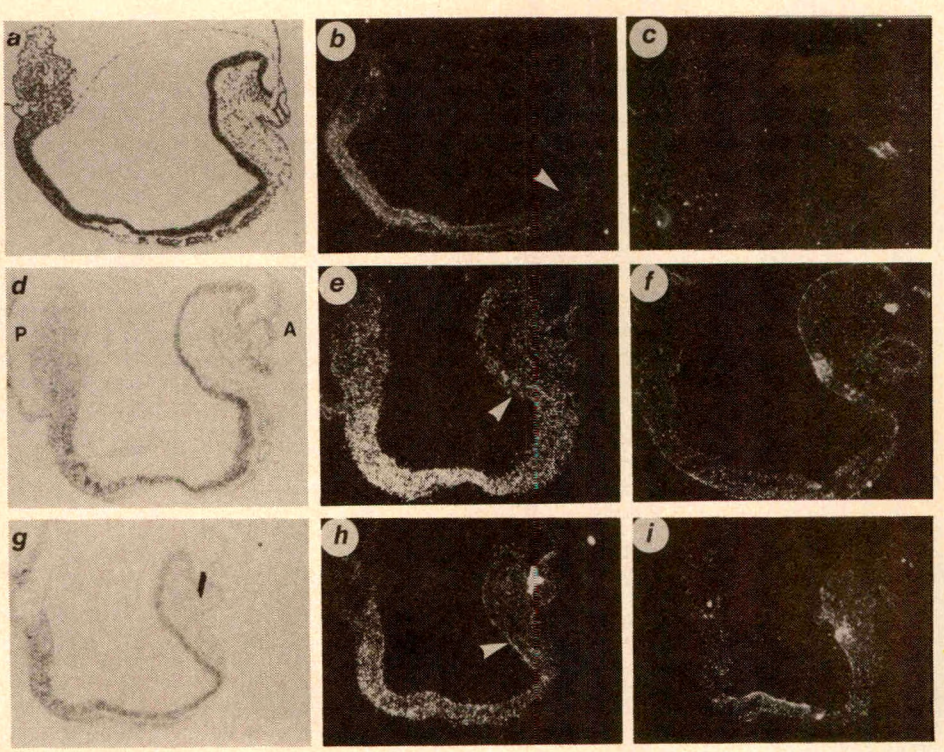

FIG. 3 Expression of Hox-2-cluster genes in 8-day-old mouse embryos. Longitudinal sections of embryos were hybridized with probes from the following genes: *a, b, Hox-2.6*; *d, e, Hox-2.7*; *g, h, Hox-2.9*; *c, f, i, Krox-20*. Left column, brightfield photographs; each corresponds to its adjacent darkfield photograph (centre columns). Centre and right columns, darkfield photographs of adjacent sections hybridized with Hox-2-gene and *Krox-20* probes, respectively. The location of the prospective boundaries of Hox-2-gene expression at 9.5-days (relative to *Krox-20* expression; see Fig. 1) are indicated with arrows. The prospective boundary of *Hox-2.6* indicated is immediately anterior to the first somite, as at 9.5 days of development. A, anterior; P, posterior. All micrographs were taken at ×33 magnification. Experiments performed as described in the legend to Fig. 1.

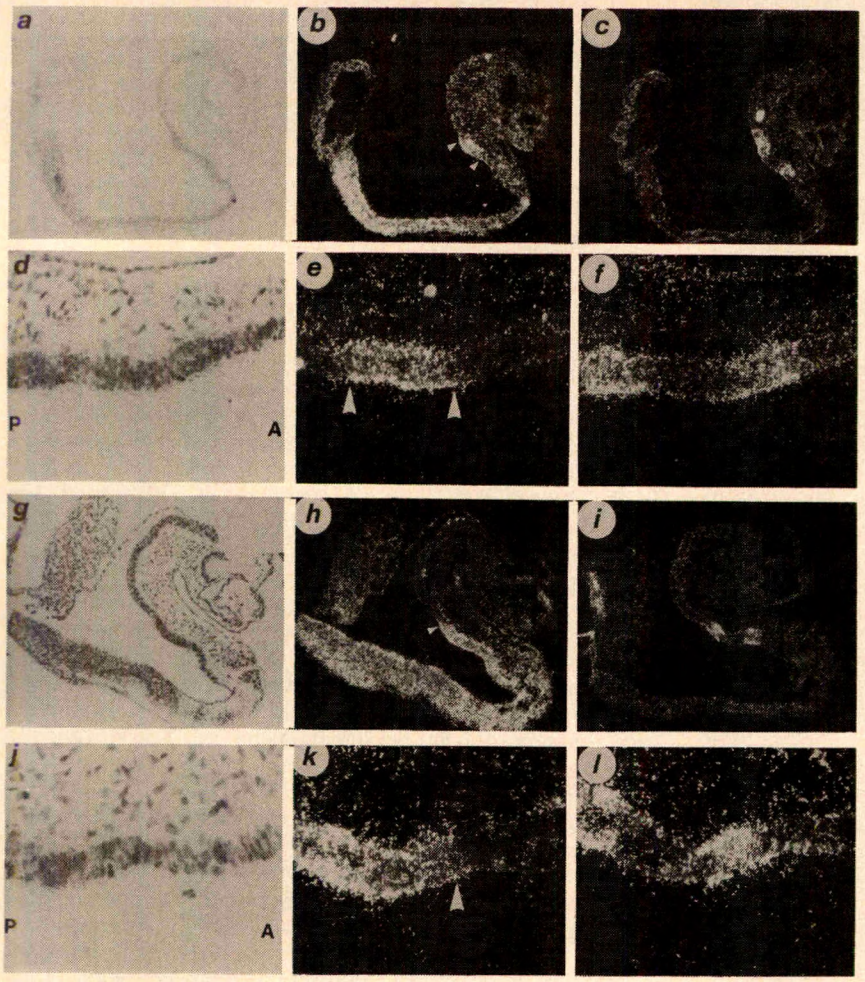

FIG. 4 Expression of Hox-2-cluster genes in 8.5-day-old embryos. Longitudinal sections of embryos were hybridized with the probes from the following genes: *a, b, d, e, Hox-2.9*; *g, h, j, k, Hox-2.8*; *c, f, i, l, Krox-20*. Left column, brightfield photographs; each corresponds to its adjacent darkfield photograph of the centre column. Centre and right columns, darkfield photographs of adjacent sections hybridized with Hox-2-gene and *Krox-20* probes, respectively. The higher-magnification photographs shown in *d–f*, and *j–l* are in the inverse orientation relative to those in *a–c*, and *j–l*. The locations of the limits of *Hox*-gene expression are at the same positions relative to the domains of *Krox-20* expression as they are 9.5 days. A, anterior; P, posterior. The micrographs were taken at the following magnifications: ×25 (*a–c*); ×33 (*g–i*); ×100 (*d–f, j–l*). Experimental methods as described in the legend to Fig. 1.

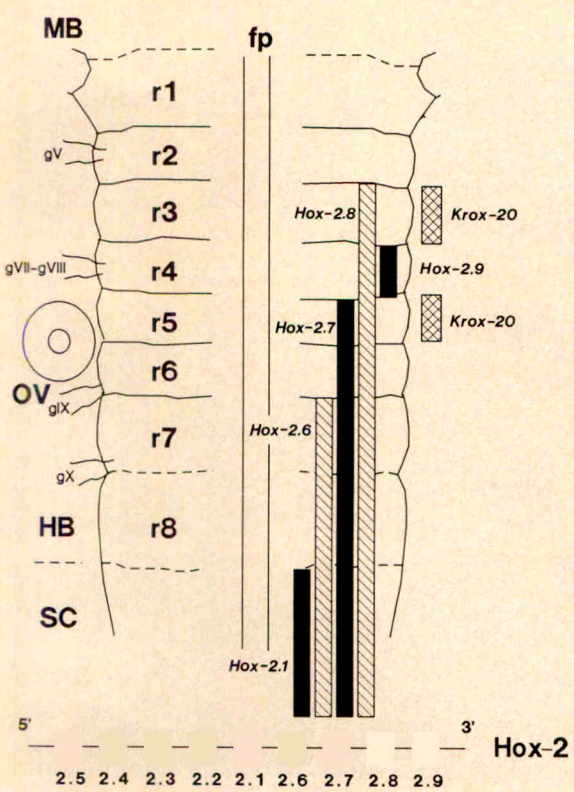

FIG. 5 Summary of Hox-2-cluster gene expression in the 9.5-day-old mouse hindbrain. The lower part illustrates the physical order of the Hox-2-cluster genes on chromosome 11. In the upper part, rhombomeres (r1–r8), the otic vesicle (OV) and the cranial ganglia (gV, gVII/VIII, glX and gX) are represented on the left and the domains of Hox-2-gene and *Krox-20* expression are shown on the right. The anterior limits of r1 and r8 are indicated with dashed lines as they have not been shown to represent segment boundaries. MB, midbrain; HB, hindbrain; SC, spinal cord; fp, floor plate. For simplicity, the relationship between branchiomotor nerves and rhombomeres is not indicated; see Fig. 4 of Lumsden and Keynes (ref. 9) for details.

Our data argue against a function for these genes in the process of segmentation, because the anterior boundaries of *Hox*-gene expression are established after localized *Krox-20* expression. It seems that *Hox*-gene expression is established in a posterior–anterior direction along the neural tube until it reaches the appropriate previously-formed segment boundary. It seems, therefore, that the mechanisms that underlie the establishment of the domains of *Hox*-gene expression do not correlate with CNS maturation, which occurs in an anterior–posterior direction.

It is intriguing that the limits of *Hox-2.6*, *-2.7* and *-2.8* expression occur at two-segment intervals (Fig. 5), because the same periodicity has been shown by studies of the patterns of neuronal development[9] and by the expression of *Krox-20*[10]. Pairs of rhombomeres express different combinations of these genes, although these are offset by one segment from the pairs of rhombomeres (r2 and 3, r4 and 5, r6 and 7) that contribute to individual branchial motor nerves (compare Fig. 5 with Fig. 4 of Lumsden and Keynes[9]). However, the VIth nerve, a somatic motor nerve, arises from r5 and 6, and this pair of rhombomeres lies in phase with the pattern of Hox-2-gene expression. It will be interesting to ascertain whether other hindbrain nuclei arise from pairs of rhombomeres offset from the branchiomotor system. The expression of *Hox-2.9* is restricted to r4 in the hindbrain and thus could be involved in specifying the phenotype of this particular segment. It is puzzling that expression of this gene does not continue the trend of increasingly anterior expression of successive Hox-2 genes[20]. We note, however, that continuation of the two-segment intervals between the boundaries of Hox-2-gene expression would predict a limit of *Hox-2.9* expression at the anterior end of r1, and that evidence that this rhombomere is a true segment is lacking. The patterns of expression that we have described are not sufficient to specify all the features of the hindbrain, in particular the pairs of rhombomeres that generate the branchiomotor system. Thus, it is pertinent to examine whether members of Hox clusters on other chromosomes exhibit segmental patterns of expression identical to, or offset from those of the Hox-2 cluster[53].

Hox-2-cluster gene expression in the neural crest

Hindbrain segments have a number of functional interconnections with neural crest derivatives; for example, cranial ganglia are associated with specific rhombomeres[7], and the segmentally-arranged branchiomotor nerves innnervate specific branchial arches[9]. A possible mechanism that might underlie these spatial relationships is that neural crest is patterned according to its rhombomeric orgin[9,43–45]. Therefore, it may be significant that only *Hox-2.8* and *-2.9* are expressed in the VIIth/VIIIth ganglia, located adjacent to r4, as it is only these Hox-2 genes that are expressed in r4 (Fig. 5). Other Hox-2 genes also exhibit restricted expression in the cranial ganglia, because *Hox-2.7* expression occurs in the IXth and Xth ganglia (A. Graham and R.K., unpublished results), and *Hox-2.1* expression occurs only in the Xth ganglion[33].

Evolution of segmental homoeobox gene expression

In this study we have focused on the Hox-2-cluster genes expressed in the segmented hindbrain. The significance of the boundaries of the other Hox-2 genes (*Hox-2.5*, *-2.4*, *-2.3*, *-2.2* and *-2.1*) which lie in the spinal cord is not clear, however. For *Hox-2.1*, the limit of expression occurs in the vicinity of the hindbrain/spinal cord border, and thus may correlate with a transition in CNS organization. Although current evidence argues against the existence of segment boundaries in the caudal hindbrain and spinal cord of higher vertebrates, lower vertebrates do have segmentally arranged neurons in these regions[46,47]. Segmentation seems, therefore, to have been retained in the upper hindbrain of higher vertebrates, but lost from more caudal parts of the neural tube[9]. It is possible that *Hox*-gene expression does respect spinal cord segments in lower vertebrates, and the location of these boundaries have been retained in higher vertebrates despite the loss of intrinsic segmentation.

The similarities in the structure and expression of *Antennapedia*-like homoeobox genes in *Drosophila* and mice indicate that they have an ancient conserved role in specifying regional variations in pattern along the body axis[11,20,21]. Although such a function need not be coupled to segmentation, the finding that the expression of the *Hox* and HOM-C genes is segment-restricted in these diverse organisms is evidence for their having a conserved role in specifying segment phenotype. But because segmentation seems to have arisen separately in the lineages that lead to arthropods and vertebrates[48,49], the coupling of homoeobox-gene expression to segments may have evolved independently in mice and *Drosophila*. □

ACKNOWLEDGEMENTS. We thank Dario Acampora, Anthony Graham and Andrew Lumsden for suggestions and discussions. We also thank Melissa Rubock and Hans Lehrach for allowing us to refer to the cloning and characterization of the mouse *Hox-2.8* gene prior to publication. Part of the work was supported by CNR Project on Biotechnology and by AIRC.

Structure and associated DNA-helicase activity of a general transcription initiation factor that binds to RNA polymerase II

Mary Sopta, Zachary F. Burton* & Jack Greenblatt

RAP30/74 is a heteromeric general transcription initiation factor which binds to RNA polymerase II. Here we report that preparations of RAP30/74 contain an ATP-dependent DNA helicase whose probable function is to melt the DNA at transcriptional start sites. The sequence of the RAP30 subunit of RAP30/74 indicates that RAP30 may be distantly related to bacterial sigma factors.

ACCURATE initiation of transcription by RNA polymerase II requires several auxiliary protein factors and ATP[1]. The best characterized transcription factors are the sequence-specific DNA-binding proteins, including promoter-binding proteins such as TFIID (the TATA-binding factor)[2-6] and Sp1 (ref. 7), as well as proteins that bind to enhancers and activate transcription in response to particular stimuli. Initiation by RNA polymerase II also requires several less well characterized general initiation factors, sometimes referred to as TFIIB, TFIIE and TFIIF[8-10], which apparently do not recognize DNA in a sequence-specific manner. The general initiation factors are known to interact with RNA polymerase II[11-13], or with each other[12], and enter the initiation complex late in the initiation pathway[12-15]. Their roles in transcription have remained obscure.

We previously identified and purified one of the general initiation factors by affinity chromatography on a column containing immobilized RNA polymerase II[11,15]. This factor, which we call RAP30/74, has two subunits[11,16] with apparent relative molecular masses of 30,000 and 74,000 (RAP30 and RAP74 subunits, respectively). RAP30/74 is required for formation of the first phosphodiester bond at a promoter[15,16]. It is needed for initiation, regardless of whether or not the promoter has a TATA box[16]. RAP30/74 is similar or identical to TFIIF[10], which contains at least the RAP30 subunit of RAP30/74 (ref. 10). TFIIF is one of the components of a less purified fraction, called TFIIE, which has been widely used in many studies of initiation by RNA polymerase II[17,18]. General initiation factors that may be equivalent to RAP30/74 or to its RAP30 subunit have also been described[13,19].

The ability to purify RAP30/74 by affinity chromatography[11] has now enabled us to clone human complementary DNAs that encode RAP30 and to begin the biochemical characterization of RAP30/74. Here we report that RAP30/74 has an associated DNA-helicase activity whose requirement for ATP may partly explain the energy requirement for transcription initiation by RNA polymerase II[1].

Associated DNA-helicase activity

We considered the possibility that RAP30/74 might be required for initiation by RNA polymerase II because it is required to melt the DNA template at the start site of transcription. Accordingly, we tested whether our preparations of RAP30/74 had DNA-melting (that is, helicase) activity.

We purified RAP30/74 from a HeLa-cell nuclear extract by affinity chromatography on a column containing immobilized RNA polymerase II[11,15,16]. To be certain that any activity eluting from the column was associated with RAP30/74, we performed the purification in duplicate (Fig. 1*a*). We pre-treated the HeLa-cell nuclear extract either with antibodies directed against a TrpE-RAP30 fusion protein to deplete the extract of RAP30/74 (Fig. 1*b*, lane 2), or with antibody directed against TrpE (Fig. 1*b*, lane 3) before we loaded it onto either an RNA polymerase II column or a control column. We eluted these columns (Fig. 1*a*) with salt, so that RAP30/74 dissociated from RNA polymerase II[11]. These high-salt eluates were then tested for DNA-helicase activity in a standard assay[20,21] requiring the displacement of a small radiolabelled complementary oligonucleotide which had been annealed to single-stranded M13 DNA (Fig. 1*c*).

The high-salt eluate of the RNA polymerase II column that had been loaded with nuclear extract treated with anti-TrpE antibody had DNA-helicase activity (Fig. 1*c*, lane 6). We confirmed that this was the only eluate that contained RAP30 by western blotting with anti-RAP30 antibody (Fig. 1*b*, lane 6). The dose-response curve for the DNA-helicase activity was roughly linear (Fig. 1*d*) and no unwinding was observed after about 5 minutes (data not shown). The DNA-helicase activity of RAP30/74 was not affected by NaCl concentrations as high as 200 mM (data not shown), even though some DNA helicases are inactive or strongly inhibited under these conditions[22].

The DNA-helicase activity was able to bind to an RNA polymerase II column and not to a control column (see lanes 6 and 7 in Fig. 1*c*, and also Fig. 1*d*); it was specifically removed from a nuclear extract by affinity-purified antibody directed against RAP30 (compare lanes 4 and 6 in Fig. 1*c*). The two subunits of RAP30/74 are the only general initiation factors that bind efficiently to RNA polymerase II[11,15]. Because they are the only proteins in a HeLa-cell nuclear extract that are bound efficiently by both anti-RAP30 antibody and RNA polymerase II[11,15,16], either RAP30/74 is a DNA helicase or the DNA helicase is a different protein that binds to a complex containing both RAP30/74 and RNA polymerase II.

Because the DNA-helicase activity associated with RAP30/74 was not directly inhibited by affinity-purified polyclonal antibody directed against RAP30 (data not shown), it is unlikely that the RAP30 subunit of RAP30/74 is necessary for DNA helicase activity. We tested whether RAP30 or RAP74 could bind to ATP, because DNA helicases must bind DNA and generally require ATP for their activity[23]. We found that RAP74 can form a covalent complex containing the alpha-phosphate from ATP, and that the formation of this complex is stimulated by DNA (Fig. 2). These observations are consistent with the idea that the RAP74 subunit of RAP30/74 is the DNA helicase.

Nucleotide hydrolysis requirements

RNA polymerase II can accurately initiate transcription only if hydrolysable ATP or dATP is present in the reaction[1,24]. We therefore investigated whether the requirement for ATP in the initiation of transcription reflects a requirement of RAP30/74 for energy in melting a DNA duplex. The DNA-helicase activity

of our RAP30/74 preparation required ATP and could use dATP (lanes 3 and 5, Fig. 3*a*), but could not use GTP, CTP, UTP, dGTP, dCTP or TTP (lanes 6–11). Half-maximal activity was achieved at an ATP concentration of 150 μM (Fig. 3*b*). ATP hydrolysis was necessary because the ATP analogue, AMP-PNP (β-γ-Imidoadenosine-5′-triphosphate), could not substitute for ATP (Fig. 3*a*, lane 4). These features of the DNA-helicase activity associated with RAP30/74 are exactly the same as those that are characteristic of the energy requirement for initiation by RNA polymerase II[1,24].

Sarkosyl sensitivity

Initiation of transcription by a complete rapid-start initiation complex at the adenovirus major late promoter is inhibited by Sarkosyl detergent[25]. The DNA-helicase activity associated with RAP30/74 was inhibited by the same concentrations of Sarkosyl that inhibit initiation by a rapid-start complex[25] (Fig. 3*c*). This indicates that the Sarkosyl sensitivity of a transcriptional initiation complex reflects the Sarkosyl sensitivity of a DNA helicase required to melt the DNA duplex at the promoter.

Sequence of RAP30 subunit of RAP30/74

To analyse the structure and function of RAP30/74, we cloned and sequenced cDNAs encoding the RAP30 subunit. We purified human RAP30 from HeLa cells by RNA polymerase II-affinity chromatography and SDS-polyacrylamide gel electrophoresis, and used it to immunize a rabbit. With the resulting antiserum we screened an expression library in λgt11 (ref. 26) made with cDNAs derived from the human promyelocytic-leukaemia cell line, HL60. A partial RAP30 cDNA obtained in this way was then used as a hybridization probe to isolate cDNAs containing the entire RAP30 coding sequence from a human kidney cDNA library. The 1,426-base pair (bp) DNA sequence up to the first polyadenylation site is shown in Fig. 4. The open reading frame begins with ATG in a context that is typical of mammalian translational start sites[27]. It encodes a protein of 234 amino acids with a predicted relative molecular mass of 26,312.

We confirmed that our cloned cDNAs encoded RAP30. First, affinity-purified antibodies against RAP30-β-galactosidase and TrpE-RAP30 fusion proteins produced in *Escherichia coli*

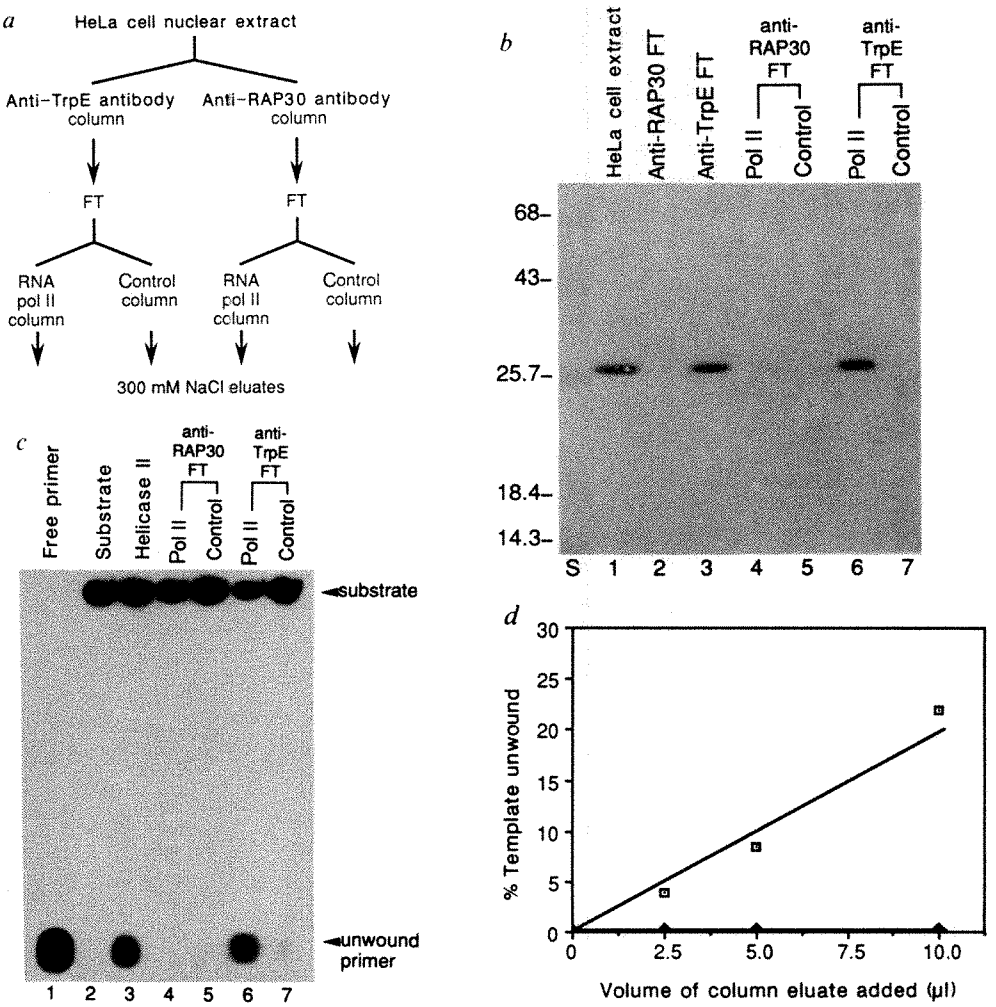

FIG. 1 RAP30 has an associated DNA-helicase activity. *a*, Scheme for the preparation of column fractions. *b*, Western-blot analysis of column fractions using anti-RAP30 antibody. *c* and *d*, DNA helicase activities in RNA polymerase II and control column eluates. Polymerase II denoted by pol II. FT, Flow through.

METHODS. *a*, HeLa-cell nuclear extract (1 ml)[46], containing ~4 ng μl^{-1} of RAP30, was passed through 0.5-ml columns containing immobilized affinity-purified anti-RAP30 antibodies or anti-TrpE antibodies (see below)' at a concentration of 360 μg ml^{-1}. The flow-through from each was then subjected to affinity chromatography on 0.5-ml columns containing immobilized RNA polymerase II (2 mg ml^{-1} protein) and on control columns[11]. The affinity columns were eluted with affinity column buffer[11] containing 0.3 M NaCl. The amounts loaded onto the gel were (μl): HeLa-cell nuclear extract, flow-throughs from anti-RAP30 and anti-TrpE antibody columns, 5; 0.3 M NaCl eluates of RNA polymerase II and control columns, 15. The blot was developed with an alkaline phosphatase-based second antibody reaction (BioRad). Pre-stained molecular weight markers (lane 5) were from Bio-Rad. *c* and *d*, An M13 displacement reaction was used to assay DNA helicase activity[20,21]. The substrate was an end-labelled universal sequencing primer hybridized to M13 single-stranded DNA. DNA helicase assays (20 μl; 20 min at 37 °C) contained 40 mM Tris-HCl, pH 7.9, 4 mM $MgCl_2$, 150 mM NaCl, 1 mM dithiothreitol (DTT), 50 μg ml^{-1} BSA, 2 mM ATP, 0.2 nM DNA substrate, and 10 μl (*c*) or the indicated volumes (*d*) of the column eluates. Reactions were electrophoresed on 15% non-denaturing polyacrylamide gels[47]. The dried gels were exposed to X-ray film Kodak XAR-5. A reaction with 40 ng *E. coli* DNA helicase II (provided by Dr Steve Matson) contained only 75 mM NaCl. The reaction in lane 1 in *c* was incubated for 1 min at 100 °C. The percentage of DNA unwound (*d*) was calculated after subtraction of a background value of 5%. Preparation of anti-RAP30 and anti-TrpE antibodies: The TrpE-RAP30 fusion plasmid pATHR30 was constructed by cloning the RAP30-encoding *Pst*I fragment of p9-2 (see Fig. 3 legend) into the *Pst*I site of pATH10 (ref. 48). The strain JM101 containing either the plasmid pATH10 or pATHR30 was grown as previously described[48] (10 litres of each at 30 °C). TrpE and TrpE-RAP30 were purified from cleared sonicates by precipitation with $(NH_4)_2SO_4$ at 25% saturation. Yields were 75 mg of each at 80–90% purity. Rabbits were immunized[16] with purified TrpE-RAP30. The resulting antisera were affinity-purified on columns containing immobilized TrpE to produce anti-TrpE antibodies (ref. 16). The flow-throughs were purified on columns containing immobilized TrpE-RAP30 to produce anti-RAP30 antibodies (ref. 16).

reacted with human RAP30 in a western blot[16] (Fig. 1*b*). Such antibodies also efficiently and specifically removed RAP30 and RAP74 (by virtue of its tight interaction with RAP30) from a HeLa-cell nuclear extract[16]. Transcriptional activity could only be fully restored to such an extract by the addition of a combination of gel-purified RAP30 and gel-purified RAP74[16]. Second, we determined the N-terminal sequences of three tryptic fragments and one endoproteinase Asp-N fragment of RAP30 that had been purified from HeLa cells by RNA polymerase II-affinity chromatography and gel electrophoresis. These matched perfectly with the amino-acid sequences that were predicted from the RAP30 cDNA sequence (Fig. 4).

An ATP-dependent DNA helicase must bind to DNA and to ATP, and we have shown here that RAP74 has a DNA-regulated ATP-binding site (Fig. 2). We have no evidence that RAP30 can bind to ATP, but there is a Gly-X-X-X-X-Gly-Lys motif at residues 36–42 of RAP30, which is often a part of nucleotide-binding sites[28]. We also examined the predicted amino-acid sequence of RAP30 for canonical 'helix-turn-helix' or 'zinc-finger' DNA-binding motifs[29,30], but there were no obvious candidate sequences in RAP30. RAP30 is very basic (pI = 10.4), with a region of dense positive charge at amino-acid residues 168–182 (Fig. 4). This stretch of amino acids is predicted to form an α-helical structure. The function of this region is unknown, although certain DNA-binding regions[31] are positively charged α-helical structures. Interestingly, the sequence of RAP30 in this region matches 5/5 or 7/11 with half of the proposed DNA-binding region of CREB[32], a DNA-binding protein which mediates responsiveness to peptide hormones that raise intracellular cyclic AMP (Fig. 5*c*). RAP30 has none of the sequence motifs often found in other DNA helicases[33].

RAP30 may belong to the σ-factor family

The predicted amino-acid sequence of RAP30 is not closely related to any other amino-acid sequences in the GENBANK, EMBL and PIR databases. But because RAP30 binds to RNA polymerase II, we compared the sequence of RAP30 directly with those of two bacterial RNA polymerase-binding proteins, NusA and σ^{70}. There was no discernible relationship between RAP30 and the *E. coli* elongation factor NusA (ref. 34), but RAP30 did contain a region of similarity with the *E. coli* initiation factor σ^{70} and its *Bacillus subtilis* equivalent, σ^{43}

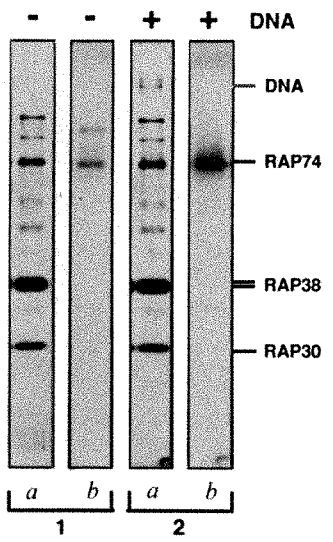

FIG. 2 Covalent labelling of RAP74 with [α-^{32}P] ATP. An RAP fraction radiolabelled with ATP in the presence or absence of DNA was subjected to SDS-PAGE. Lanes 1*a* and 2*a*, silver-stained RAP fractions. Lanes 1*b* and 2*b*, ^{32}P-autoradiography of the same gel lanes. The reaction in lane 2 contained DNA.

METHODS. RAP samples were isolated by affinity chromatography on an RNA polymerase II column and then by ion-exchange chromatography on BioRex 70 (ref. 16). RAP samples were incubated for 1 min on ice in 20 µl buffer containing 12 mM HEPES buffer, pH 7.9, 12% glycerol, 13 mM KCl, 5 mM $MgCl_2$, 0.3 mM DTT, 0.12 mM EDTA, and 0.62 M [α-^{32}P] ATP (811 Ci mmol^{-1}) in the absence or presence of 20 µg ml^{-1} pSmaF DNA digested with *Sma*I (pSmaF is a plasmid containing the adenovirus major late promoter; it is not clear that promoter DNA is required for this labelling reaction). Samples were boiled in buffer containing 1% SDS and 1% 2-mercaptoethanol and electrophoresed. Radiolabelling of RAP74 was stimulated >4-fold by the addition of DNA to the reaction.

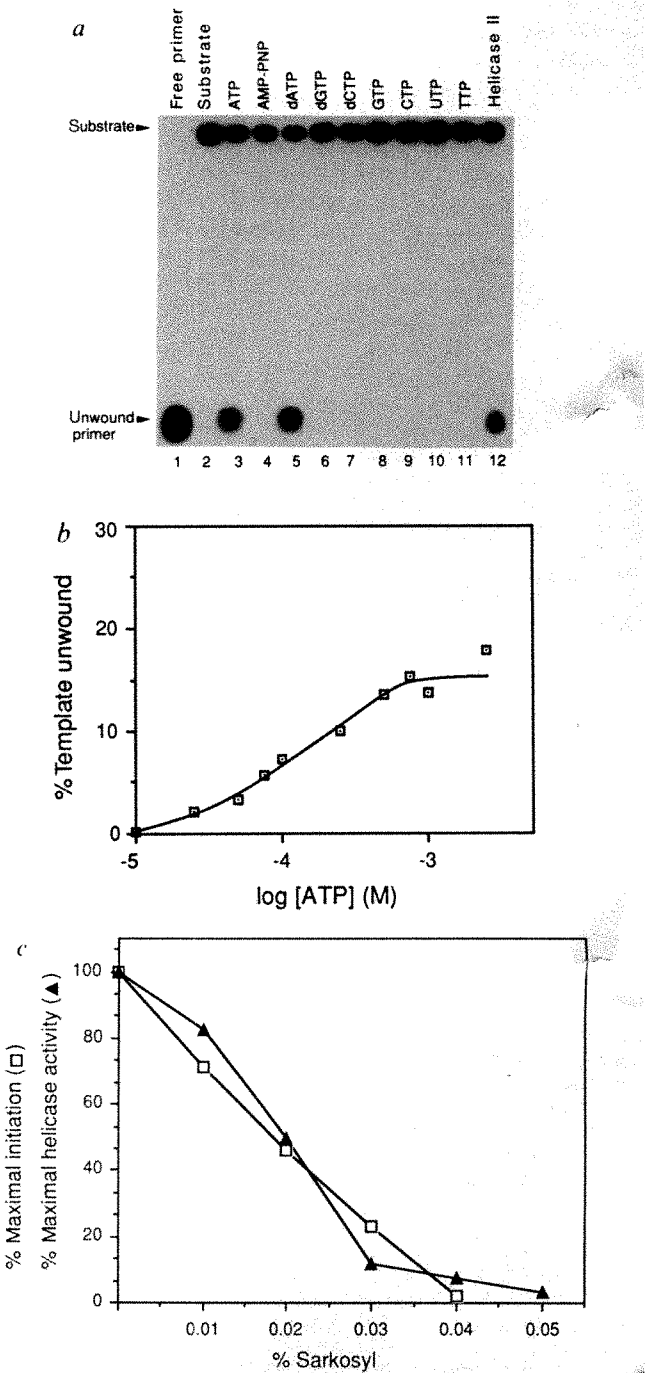

FIG. 3 Nucleotide requirement and Sarkosyl sensitivity of the DNA helicase. Assay conditions were as described in the legend to Fig. 1, except that 2 mM ATP was replaced with the equivalent concentrations of the indicated alternative nucleotides (*a*) or with the indicated concentrations of ATP [ATP] (*b*), and Sarkosyl was included at the indicated concentrations in *c*. The data in *c* on the effect of Sarkosyl on initiation by rapid-start complexes at the adenovirus major late promoter are taken from Hawley and Roeder[25]. All nucleotides were purchased from Boehringer. *E. coli* DNA-helicase II (20 ng) was used as a standard.

(Fig. 5*a*). In particular, the best matches between RAP30 and σ^{70} were in regions 2 and 1*b* of σ^{70}, the only regions that are conserved among all bacterial and bacteriophage sigma factors. These parts of σ^{70} have been postulated to contain the site of the interaction of σ^{70} with the core component of bacterial RNA polymerase[35-37]. Indeed, a tryptic fragment of *E. coli* σ^{70} that retains the ability to bind to the core component of RNA polymerase[38] has end points that are nearly coincident with the boundaries of the proposed homology between σ^{70} and human RAP30 (Fig. 5*a*). An insertion of 245 amino acids in this region is found only in the sequence of *E. coli* σ^{70}. This insertion seems not to have an essential role in the interaction of σ^{70} with RNA polymerase, because it is missing in other σ-factors and because the *rpoD800* deletion in this sequence is not lethal[39].

We used the PIR ALIGN program for statistical analysis of the alignment between RAP30 and σ^{70} in homology region 2. The alignment score was marginally significant[40] and was comparable to, or better than, the alignment scores obtained for comparisons between σ^{70} and bacteriophage σ-factors in this region[36] (Fig. 5*b*), but low relative to those for comparisons among the main σ-factors of *E. coli* and *B. subtilis*. This indicates that, like the bacteriophage σ-factors, RAP30 may be a distantly related member of the σ-factor protein family.

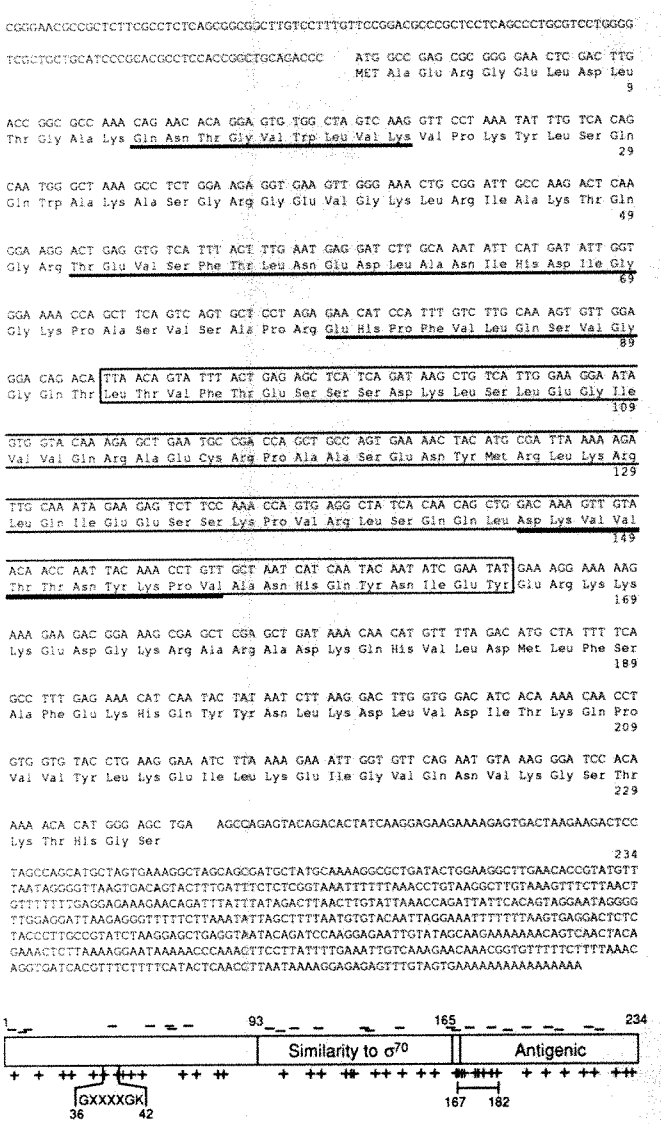
Discussion

We have shown that the RAP30 subunit of the polymerase-binding general initiation factor, RAP30/74, may be distantly related to bacterial σ-factors. Indeed, the best sequence match between human RAP30 and *E. coli* σ^{70} lies in the only part of σ^{70} that is conserved among all σ-factors and is believed to be the RNA polymerase-binding region of σ^{70} (see refs 35 and 36). Bacterial σ-factors recognize promoter sequences and position the core component of RNA polymerase at transcriptional start sites[41]. In eukaryotes, the promoter-recognition function of the σ-factors seems to have become the responsibility of separate DNA-binding proteins such as the TATA-binding factor TFIID[2-6] or Sp1 (ref. 7). By contrast, it seems that the RAP30 subunit of RAP30/74 has assumed the polymerase-binding function of bacterial σ-factors. We have shown previously that RAP30 is bound very stably to rapid-start initiation complexes at the adenovirus major late promoter[10,16], but we do not yet know whether, like σ^{70} (ref. 42), RAP30/74 is released from the transcription complex after the initiation of transcription.

We have also noted a possibly significant resemblance between the highly basic amino acids 164–174 of RAP30 and part of the DNA-binding site of CREB. This implies that RAP30 could be a site-specific DNA-binding protein with limited specificity. Because RAP30 seems not to be the TATA-binding factor[10,15,16], one possibility so far untested is that it could recognize the recently identified initiator element[43] located at some transcriptional initiation sites.

We have also shown that our preparations of RAP30/74 contain a DNA-helicase activity which must be bound, either directly or indirectly, to RAP30. The most obvious candidate for the DNA helicase is RAP74, but we have still not formally excluded the possibility that the DNA helicase is another polypeptide that binds to RAP30. We suggest that at least part of the role of RAP30 is to properly position the DNA helicase in the initiation complex by interacting with RNA polymerase II. The DNA-helicase would then melt the DNA at the correct site and cause isomerization from a closed complex to an open complex by analogy with the situation in bacteria[41].

The distance from a TATA box to a transcriptional start site for mammalian promoters is different from that for promoters



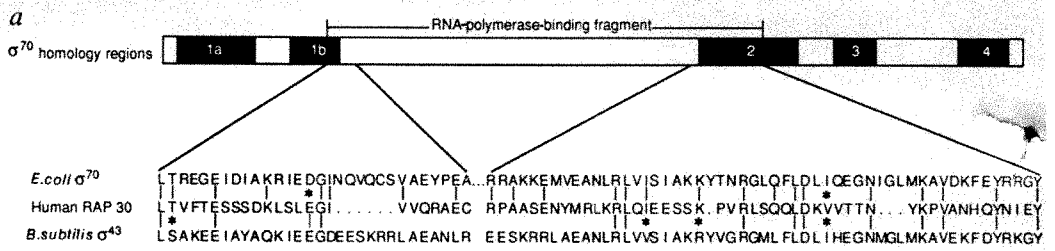


FIG. 4 Sequence of human RAP30 cDNA. The boxed sequence represents the region of RAP30 that matches best with *E. coli* σ^{70} (Fig. 4). The major antigenic epitopes of human RAP30 are found in its 66 C-terminal amino acids (unpublished data). A potential nucleotide binding motif (Gly-X-X-X-X-Gly-Lys)[28] is found at amino-acid residues 36–42. The four amino-acid sequences underlined in bold indicate the N-terminal sequences that were determined for three tryptic fragments and one endoproteinase Asp-N fragment derived from human RAP30. The bar at the bottom shows the positions of various motifs in the RAP30 coding sequence and the distributions of positively and negatively charged amino acids in the protein.

METHODS. Rabbit antiserum raised against human RAP30 that was purified by RNA polymerase II-affinity chromatography and SDS-gel electrophoresis[16] was used to screen a cDNA expression library in λgt11[26] derived from HL60 human promyelocytic leukaemia cell messenger RNA (provided by Dr G. D'Agostaro). Two identical 750-bp clones (30-2A and 30-2B) were identified in a screen of 3×10^6 recombinants and sequenced on both strands using the sequenase system (USB). They encoded the 66 amino acids at the C-terminal end of RAP30, a 3′ untranslated region, and a poly(A) tail. This cDNA (30-2A) was then used to screen by hybridization[47] a human kidney cDNA library constructed in λgt10[26] (provided by Dr Graeme Bell). Three identical clones with 2-kilobase (kb) inserts were isolated (9-1, 3-1, 10-1). Restriction fragments of clone 9-1 were subcloned into pEMBL18 and sequenced on both strands. The cDNA contained a 234-amino-acid open reading frame and a 3′ untranslated region that was identical to the sequence of 30-2A up to the point at which poly(A) was added in 30-2A. The 3′ untranslated region of the 9-1 clone continued beyond this point and did not end in poly(A) tail. The cDNA sequence that is shown has the shorter 160-cell version of the 3′ untranslated region. RAP30 that was purified by affinity chromatography and gel electrophoresis was also digested with sequencing grade trypsin or endoproteinase Asp-N (Boehringer) and the proteolytic fragments were separated by HPLC on a C8 column (RP300, Applied Biosystems). The N-terminal sequences of three tryptic fragments and one endoproteinase Asp-N fragment were determined on an Applied Biosystems Pulse Liquid Protein Sequenator (Michigan State Univ. Macromolecular Structure Facility).

RAP30 (164) EYERKKKEDGK
CREB (299) ECRRKKKEYVK

FIG. 5 Comparisons of RAP30 with σ^{70} and with the DNA-binding site of CREB. *a*, The predicted RAP30 protein sequence was compared directly with the sequence of the major sigma factor in *E. coli*, σ^{70}, using the ALIGN program in BIONET. The shaded parts of the bar represent the various regions of σ^{70} that are conserved among σ-factors[36]. The best match between RAP30 (residues 118–165) and σ^{70} (residues 373–425) (31% identity) involved part of region 2 as indicated, whereas the second-best match (28% identity) involved part of region 1b (residues 94–117 in RAP30, residues 111–139 in σ^{70}). Regions 1*b* and 2 are separated by 245 amino acids in σ^{70}, but are directly adjacent in other bacterial and phage σ-factors. The line represents a tryptic fragment of σ^{70} that retains the ability to interact with the core component of RNA polymerase[38]. *b*, Statistical analysis of the alignment that is shown for region 2 used the modified Dayhoff alignment program (ALIGN) in the Protein Identification Resource (PIR). This alignment was compared with all other possible alignments of RAP30 with 100 random permutations of the σ^{70} sequence in this region. Other bacterial and bacteriophage σ-factors were also compared with σ^{70} in the same region, using the alignments given by Gribskov and Burgess[36]. All scores >3 are significant. The various alignment scores are shown in rank order. Each represents the number of standard deviations by which the given alignment is greater than the average for random alignments. *c*, A possible alignment of amino acids 164–174 RAP30 with amino acids 299–309 in the DNA-binding site of CREB[32].

in the yeast *Saccharomyces cerevisiae*. Because the characteristic mammalian spacing is preserved when the yeast TATA-binding factor replaces TFIID, its mammalian counterpart, in a mammalian transcription system, it has been suggested that a different general factor determines the spacing[5,6]. The spacing may be determined by RAP30/74 if RAP30/74 has a role in positioning RNA polymerase II, or if the precise site at which RNA polymerase II initiates transcription is determined by the precise site at which RAP30/74 melts the DNA template.

Neither initiation by eubacterial RNA polymerase nor initiation by eukaryotic nuclear RNA polymerases I and III is believed to have a requirement for ATP. We consider that the unique energy requirement for accurate initiation by RNA polymerase II[1] is at least partly explained by the ATP requirement of the DNA-helicase activity that is bound to RAP30. The assay we have used in our present studies for DNA-helicase activity is artificial in that the helicase is not positioned at a promoter by a complete initiation complex. The DNA helicase that is associated with RAP30 and initiation by a rapid-start complex containing RNA polymerase II are inhibited by the same concentrations of Sarkosyl, and there is an exact correspondence between the nucleotides that can be used by the DNA helicase and those that can be used for accurate initiation by RNA polymerase II[1,24]. This indicates that we have identified a DNA helicase required for accurate initiation of transcription at promoters by human RNA polymerase II.

The transition from a closed initiation complex to an open complex is a target for regulation in bacteria. In particular, the λ phage cI repressor activates transcription at the Prm promoter in this way[44], and so does the phosphorylated enhancer-binding protein NR_I of *E. coli* when it activates the *glnAp2* promoter[45]. Eukaryotic transcriptional activators may, in some cases, similarly regulate the RAP30-associated DNA helicase. The availability of a cloned human RAP30 cDNA and of a simple enzymatic assay for the activity of a DNA helicase associated with RAP30 should facilitate the further analyses of protein–protein interactions and mechanistic steps involved in the initiation and regulation of transcription.

ACKNOWLEDGEMENTS. We thank C. J. Ingles, R. Dunn, D. Fitzpatrick, L. Allison, M. Moyle and V. Watt for advice on cloning and sequencing; S. Kelly, J. Leykam and M. Corlew for help with protein sequencing; S. Matson for advice on DNA helicase assays, and C. J. Ingles, J. Segall, S. McCracken and M. Killeen for materials and for critically reading the manuscript.

Novel putative receptor tyrosine kinase encoded by the melanoma-inducing *Tu* locus in *Xiphophorus*

Genzentrum, Max-Planck-Institut für Biochemie, Am Klopferspitz 18a, D-8033 Martinsried, FRG

Malignant melanoma in *Xiphophorus* fish hybrids is caused by the activity of a dominant oncogene *Tu*. By combining genetic and molecular approaches, we have isolated the melanoma oncogene. We show that its level of expression correlates with the degree of malignancy of the tumour. The corresponding proto-oncogene is developmentally regulated. The *Tu* gene codes for a novel receptor tyrosine kinase which is closely related to the receptor for epidermal growth factor.

TUMORIGENESIS is generally considered to be controlled by oncogenes, which specify many of the malignant features of tumour cells. Oncogenes arise mainly by activation of their normal cellular counterparts, proto-oncogenes, which themselves seem to have essential roles in normal cellular physiology and are often involved in the regulation of normal cell proliferation and differentiation. By contrast, there are other genes, which are believed to be critically involved in the negative control of cell growth[1], that must be mutated at both alleles for the neoplastic phenotype of the cell to develop[2,3]. These observations have led to the distinction between recessive oncogenes (otherwise known as tumour suppressors or anti-oncogenes) and dominant oncogenes. Although the structure and molecular function of many oncogenes are well established, the evidence that their activation is indeed the primary cause and not a consequence of tumorigenesis in the intact organism is generally circumstantial rather than direct. In *Drosophila*, genetic and molecular techniques have defined the causative role of the recessive oncogene *lethal (2) giant larvae* in tumorigenesis[4,5]. Until now, however, comparable studies of dominant oncogenes have been limited to tumour viruses and tissue- and organ culture. Here we describe a genetic system, melanoma formation in the fish *Xiphophorus*, which allows the study of the induction and progression of malignant melanoma in vertebrates. We used this system to clone and characterize the dominant tumour-inducing gene, which we show encodes a novel putative receptor tyrosine kinase (RTK) of epidermal growth factor (EGF)-receptor type.

Genetics of melanoma formation

The platyfish (*Xiphophorus maculatus*) and the swordtail (*Xiphophorus helleri*) have a uniform grey body colouration due to small black pigment cells ('micromelanophores'). Some platyfish, however, exhibit spot patterns of melanophores that are much larger than normal ('macromelanophores')[6]. In hybrid offspring that result from the mating of spotted platyfish with non-spotted swordtails, these macromelanophore spots develop into malignant melanomas[6-8]. Genetic analyses showed that this tumour formation depends on the abnormal regulation of a single genetic locus, the macromelanophore locus of the platyfish in hybrids[9-12]. Further genetic studies led to a model for this melanoma development[13], in which a dominant tumour gene *Tu* (equated with the macromelanophore locus) is under the control of a regulatory gene *R* which acts as a tumour suppressor. The gene *Tu* is located on sex chromosomes, whereas *R* is located on an autosome[14,15]. In the platyfish both *Tu* and *R* are present, but they are both presumed to be absent in the swordtail. The concerted action of *Tu* and *R* results in non-proliferating macromelanophore spots. A variety of spot patterns have been identified in wild-type fish[16], and the corresponding gene loci are accordingly named *Tu-Sd* (spotted dorsal pattern), *Tu-N* (nigra pattern), *Tu-Sr* (striped pattern), and so on. These loci are located either on the platyfish X or Y chromosome. In this report we mainly look at the *Tu-Sd* locus, which maps to the X chromosome. Serially repeated backcrossing of *Tu-Sd*-bearing platyfish to swordtails results in the progressive replacement of *R*-bearing platyfish chromosomes by *R*-free swordtail chromosomes (Fig. 1*a*). The stepwise elimination of regulatory genes is thought to lead to a corresponding stepwise deregulation of *Tu*. This leads to either benign melanoma if only one functional allele of *R* remains, or to malignant melanoma if *R* is totally absent (for review see ref. 17).

Mapping of a marker to the *Tu–Sd* gene locus

The *Tu-Sd* locus has been mapped relative to several other known loci on the X chromosome of the platyfish as follows: cen-*P*-1%-*Ir*-(*Pt-Dr*)-0.03%-(*Tu-Sd*)-ter, where the physical distance between the loci is represented by the recombination fraction (%) between them, as indicated (see refs 16, 18–20, and our own unpublished data). We have previously identified a restriction fragment length polymorphism (RFLP)[21], with limited sequence similarity to a v-*erb-B* gene probe, as a diagnostic marker for sex chromosomes bearing *Tu*. We have cloned a fragment[22] of the corresponding RFLP sequence of the platyfish and used it for Southern blot analyses. DNA digested with *Eco*RI gave an invariant band of 7.0 kilobases (kb), which we have called INV, in all platyfish, swordtails and their hybrids tested ($n = 135$), regardless of the presence or absence of a *Tu* locus. For fish with the X-chromosomal *Tu-Sd* locus ($n = 84$) an additional 5.0 kb band was detected, whereas for fish with the Y-chromosomal *Tu-Sr* locus ($n = 6$), a 6.5 kb band was detected in addition to the 7.0-kb band (Fig. 1*b*).

To further define the linkage between the *Tu-Sd* locus and the 5.0 kb RFLP marker, we analysed backcross (BC) hybrids of platyfish and swordtails for segregation; swordtails were used as the recurrent parent (BC_4-BC_7, crossed as in Fig. 1*a*). No recombination between the 5.0 kb RFLP marker and the *Tu-Sd* locus was observed for all 117 fish tested (Table 1). Both markers, therefore, map on the X chromosome of the platyfish with a maximal separation of 0.85 centimorgans (a recombination fraction of 1% between loci indicates a physical map distance of 1 centimorgan). Our data therefore localize the 5.0 kb marker to the *Tu-Sd*-containing region of the X chromosome. Whereas

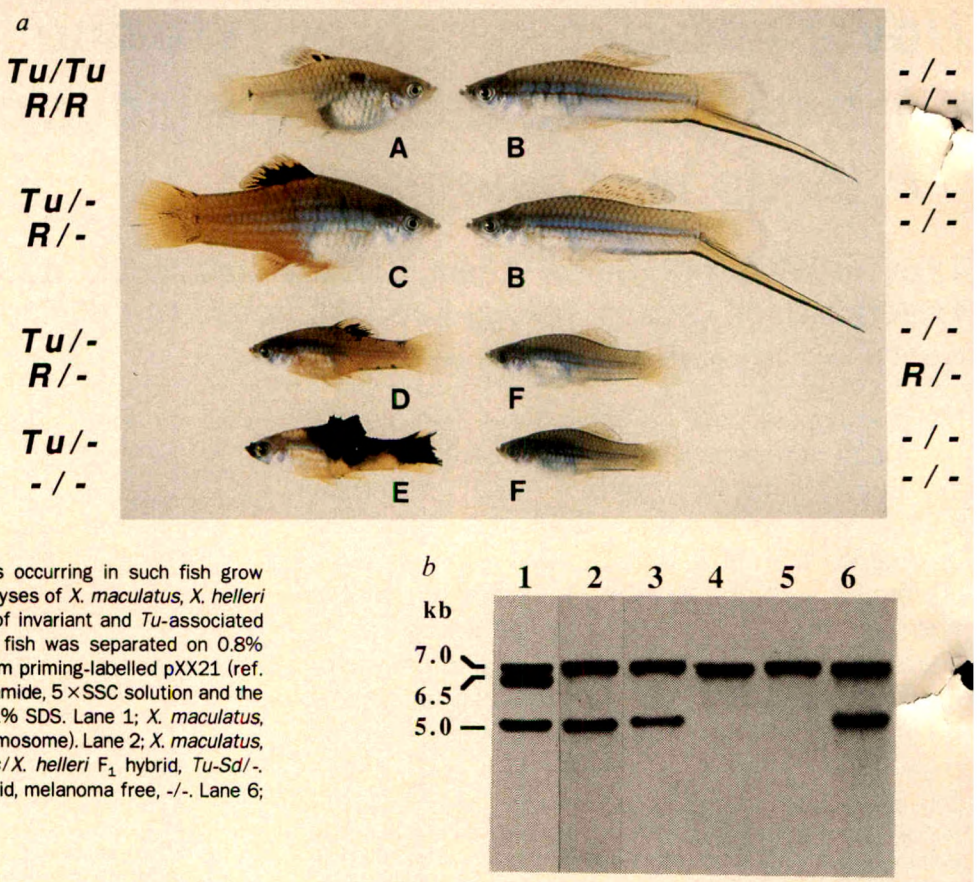

FIG. 1 *a*, Crossing scheme of platyfish (*X. maculatus*) and swordtails (*X. helleri*) with the corresponding *Tu*/*R* constellations (see text). A female *X. maculatus* (A) homozygous for the X-chromosomal macromelanophore *Tu-Sd*-gene (spotted dorsal, small spots in the dorsal fin) is mated to *X. helleri* (B), which does not carry the corresponding locus and exhibits the uniform wild-type pigmentation. The heterozygous F_1 hybrid (C) shows enhancement of the spotted dorsal phenotype. Backcrossing of the F_1 hybrid to *X. helleri* results in offspring, 50% of which have not inherited the *Tu-Sd* locus and are phenotypically like the *X. helleri* parental strain (F), and 50% of which carry the macromelanophore locus and develop melanoma. The malignancy grade ranges from very benign in some individuals (D) (phenotype like the F_1 hybrids), to highly malignant in other individuals (E). Highly malignant melanomas occurring in such fish grow invasively and are fatal. *b*, Southern-blot analyses of *X. maculatus*, *X. helleri* and their hybrids for segregation analyses of invariant and *Tu*-associated RFLP loci. *Eco*RI-digested DNA from single fish was separated on 0.8% agarose gels, blotted and probed with random priming-labelled pXX21 (ref. 22). Hybridization was at 42 °C in 50% formamide, 5 × SSC solution and the filters were washed at 68 °C in 0.1 × SSC, 1% SDS. Lane 1; *X. maculatus*, male, *Tu-Sr* (Y-chromosome)/*Tu-Sd* (X-chromosome). the invariant 7.0-kb sequence is present in all fish, the *Tu-Sd*-specific 5.0 kb sequence seems to be an additional genomic constituent of fish that have the *Tu-Sd* gene locus. By analogy we conclude that the 6.5 kb marker can be assigned to the *Tu-Sd*-containing region of the platyfish Y chromosome (Fig. 1*b*).

Cloning of the *Tu*-linked RFLP sequences

To clarify the relationship of the RFLP sequences to *Tu*, the invariant (INV), Y chromosomal (Y) and X chromosomal (X) *Eco*RI restriction fragments were cloned from a sub-genomic library of male platyfish (X^{Tu-Sd}/Y^{Tu-Sr}). The corresponding partial complementary DNAs, incomplete for the 5′ end of the gene, were isolated from two separate cDNA libraries. The first library was generated from a melanoma that had arisen because of the presence of the X-chromosomal *Tu-Sd* locus, and the second library from a cell line (PSM; ref. 23) derived from a melanoma that had arisen because of the presence of a Y chromosomal *Tu* locus. To obtain the entire sequence of one of the cDNAs we used oligonucleotides for preparation of a primer extension library. A 2.4-kb clone, which overlapped the 1.7-kb PSM clone by 98 nucleotides, was isolated and found to contain the missing 5′ sequence. The sequencing of the three genomic *Eco*RI fragments and their comparison with the cDNA sequences revealed that each genomic clone contained the 3′ portion of the same gene (Fig. 2*b*, *c*). Despite a high degree of sequence conservation throughout the exons and the introns (99%) as well as their common arrangements and sizes in homologous regions, several structural differences confirmed the independent nature of the three clones and allowed their assignment to the individual cDNAs. The three *Eco*RI fragments are therefore regarded as deriving from three different genomic loci. Although all the three loci have almost identical restriction-site maps upstream of the *Sac*I site (at nucleotide 1,915) their physical maps downstream of this position differ. Most striking are the additional sequences in the loci of the INV fragment and the Y fragment of 1,349 and 1,395 bp, respectively (Fig. 2*b*). These additions contain intron sequences, exon y and the first five nucleotides of the large 3′ exon (exon z) encoding the trailer region. These sequences are deleted from the X chromosomal locus. The cDNA clone from a melanoma that contained the X-chromosomal *Tu-Sd* locus, lacked exon y as expected, whereas the Y-chromosomal cDNA did not (Fig. 2*c*); this confirmed the genomic locus arrangement. The amino-acid sequence predicted from the X-chromosomal cDNA sequence indicated that the deletion does not change the reading frame, and thus represented a polypeptide with an internal deletion of 35 amino acids (see below). Neither cDNA extended to the poly(A) tail, although all three genomic loci contain a polyadenylation-site signal at corresponding positions. This would add another 229 nucleotides downstream of the cDNA sequence (Fig. 3).

TABLE 1 Segregation of *Tu-Sd* and the 5.0 kb marker sequence

			n
Parental class 1	*Tu-Sd*	5.0-kb RFLP marker	76
Parental class 2	+	+*	41
Recombinant class 1	*Tu-Sd*	+	0
Recombinant class 2	+	5.0-kb RFLP marker	0
		Total = 117	

* The 5.0-kb *Eco*RI fragment is additional to the invariant 7.0-kb fragment of wild-type fish, therefore lack of the 5.0-kb RFLP marker is regarded as the wild-type situation (+).

RFLPs are a structural component of the *Tu* locus

That the sex-chromosomal genes are actually encoded by the *Tu* locus is shown by the presence of 'loss of function' *Tu* alleles. We analysed two spontaneous *Tu* mutants that do not exhibit a single macromelanophore and have lost the capacity to develop malignant melanoma in backcross hybrids. In one mutant

derived from the Y-chromosomal *Tu-Sr* locus, the 6.5-kb fragment is totally-deleted (Fig. 2*d*). In another mutant, a rearranged *Eco*RI fragment of 12 kb instead of the expected 5.0 kb, in addition to the invariant 7-kb fragment, was detected with the RFLP probe (Fig. 2*d*). Because we have so far detected no intra-strain polymorphism for the X- or Y-chromosomal marker sequences (see Table 1, ref. 21, and unpublished data) this 12-kb fragment was cloned and analysed. Restriction mapping and sequence analysis precisely defined an insertion of ~7 kb between base-pairs 1,652 and 1,653 in exon w (Fig. 2*e*). This insertion, therefore, interrupts the coding sequence of the X-chromosomal gene. The result of this alteration is the loss of the *Tu*-phenotype. We conclude therefore that the X-chromosomal 5.0-kb marker sequence is the 3′ part of the *Tu-Sd* gene locus, the Y-chromosomal 6.5-kb marker by analogy is the homologous part of *Tu-Sr*, whereas the 7.0-kb marker represents a gene found in all fish independent of sex-chromosomal *Tu* loci.

A novel putative receptor tyrosine kinase

The almost full-length cDNA clone isolated from the PSM cell line contains a single long open-reading frame (ORF) of 3498 nucleotides, which starts with ATG and terminates with an

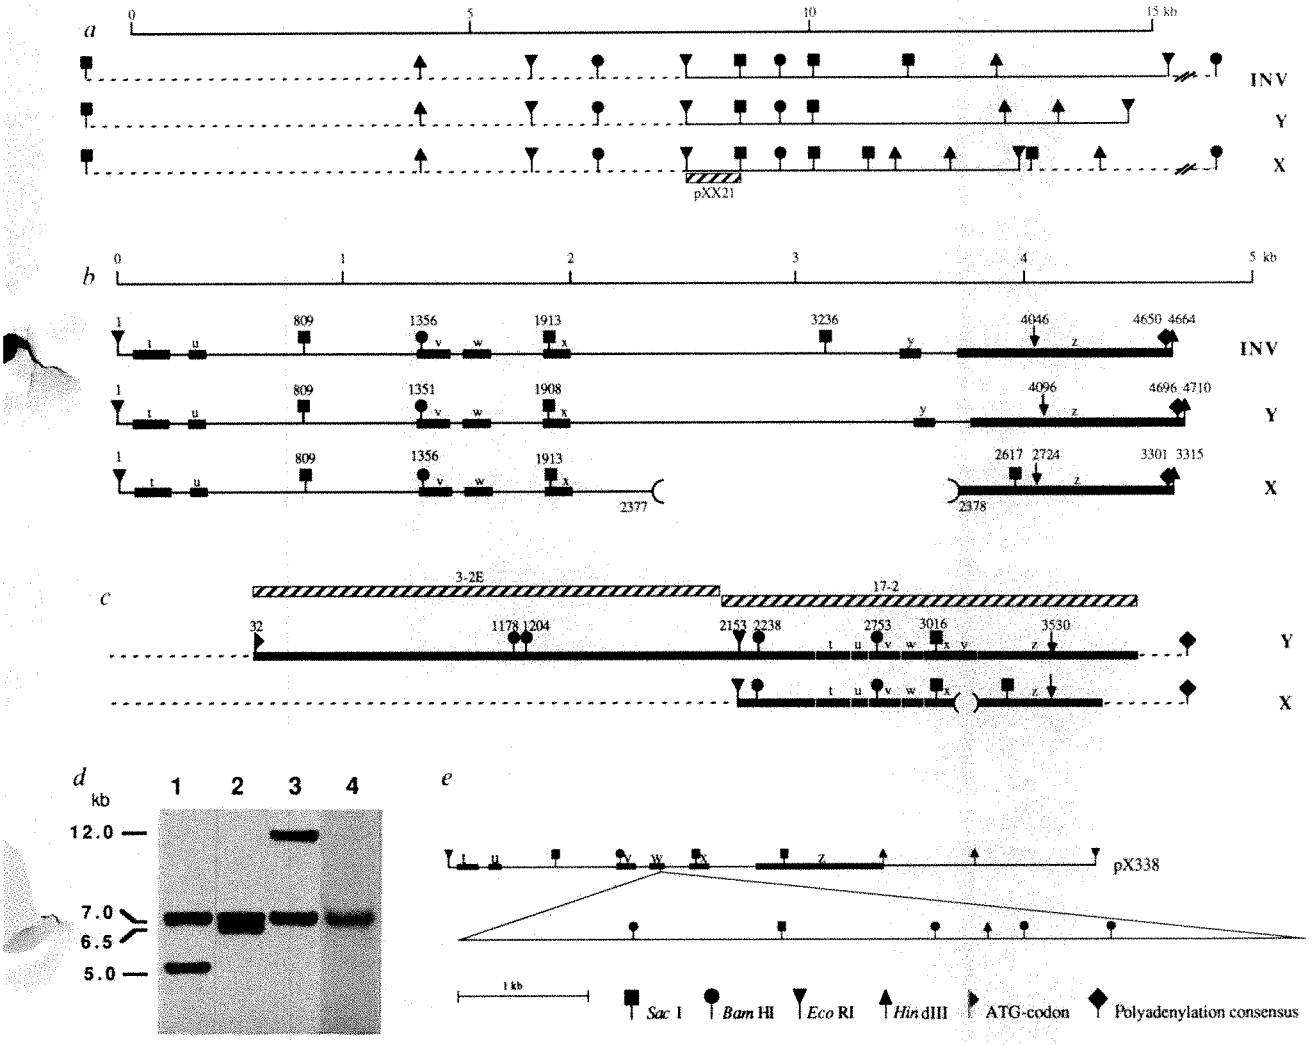

FIG. 2 Partial structure of the genomic region of INV-, Y- and X-linked RFLP loci and corresponding cDNAs. *a*, Restriction map of the genomic loci. *b*, Exon–intron arrangements in the 3′ region of INV-, Y- and X-genomic loci. Differing positions of exons, stop codons, restriction sites and polyadenylation consensus sites downstream of nucleotide 1,277 between INV-, X- and Y loci result from sequence differences in the corresponding trailer and intron regions. *c*; Comparison of X- and Y-loci transcripts. Sequenced cDNAs are marked in black. *d*; RFLP analysis of the loss-of-function mutants. Southern-blot analysis of *Eco*RI-digested DNA of *X. maculatus*/*X. helleri* BC hybrids (recurrent parent *X. helleri*) carrying the parental wild-type *Tu-Sd*-bearing X chromosome (BC_7, lane 1), *Tu-Sr*-bearing Y chromosome (BC_2, lane 2) and the two independent mutant chromosomes (BC_2, lanes 3 and 4). For methods see Fig. 1. *e*; Restriction map of the rearranged 12-kb fragment from the loss-of-function mutant (see Fig. 2*d*, lane 3). Relevant stop codons are marked by arrows; deleted fragments are bounded by semi-circles; cloned fragments are indicated by solid lines; structural data obtained by Southern- or Northern-blot hybridizations are shown by broken lines; probes used for screening shown by hatched boxes.

METHODS. INV-, Y- and X-linked fragments were cloned as follows: High molecular weight genomic DNA from male *X. maculatus* (stock Rio Jamapa X^{Tu-Sd}, Y^{Tu-Sr}) was prepared by standard methods[41]. The DNA was digested to completion with *Eco*RI. Fragments were separated on a LMP-agarose gel. Gel fractions with sizes of ~5 kb, 6.5 kb and 7 kb were cut out; purified DNA was ligated into λgt10 arms and packaged. The sub-libraries were screened with a v-*erb* B probe (600-bp *Bam*HI fragment D of pAE11 ref. 42) as well as with pXX21 (ref. 22). Hybridization conditions were 42 °C, 40% formamide, 5×SSC (wash at 60 °C, 2×SSC) for pAE11, and as described in Fig. 1 for pXX21. Genomic *Eco*RI–*Hin*dIII sub-fragments of INV, Y and X and the corresponding cDNAs were subcloned into pBluescript (Stratagene). For cloning of the 12-kb fragment from the loss-of-function mutant, DNA from a BC_2 hybrid containing the mutant chromosome was cloned as outlined above into λEMBL4. The subgenomic library was screened with the 17–2 the probe (Fig. 2*c*) under high stringency conditions. Sequencing: nested deletions were generated using either Exonuclease III (ref. 43), or T4 DNA polymerase[44] (using oligonucleotides adapted for pBluescript). Sequences were determined by dideoxy chain-termination sequencing using Sequenase (US Biochemical Corporation) or T7 DNA polymerase (Pharmacia). Sequence analysis was performed using the GCG sequence analysis software package[45].

amber codon (Fig. 3). The deduced amino-acid sequence corresponding to this ORF is a polypeptide of 1,166 amino acids with a predicted relative molecular mass of 130,000 (Fig. 3). This hypothetical protein has two strongly hydrophobic regions (Fig. 3). One of these regions at the N terminus of the protein exhibits several features typical of signal peptides[24]. A possible cleavage site in the uncleaved peptide for signal peptidase, deduced from the $-3/-1$ rule[25], is after residue 25. There is a second strongly hydrophobic region, of 23 amino acids, between residues 618 and 640 of the cleaved peptide. By the criteria of Klein *et al.*[26], this segment has a high probability of spanning a membrane. It is preceded by a positively charged histidine and is followed by four positively charged arginines that could serve as a transfer-stop signal. These features of the primary structure indicate that the protein traverses a cellular membrane and is therefore comprised of an extracellular domain of 617 amino acids, a single transmembrane domain of 23 amino acids and a cytoplasmic domain of 501 amino acids. There are 12 putative glycosylation sites, all located in the hypothetical extracellular domain of the protein (Fig. 3). Comparison of the predicted polypeptide sequence with sequence data-banks indicates that this polypeptide has significant similarity with receptor tyrosine kinases (RTKs), most markedly with the human EGF-receptor[27]. All other RTKs such as the insulin receptor, the insulin-like growth-factor receptor, the platelet-derived growth factor (PDGF) receptor, and those encoded by *HER2/neu* and

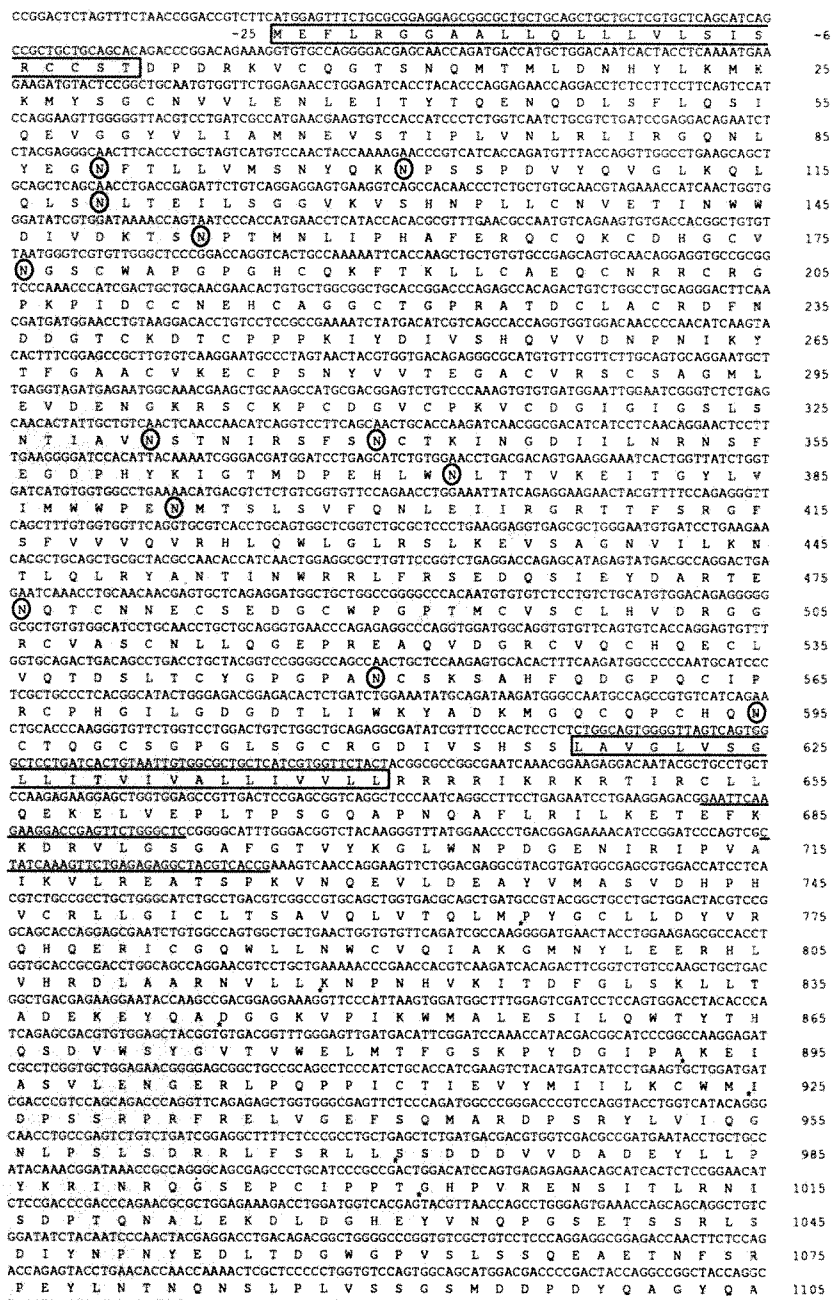

FIG. 3 Nucleotide sequence of the *Tu* gene and the predicted protein sequence. (Single letter amino acid code.) The nucleotide sequences (numbered left) of the overlapping cDNA clones 3–2 and 17–2 are in upper case. The sequence of the 3′ end of exon z, which is not represented in the cDNA is derived from genomic DNA and shown in lower case. The predicted amino-acid sequence (numbered right) is shown below the nucleotide sequence. Potential glycosylation sites (N-X-(S/T)-X) are circled. The hydrophobic leader peptide (residues −25 to −1) and transmembrane domain (residues 618–640) are boxed. Oligonucleotides complementary to the sequences underlined were used for generation of a specifically-primed cDNA library (nt 2,281–2,250) and screening (nt 2,181–2,153), respectively. The putative polyadenylation signal at the 3′ end is underlined. Exon boundaries derived from the genomic sequences are indicated by an asterisk (see also Fig. 2).

METHODS. An oligo(dT)-primed cDNA library was prepared by standard methods from the melanoma cell line (PSM) poly(A)$^+$ RNA. The library was screened with random priming-labelled v-*erb* B probe (600-bp *Bam*HI fragment D of pAE11; ref. 42) and pXX21 (ref. 22) under the conditions described in Fig. 2. The specifically-primed library was prepared from total RNA of PSM cells using an oligonucleotide complementary to nt 2,281–2,250 (see above). After denaturation of the RNA and pre-annealing of the oligonucleotide a cDNA-kit (Pharmacia) was used for preparation of double-stranded cDNA. Following ligation to λ, t10 arms, the DNA was packaged with Gigapack plus (Stratagene). The library was screened with a ^{32}P-labelled oligonucleotide complementary to nt 2,181–2,153 (see above). Generation of nested deletions and sequencing was performed as in Fig. 2.

c-*kit*, were significantly less similar. Like the EGF receptor, the *Tu*-encoded polypeptide is preceded by a signal peptide (25 amino acids compared with 24 amino acids in EGF receptor). In both proteins the extracellular domain is composed of two cysteine-rich domains. Most cysteine residues (all 24 in domain I, 19 of 21 in domain II) in the domains of the EGF receptor are conserved between the two proteins (Fig. 4*a*). As with the EGF receptor, the *Tu*-encoded protein contains a single transmembrane domain, followed by a cytoplasmic juxtamembrane domain of 41 amino acids. The amino acids in this region are very highly conserved when compared with those of the corresponding region of the EGF receptor (95% similarity), including Thr 654 of the EGF receptor, which is a target for protein kinase C phosphorylation[28]. The remaining C-terminal portion of the predicted protein shows all the structural features of a functional tyrosine-kinase domain. All diagnostic structural motifs are conserved[29]. The C-terminal tail is less well-conserved on comparison with that of the EGF receptor and is heterogeneous in the predicted proteins encoded by the X- and Y chromosomes (see above). The Y-chromosomal C-terminus consists of 193 amino acids compared with 158 amino acids for the X-chromosomal C-terminus and 235 for the EGF receptor. The Y-chromosomal *Tu*-encoded protein contains three tyrosine residues in the 3′ domain which, by analogy for the EGF receptor, may serve as auto-phosphorylation sites (Fig. 4*a*), whereas the X-chromosomal *Tu*-encoded protein lacks the tyrosine residue corresponding to Tyr 1068 of the HER (human EGF-receptor) because of the in-frame deletion (see above).

We suggest, therefore, that the *Tu* oncogene encodes a transmembrane RTK with high similarity to the EGF receptor of higher vertebrates. We have called this gene *Xmrk* (*Xiphophorus* melanoma receptor tyrosine kinase).

Does *Xmrk* represent the fish EGF-receptor gene or is it a novel member of the subclass I RTK gene family, so far known to comprise the genes encoding the human, chicken and *Drosophila* EGF receptors (HER, CER and DER, respectively) and *HER2/neu*[30]? Sequences that hybridize most strongly with the v-*erb-B* probe have been isolated from a *Xiphophorus* genomic library and have been further characterized. In the central portion of the tyrosine-kinase domain, for which sequence information is available from the gene that encodes the *Xiphophorus* EGF-receptor (XER), there are motifs that the

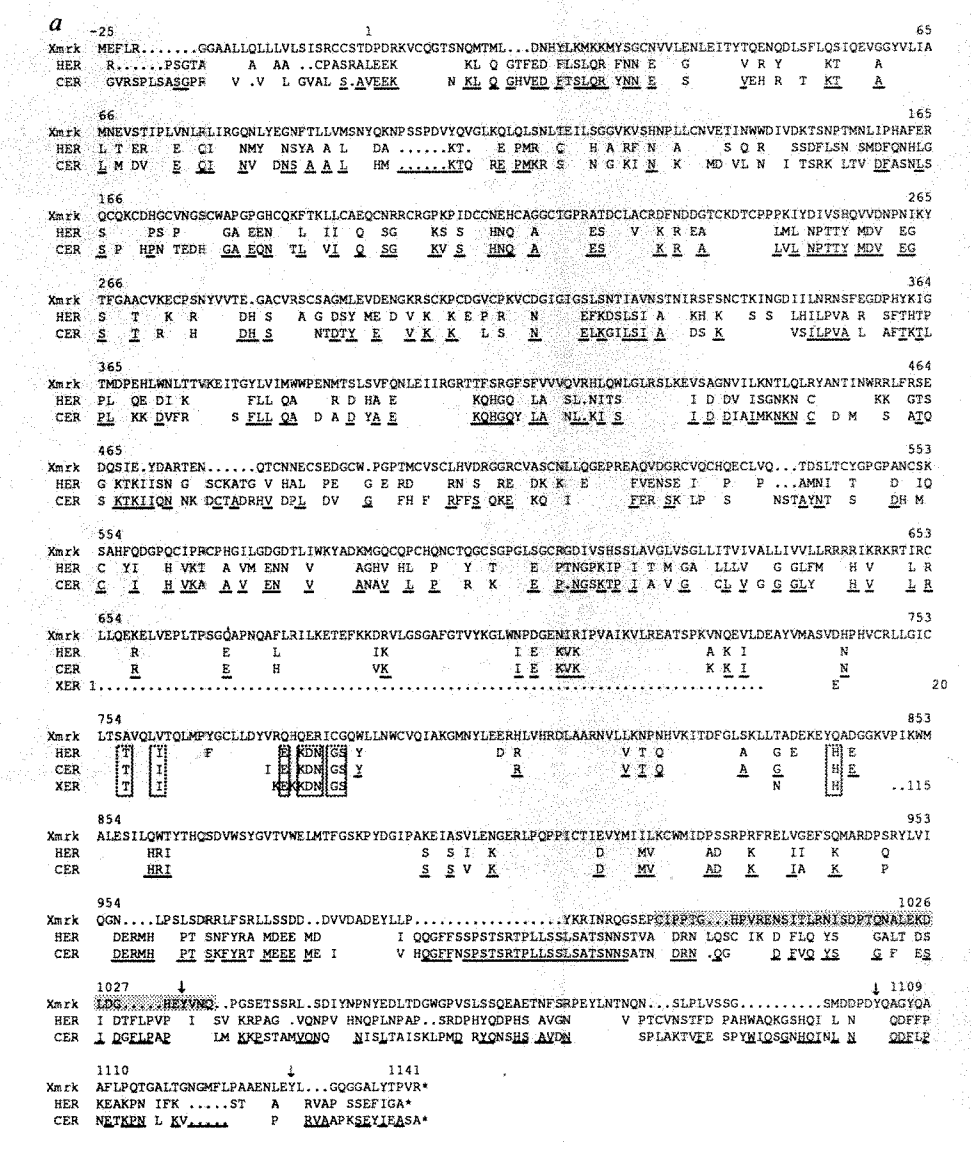

FIG. 4 Comparison of the *Xmrk*-gene product with human EGF receptor (EGF-R)[27], chicken EGF-R[46] and the *Xiphophorus* EGF receptor homologue (partial), and structural organization of the predicted *Xmrk*-encoded protein. *a*, Amino-acid sequence comparison (single-letter code): Residues identical between all proteins are shown only in the *Xmrk* line. Residues identical in human EGF-R and chicken EGF-R but different in the *Xmrk*-gene product are underlined; residues identical in human EGF-R, chicken EGF-R and *Xiphophorus* EGF-R but different from the *Xmrk*-encoded protein are boxed. The residue predicted to be the first in the mature protein is numbered 1. The deletion in the predicted C-terminus of the X-chromosomal *Xmrk* gene product is shaded. Tyrosine residues homologous to Tyr 1,068, Tyr 1,148 and Tyr 1,173 of the HER are marked by arrows. (asterisk, translation stop site) *b*, Structural organization of the *Xmrk*-encoded protein. Different domains of the predicted protein are presented schematically: the hydrophobic signal peptide (SP) and transmembrane domain (TM) are in black; the two cysteine-rich modules of the extracellular domain (II, IV) are hatched; the tyrosine-kinase domain (TK, subdomains I–XI according to ref. 29) is cross hatched. Similarity values shown above the domains are based on the amino-acid sequence comparisons in Fig. 4*a* for *Xmrk*-gene product compared with human EGF-R.

XER protein has in common with the HER- and the CER proteins that are not common to the *Xmrk*-encoded protein (Fig. 4*a*). Within this region, *Xmrk* has only 76% identity to the gene that encodes XER, and the two proteins that these genes encode have 83% identity. Sequence comparisons shows that the chicken and human EGF-receptor proteins have extended motifs in common throughout their extracellular domains and C-terminal tails, which are divergent from the corresponding sequences predicted for the *Xmrk*-encoded protein (Fig. 4*a*). The *Xmrk*-encoded protein is not therefore, the fish EGF-receptor homologue, but a novel putative receptor tyrosine kinase.

Elevated expression in melanoma

To investigate the physiological function of *Xmrk* we studied its expression pattern during embryogenesis, in normal adult tissue and in melanomas, induced by sex-chromosomal *Tu* loci, that differ in their degree of malignancy. Northern-blot hybridizations of RNA obtained from swordtail embryos containing only the INV *Xmrk* locus revealed a single *Xmrk* transcript of 5.8 kb (Fig. 5*a*). This transcript was highly abundant as a maternal messenger RNA in unfertilized eggs (Fig. 5*a*, lane 1). The level decreased during early development (cleavage to neurula stages), increased during organogenesis and from then on decreased. In 4-week-old neonate fish, only barely detectable hybridization signals were obtained (Fig. 5*a*, lane 10). In normal organs of adult fish the transcript was seen at low levels in gills, fins and skin but not in any other organ tested (data not shown).

In all melanomas that originated from six different *Tu* alleles from hybrid fish and in the melanoma cell line (PSM)[23], high levels of *Xmrk* transcripts were found (Fig. 5*b*). The RNA preparations included both early- and late-onset melanomas[23], as well as amelanotic tumours from fish homozygous for the albino (*a*) gene. Two large transcripts were seen, one that corresponds in size to the transcript from the INV locus (5.8 kb; see above) and a smaller transcript (4.7 kb) which is specific for the melanoma (Fig. 5*b*). Shorter transcripts (less than 3 kb) represented either specific degradation products, or transcripts of different length, but from the same gene, generated by differential splicing, alternative transcription start sites or alternative polyadenylation signals. The steady-state level of the 4.7 kb mRNA and the shorter transcripts was highly correlated to the the degree of malignancy of the melanoma. This was most obvious for tumours due to the *Tu-Sd* allele, for which backcross genotypes of defined malignancy were available. In extremely benign lesions, which occur in the presence of one intact allele of the melanoma suppressor gene *R*, only very low amounts of *Xmrk* mRNA were seen (Fig. 5*c*, lane 9) compared with the amounts seen in more malignant melanoma from fish that lacked both alleles of *R* (Fig. 5*c*, lane 10). In addition, fish that were heterozygous for *a*, which further enhances melanoma malignancy, had even higher transcript levels (Fig. 5*b*, lane 11). Expression of the INV locus was at a similarly low level in all tumours irrespective of their state of malignancy. The observation of a 5.8 kb INV *Xmrk* transcript in several normal tissues and the absence of the tumour-specific 4.7 kb transcripts indicates that the INV locus bears the *Xmrk* proto-oncogene.

Discussion

We have made use of the *Xiphophorus* melanoma system to study malignant tumours by both genetic and molecular techniques. We have cloned the oncogene *Tu* of *Xiphophorus*, known to induce malignant melanoma in the absence of the anti-oncogene *R*, and found that it encodes a novel transmembrane tyrosine kinase. We have called this gene *Xmrk*. In addition to the oncogenic *Xmrk* loci on the X- and Y chromosomes of platyfish, we found that another copy of *Xmrk* at the INV locus is a normal constituent of the genome of all *Xiphophorus* fish, independent of the melanoma oncogene. This copy is probably the *Xmrk* proto-oncogene, which could have a normal physiological function during development and in specific tissues.

The proposed structure of the protein encoded by *Xmrk* and its similarity to the subclass I growth-factor-receptor tyrosine kinases indicates that it is a transmembrane protein with an extracellular domain acting as a receptor, and a cytoplasmic tyrosine-kinase domain. RTKs are normally activated by the binding of a specific ligand which results in the phosphorylation of specific cellular proteins, thus producing a pleiotropic response, including proliferation and/or differentiation[28]. It is probable that *Xmrk* participates in such a signal-transduction mechanism. Although the predicted protein encoded by *Xmrk* shows structural similarity to the EGF-receptor of higher vertebrates, our data show that it does not represent the fish EGF-

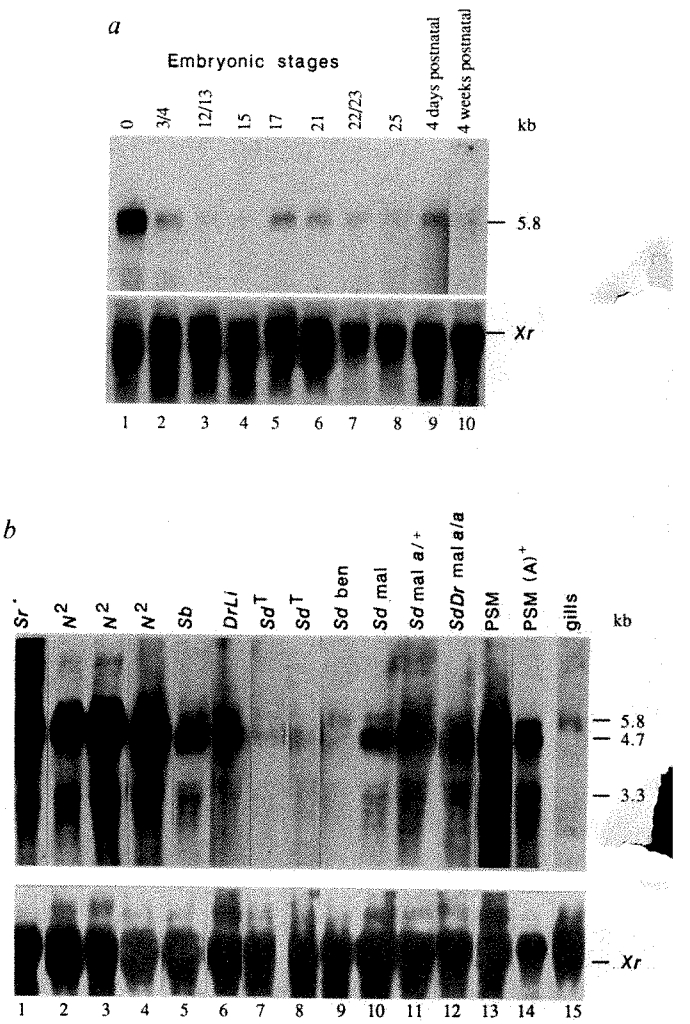

FIG. 5 Northern-blot analyses. *a*, Profile of *Xmrk* expression during embryonic development (for staging see ref. 47) (lanes 1–8), and at two different postnatal times (lanes 9 and 10) in fish containing only *Xmrk* at the INV locus. In each case, 20 μg of total RNA was analysed by Northern-blot hybridization. *b*, *Xmrk* expression in melanomas and in gills (lane 15). Total RNA (20 μg) from single tumours (lanes 1–4, 6, 11) or pooled melanoma biopsies (lanes 5, 7–10, 12) and a melanoma cell line (lanes 13 and 14) were analysed. PSM, melanoma cell line; *a*, albino gene; ben, benign; mal, malignant; all other abbreviations refer to melanomas due to different *Tu* alleles (lanes 1–5, Y-chromosomal; lanes 6, 9–12, X-chromosomal; lanes 7, 8, autosomal); *Sr"*, *mutant striped*; N^2, nigra-2; *Sb*, spotted belly; *DrLi*, mutant lineatus; Sd^T, spotted dorsal translocation; *Sd*, spotted dorsal.
METHODS. RNA preparation, Northern blots and hybridizations for homologous probes were performed as described [38]. Probes used were random-priming-labelled 17-2 DNA (*b*) or a riboprobe of 17-2 (*a*). For size calibration a RNA ladder (BRL, Bethesda) was included. As a control for the amount of RNA blotted onto the membranes, the ubiquitously expressed *Xr* gene[48] was used as a hybridization probe.

receptor. The *Xmrk*-protein therefore, probably does not bind the fish EGF homologue. The *HER2/neu* gene product, which so far in mammals is the most closely related protein to the EGF-receptor, does not recognize EGF as its physiological ligand but binds to an as yet unidentified molecule[31-33]. Further experiments are needed to identify the possible ligand of the *Xmrk*-gene product RTK.

No satisfactory candidate for a RTK substrate has been identified[30]. The normal physiological function of the *Xmrk* encoded RTK is therefore beyond speculation, although the abundant *Xmrk* maternal message is intriguing with regard to recent reports that RTKs, like the *Drosophila* EGF-receptor and the *torso*-gene product, function as maternal-effect genes during early embryonic development[34-36].

The existence of the sex-chromosomal oncogenic *Xmrk* loci as additional genomic constituents in the platyfish poses the question of their evolutionary origin. It is conceivable that an allelic or duplicated copy of the INV-locus *Xmrk* gene was translocated to the sex-chromosomal pigmentary loci thereby acquiring an oncogenic potential. This is supported by the identification of macromelanophore pigment patterns in several poeciliid fish species and even in the genus *Xiphophorus* that never give rise to tumour formation after the hybridization (ref. 10, and our own unpublished data). In purebred platyfish the malignant phenotype is suppressed because of the presence of the *R* gene. After crossing-conditioned elimination of the *R* gene, melanoma develops. We have shown that the steady-state levels of sex-chromosomal *Xmrk* transcripts correlate with the genetically determined malignancy of the tumour, raising the possibility that transformation is affected by an increase in the level of *Xmrk* transcription. Such a situation is reminiscent of c-*myc* activation in Burkitt's lymphoma (reviewed in ref. 37) in which inappropriate regulation of *myc* is a consequence of a translocation.

Over-expression of RTKs of subclass I in tissue-culture leads potentially to oncogenesis, and increased levels are frequently, associated with certain human malignancies (for a review see ref. 30). It should be noted, however, that in these tumours increased expression is mostly due to gene amplification, whereas in *Xiphophorus* melanomas no evidence for an amplification of *Xmrk* or related genes was obtained[21,38]. Recent studies indicate that in addition to over-expression of RTKs (in conjunction with autocrine ligand production), structural alterations may have a key role in the initiation as well as the progression of certain neoplasms (for a review see ref. 30). The *Xmrk* melanoma-specific transcripts are ~1 kb shorter than the transcript from the proto-oncogenic *Xmrk* at the INV locus. This points to such a structural alteration, possibly associated with the proposed translocation event. The full significance of the differing transcripts awaits further elucidation. The C-terminal deletion observed for the *Xmrk*-gene products encoded by the X-chromosomal locus seems not to affect its transforming capability in general, because in this region the potentially oncogenic *Xmrk* at the Y-chromosomal locus contains an identical exon as the proto-oncogenic *Xmrk* at the INV locus. This difference, however, may account for an observed variability in the malignancy of the resulting melanoma; the X-chromosomal *Tu-Sd* locus is responsible for much more severe tumourous lesions than the Y-chromosomal *Tu-Sr* locus. For the subclass I RTKs of higher vertebrates, a variety of minor or severe alterations of the C-terminal domains do not alter transforming potentials in general, but confer higher sensitivity to ligand-induced mitogenesis than that found in the wild-type situation[39,40] (for a discussion see ref. 30).

We propose that the melanoma oncogene of *Xiphophorus* encodes an activated version of a novel putative RTK, whose oncogenic potential is suppressed in wild-type platyfish. The suitability of fish for developmental biological studies and the availability of numerous mutants and wild-type alleles that affect the melanoma oncogene itself (or the phenotype of the resulting melanoma) makes *Xiphophorus* a unique *in vivo* system for studies of RTK-mediated oncogenesis as well as possible mechanisms for the suppression of this process. □

Anisotropic ionizing radiation in NGC5252

Clive Tadhunter* & Zlatan Tsvetanov†

* Royal Greenwich Observatory, Madingley Road, Cambridge CB3 0EZ, UK
† European Southern Observatory, Karl-Schwarzschild-Strasse-2, D-8046, Garching bei München, FRG

THE different kinds of active galactic nuclei (AGNs) and quasars may be fundamentally similar, and owe their observed differences to anisotropy in the distribution of their emitted radiation: apparently different objects may then be the same thing seen from different viewpoints. In particular, it has been proposed that narrow-line Seyfert 2 galaxies are Seyfert 1 galaxies for which the broad-line and continuum emitting regions are hidden by obscuring material along our line of sight[1,2]. Here we present narrow-band imaging observations of the Seyfert 2 galaxy NGC5252 which strongly support such unifying hypotheses. Images in the light of the [O III] line at $\lambda = 5{,}007$ Å reveal a sharply defined bi-conical structure extending to a maximum radius of ~33 kpc ($H_0 = 50$ km s^{-1} Mpc^{-1}) along the radio-emission axis. This is just the type of structure expected if the ionizing-radiation field from the nucleus is anisotropic. A map of the ratio of the [O III] and Hα lines shows a central band perpendicular to the cones that we identify as the disk or torus responsible for collimating the radiation field.

Some of the best evidence that the ionizing continuum is radiated anisotropically by active galactic nuclei is provided by observations of the surrounding extended emission-line regions (EELR). Long-slit spectroscopic and narrow-band imaging observations show that, where the emission lines are extended, they are often more extended along or near the radio-emission axis than in the perpendicular direction[3,4]. Moreover, in many objects the highest ionization EELR are found along the radio-emission axis, and for these one commonly finds that a power-law extrapolation of the observed nuclear continuum is incapable of providing enough ionizing photons to produce the observed emission-line luminosities[4-6]. These results apply across the whole range of radio powers, from the relatively low radio-power Seyfert galaxies to the most powerful radio galaxies and quasars.

Although the link between the collimation direction of the radiation field and the radio axis is clear, the collimation mechanism remains uncertain. Several are possible, including radiation of the continuum emission by an accretion disk, leading to a $\cos\theta$ dependence of the continuum emission on the angle θ to the axis of the disk[7], relativistic beaming[8,9], and simple obscuration of the radiation field by a disk or torus[1,2] of gas and dust.

To examine the anisotropy in more detail we have obtained images and spectra of NGC5252, a Seyfert 2 galaxy which was known from previous observations to have bright emission lines preferentially extended along the radio-emission axis[3]. Some basic properties of NGC5252 are listed in Table 1. The observations were taken using the European Southern Observatory Faint-Object Spectrograph and Camera (EFOSC) on the ESO 3.6-m telescope at La Silla, Chile in March 1989. We report the spectroscopic observations in detail elsewhere (C.T. and Z.T. manuscript in preparation). Here we concentrate on the images that were taken with interference filters ($\Delta\lambda \approx 60$ Å) centred on redshifted positions of [O III], Hα and two line-free continuum bands ($\lambda_c = 5{,}210$ Å and $\lambda_c = 7{,}027$ Å).

A striking aspect of the continuum-subtracted [O III] image (Fig. 1*a*) is the elongated structure extending in a series of shells out to a maximum radius of ~50 arcsec (~33 kpc) to the north and ~45 arcsec (~30 kpc) to the south of the nucleus. This structure is consistent with a bi-conical geometry, with the long axis of the cones roughly aligned with the radio-emission axis. Our long-slit spectra show the EELR within the structure have a high ionization state consistent with photoionization by a continuum with a substantial extreme ultraviolet (EUV) component, but inconsistent with photoionization by normal OB stars[10]. The opening angle of the cones is ~75°. It is just the type of structure expected if the interstellar medium (ISM) in the host galaxy is illuminated by an anisotropic radiation field from the nucleus. As such, it perhaps represents the best example of radiation cones yet seen in Seyfert galaxies.

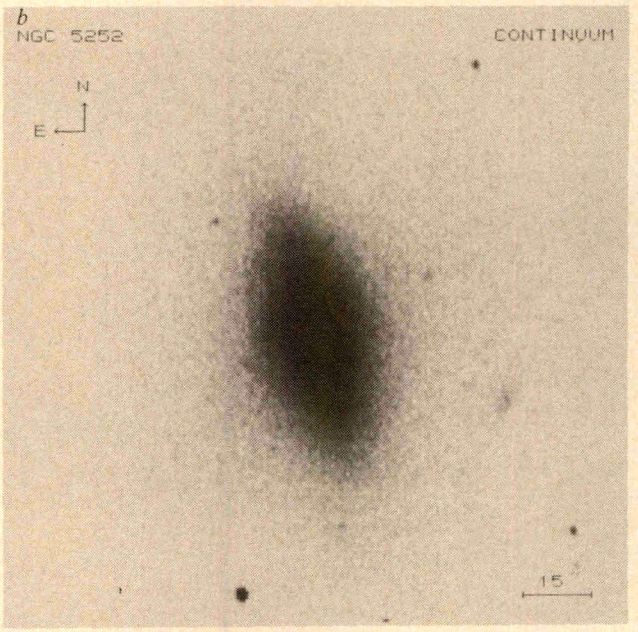
TABLE 1 Basic properties of NGC5252

z	0.0234	
Morphology	S0	ref. 21
M_B (15 arcsec aperture)	−20.4	ref. 15
P_{6cm} (W Hz^{-1} sr^{-1})	3.4×10^{21}	ref. 22
$L_{[O\,III]}$ (erg s^{-1})	1.4×10^{42}	
PA of major axis of the host S0	15°	
PA of [O III]-cone major axis	167°	
PA of central band	75°	
PA of radio-emission axis	170°	ref. 3

In contrast, the continuum image (Fig. 1*b*) reveals a bulge-dominated structure typical of S0 galaxies. The relationship between this and the [O III] cones is unclear because the major axis of the S0 disk (PA ≈ 15°) is misaligned from the cone axis by ~30°. To search for evidence of an ISM associated with the S0 disk we have divided our two continuum images to form a colour map. This shows redder colours in a linear structure parallel to the S0 major axis which are consistent with obscuration by dust in the galaxy disk and therefore provide preliminary evidence that NGC5252 contains an ISM that is not photoionized by the intense component of the nuclear radiation field. The origin of the [O III]-emitting gas—much of which lies outside the galaxy disk and has a shell-like morphology—remains uncertain. Perhaps the most likely explanation is that the shells represent the illuminated sectors of ring structures that surround most of the visible galaxy. This would make NGC5252 similar to several other S0 galaxies for which large-radius ring structures have been observed in H I observations[11].

A clue to the nature of the radiation collimation mechanism is provided by the sharpness of the edges of the emission-line cones (Fig. 1*a*)—such sharp definition would not be expected if the continuum had the tangential dependence predicted for emission from an accretion disk or for relativistic beaming, but it is consistent with obscuration by a disk. Indeed, some evidence for such an obscuring region is apparent in the [O III]/Hα line-ratio map presented in Fig. 1*c*. This shows a band of reduced [O III]/Hα roughly perpendicular to the emission-line cones, which can either be interpreted as a region of higher obscuration or as a region of lower ionization. In either case, the alignment of the band leads us to associate it with the central disk or torus responsible for collimating the radiation field. We note that evidence for a similar band has recently been found for the nearby Seyfert 1 galaxy NGC4151[12]. Interestingly, the major axis of the band is misaligned from the major axis of the host S0 galaxy by ~60°. The position angles of the various components in NGC5252 are compared in Table 1.

Apart from the emission-line structure, we can use the line fluxes derived from our images to test the proposed unification of Seyfert 1 with Seyfert 2 galaxies[1,2]. From simple recombination arguments, the total Hα luminosity ($L_{H\alpha}$) can be related to the monochromatic continuum luminosity that an observer in the cone would infer assuming an isotropic continuum (L_λ). For a power-law optical-to-X-ray continuum ($F_\nu \propto \nu^\alpha$) we have



$$L_\lambda = \left(\frac{-\alpha}{55f(1-\cos(\theta/2))}\right)\left(\frac{\lambda}{\lambda_0}\right)^{-(2+\alpha)} L_{H_\alpha} \qquad (1)$$

where f is the fraction of ionizing photons in the cones that are absorbed by the gas, λ_0 is the wavelength of the Lyman limit,

θ is the opening angle of the cones and Case B recombination for an electron temperature of 15,000 K has been assumed. Our images give $L_{H_\alpha} > 3.3 \times 10^{41}$ erg s^{-1}, after making a 50% correction for [N II] emission in the filter bandpass. Substituting this into the equation with $f = 1$ and the appropriate value of θ we obtain $L_{4,400\,\text{Å}} > 6 \times 10^{39}$ erg s^{-1} Å^{-1} (or $M_B < -19.5$) for $\alpha = -1.0$, and $L_{4,400\,\text{Å}} > 6 \times 10^{40}$ erg s^{-1} Å^{-1} (or $M_B < -22.0$) for $\alpha = -2.0$ (this range of α is compatible with the ionizing continuum inferred from the emission-line ratios[10]). Although these luminosities are likely to be substantially underestimated because f is probably much smaller than unity, they are comparable with the nuclear luminosities of Seyfert 1 galaxies, but are somewhat greater than the nuclear luminosities of Seyfert 2 galaxies[13,14]. Further, the aperture photometry[15] and the lack of dilution of the stellar absorption features near the nucleus in our long-slit spectra together suggest that the nuclear non-stellar luminosity of NGC5252 itself (inferred from our line of sight) is smaller than these estimates. Hence, our observations are consistent with the hypothesis that NGC5252 would look much brighter—possibly like a Seyfert 1 galaxy—to an observer within the cone.

NGC5252 has a relatively low total radio power, so it is also of interest to compare its properties with those of more powerful radio sources ($P_{6\text{cm}}^{\text{tot}} > 10^{22}$ W Hz^{-1} sr^{-1}). We note that the extent of the emission lines, the high ionization spectrum and the emission-line luminosity in NGC5252 are typical of the EELR around powerful radio galaxies and quasars (refs 16–18 and S. de Serego Alighieri, manuscript in preparation). It is more difficult to compare the opening angle θ, because few powerful radio galaxies have such well defined cones. The statistics of the alignment between the very extended emission-line regions and the radio-emission axes in powerful radio sources[19], however, are consistent with the value of θ we have derived here. Similar values of θ are also required by schemes

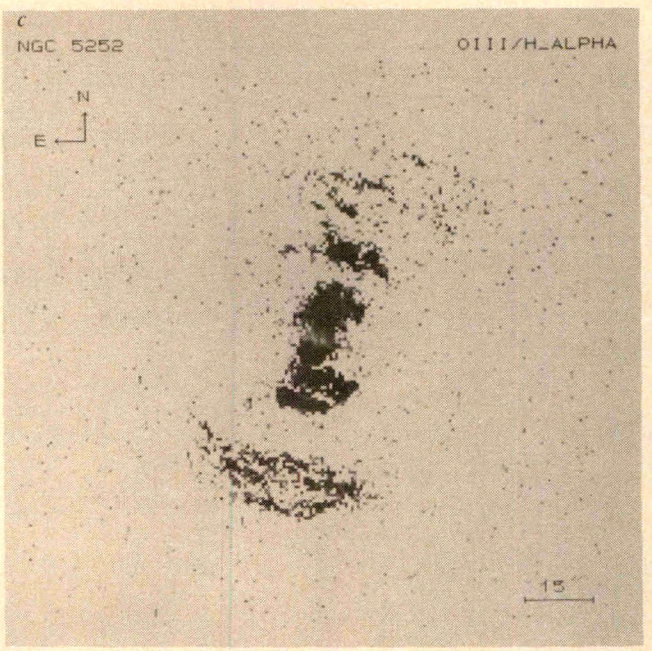


FIG. 1 Images of NGC5252. *a*, Continuum-subtracted [O III] image (exposure time 2 × 600 s). *b*, Line-free continuum image through filter centred on 5-210 Å (exposure time 2 × 600 s). *c*, Map of the ratio of the [O III] to the Hα line: darker shades represent larger [O III]/Hα. In all the images North is to the top and East to the left. Using an RCA type SID 503 CCD (charge-coupled device) detector the pixel scale was 0.675 arcsec, which compares with an estimated seeing of 1.2-arcsec full width at half maximum throughout the observations. The data were processed with the MIDAS software package[23]. Reduction consisted of registering the images using the centroids of stellar images on the frames and flux calibration using a standard star observed immediately after the object. The continuum images were scaled to the line + continuum images assuming a standard shape for the galaxy spectrum. The scaling factors were later checked with our spectral data and were estimated to be in error by <5%, thus confirming that the conditions were photometric at the time of the observations.

that attempt to unify radio galaxies with quasars[20]. Therefore, disk obscuration should be considered as a viable alternative to relativistic beaming as the radiation collimation mechanism in the powerful radio sources.

In general, our narrow-band images of NGC5252 support the idea that anisotropy/orientation effects play an important role in determining the appearances of active galaxies. □

Strike-slip faulting of ridged plains near Valles Marineris, Mars

Richard A. Schultz

Geodynamics Branch, Code 621, NASA Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

THE surface of Mars shows abundant evidence of extensional and contractional deformation in the form of normal faults, grabens and wrinkle ridges[1–3]. In contrast, strike-slip faults have been considered to be extremely rare or absent on Mars[4,5]. This view is based on the lack of significant lateral offset of pre-existing markers such as craters across suspected faults. Thus, Mars is believed to have evolved without plate tectonics or other large-scale lateral motions of the lithosphere[6]. However, careful study of Viking Orbiter images is revealing that strike-slip faults may be present on Mars[7]. Here I identify and document several well preserved examples of martian strike-slip faults and examine their relationships to wrinkle-ridges. The strike-slip faulting predates or overlaps periods of wrinkle-ridge growth south-east of Valles Marineris, and some wrinkle ridges may have nucleated and grown as a result of strike-slip displacements along the echelon fault arrays. Lateral displacements of several kilometres inferred along these arrays may be related to tectonism in Tharsis.

The inferred strike-slip faults deform moderately cratered plains of presumed volcanic origin south-east of Valles Marineris in Coprates[8] (Fig. 1). Wrinkle ridges of north–south strike also deform plains materials throughout the area (Fig. 2). The strike-slip faults are defined by a series of echelon linear structures that bound polygonal or rhombohedral plateaus located within their stepovers (Fig. 3). These arrays of echelon structures and plateaus are oriented obliquely (~60°) to the overall trend of the wrinkle ridges. The arrays of echelon structures and plateaus are morphologically distinct from typical wrinkle ridges on the Moon and Mars[9,10]. The plateaus do not seem to result from disruption and lateral offset of pre-existing wrinkle-ridge topography because the ridges do not match up across the echelon structures. Further, the location of plateaus within stepovers argues against simple offset because not all of the echelon arrays that have plateaus are associated with wrinkle ridges or other high topography outside the stepover (Fig. 3*a*). Thus, the presence of polygonal plateaus within the stepovers of echelon structures suggests that the plateaus formed as a result of mechanical interaction between the faults. Local high topography and basins are typically produced within stepovers along echelon fault arrays. For example, extensional basins can occur within stepovers along overlapping spreading centres[11,12] and extensional stepovers along strike-slip faults[13]; however, uplifts or basins are not generally associated with stepovers between dip-slip faults[14]. High topography can occur within contractional stepovers along strike-slip faults. Well-known examples include the East Bay Hills and Ocotillo Badlands uplifts along the San Andreas fault in California and horsts along the Hope strike-slip fault in New Zealand[15–17]. The rhombohedral shape of certain plateaus, such as the large composite one in Fig. 3*a*, is consistent with the geometry of rock fracture in a strike-slip stepover (see ref. 14). Hence, the linear echelon structures in Coprates are probably strike-slip faults and the plateaus correspond to uplifts within contractional stepovers. Previous workers[18–20,7] have interpreted echelon morphology within wrinkle ridges or other linear zones as evidence for strike-slip faulting. Here I document echelon geometry between wrinkle edges and note the scale independence of deformation associated with echelon geometries.

The echelon linear structures and plateaus on Mars are similar geometrically, and probably mechanically, to strike-slip faults and push-up ranges on the Earth (Fig. 4). The correlation between overlap and separation suggests that push-up length (overlap in Fig. 4) is related to propagation of faults in echelon arrays[21] rather than being directly proportional to fault offset (see ref. 13). The minimum horizontal shortening associated with martian push-up ranges can be estimated by assuming that the plateaus are fault-bounded rigid blocks. Horizontal shortening is given by $S = 2(h/\tan d)$ for a push-up range bounded by two reverse dip-slip faults, where h is the push-up relief and d is the fault dip (30° for thrust faults). Plateau relief obtained from shadow-length measurements ranges from 200 m (composite push-up in Fig. 3*a*) to 780 m (superimposed ridges in Fig. 3*b*), with uncertainties of ~10–50%. Cumulative horizontal shortening along the north-west- and north-east-trending fault arrays (Figs 3*a* and *b*) is ~1.4 and 2.0 km, respectively. This kinematic estimate probably underestimates shortening because it assumes rigid materials with no internal deformation in the stepover region and neglects deformation within wrinkle ridges located near fault terminations. This relationship suggests that

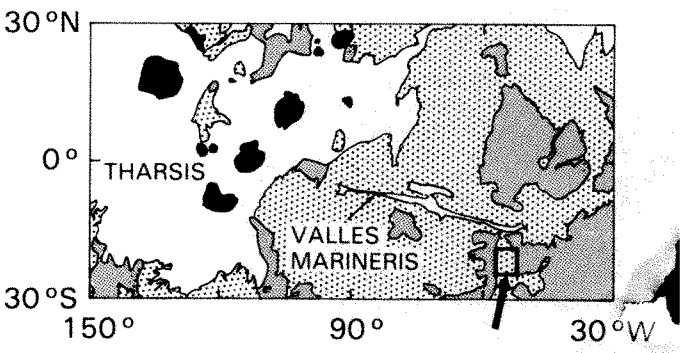

FIG. 1 Location map of western Mars indicating region of strike-slip faulting (inset marked by arrow). Dark shading, old (Noachian age) basement materials; light shading, intermediate age (Hesperian) plains materials; black, central volcanos; unpatterned, younger (Amazonian age) materials.

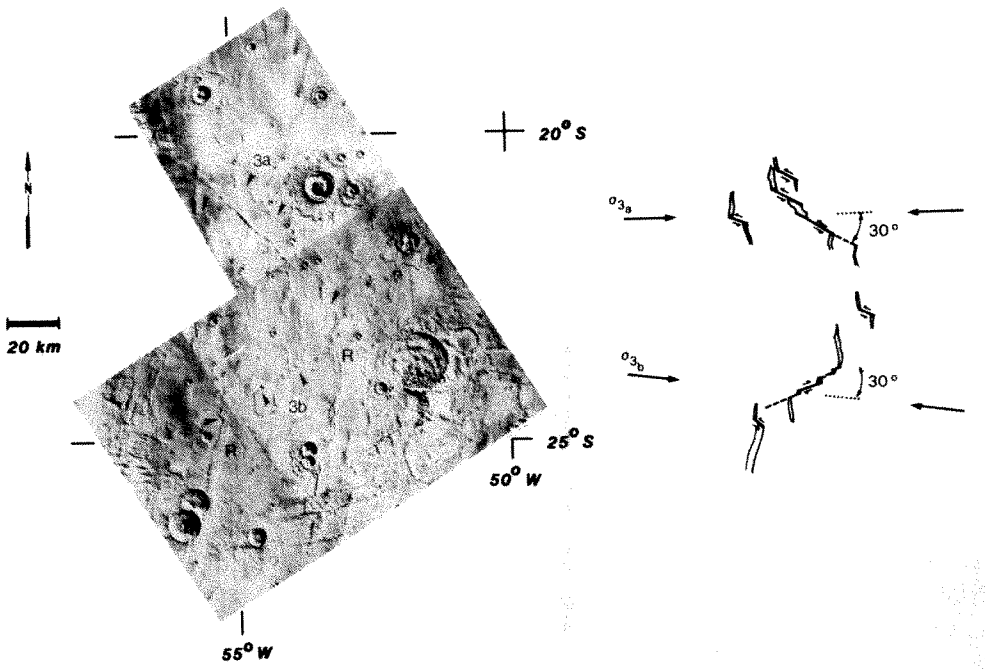

FIG. 2 On the left, a mosaic of medium resolution (220 m pixel^{-1}) Viking Orbiter images (610A27, 610A44, 610A46) showing north-trending wrinkle ridges (R) and oblique-trending strike-slip faults (arrows). 3*a* and 3*b* refer to enlargements in Fig. 3. Interpretation of relationships between echelon strike-slip faults and wrinkle ridges shown on the right. Orientations of maximum compressive principal stress inferred from left-lateral faults ($\sigma_3 a$), N90W; from right-lateral faults ($\sigma_3 b$), N80–85W.

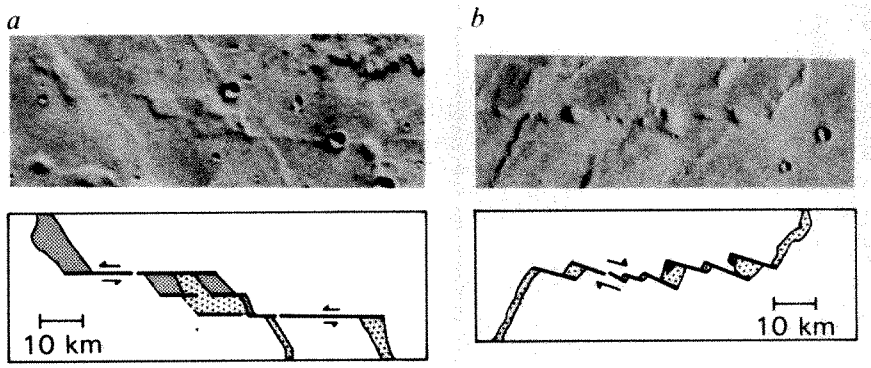

FIG. 3 Examples of martian echelon strike-slip faults. Plateaus and wrinkle ridges indicated by light shading; areas of high topography superimposed on other plateaus or ridges, dark shading. *a*, Right-stepping, left-lateral echelon faults. *b*, Left-stepping, right-lateral echelon faults.

the horizontal offset (shortening) along strike-slip faults in Coprates exceeds the vertical offset (push-up height) by at least a factor of two to three.

Determination of the sense of slip along echelon strike-slip faults is straightforward given the type of stepover and sense of step. For example, contractional stepovers occur for right steps along a left-lateral fault or left steps along a right-lateral fault. The north-west-trending strike-slip faults (Fig. 3*a*) step consistently to the right, implying left-lateral slip along the echelon array. The north-east-trending faults to the south (Fig. 3*b*) step consistently to the left, implying right-lateral slip along that array. Secondary extensional structures such as end-cracks, joints and normal faults or contractional structures such as stylolites, folds and reverse dip-slip faults can grow near strike-slip fault terminations as a result of fault slip[22,23], and the locations of these structures depend on the sense of slip. Consider a strike-slip fault in the map view located at the origin of a local *xy* coordinate system along the *x*-axis. For a right-lateral fault, large horizontal compressive stresses build up in the first and third quadrants, promoting nucleation and growth of folds and reverse dip-slip faults. Similarly, compressive stresses are increased in the second and fourth quadrants of left-lateral faults. The right-lateral fault arrays in Fig. 3*b* are associated with wrinkle ridges in the first and third quadrants, and left-lateral faults in Fig. 3*a* join wrinkle ridges in second and fourth quadrants. Wrinkle ridges are notably absent in the opposing, extensional quadrants of these faults. These relationships suggest that these wrinkle ridges may have nucleated in response to slip along the strike-slip faults and propagated away from the fault-termination regions. High-angle (but not orthogonal) intersections between wrinkle ridges and the strike-slip faults are consistent with this hypothesis. The lack of observed orthogonal fault–ridge intersections implies that the faults did not serve as passive transform faults. The location and orientation of wrinkle ridges near terminations of strike-slip faults provide independent evidence that wrinkle ridges represent contractional deformation such as folding or reverse dip-slip faulting. In some cases, small crenulations that extend away from some fault terminations are superimposed on larger ridges (Fig. 3*b*), perhaps implying multiple stages of contractional deformation and local uplift. Angular relations between the strike-slip faults and wrinkle ridges and the localized, discrete deformation represented by both sets of structures suggest that inhomogeneous strain gave rise to ridged-plains deformation, not translation and rotation of rigid fault-bounded blocks.

Geometric relationships (see, for example, ref. 22) between several strike-slip faults and wrinkle ridges suggest that strike-slip faulting predated growth of at least some wrinkle ridges. In a few cases, however, apparent superposition of fault-termination wrinkle ridges on much larger ridges implies the reverse sequence. No examples were found that would suggest strike-slip faulting that clearly postdated wrinkle-ridge formation. Thus, it seems that strike-slip faulting predated and overlapped the episodes of wrinkle-ridge growth. Strike-slip and wrinkle-ridge deformation in Coprates are early-to-middle Hesperian in age (~ 3–3.5×10^9 yr BP, ref. 24).

The remote stress state associated with the martian strike-slip faults is inferred from their orientations and sense of slip. Using

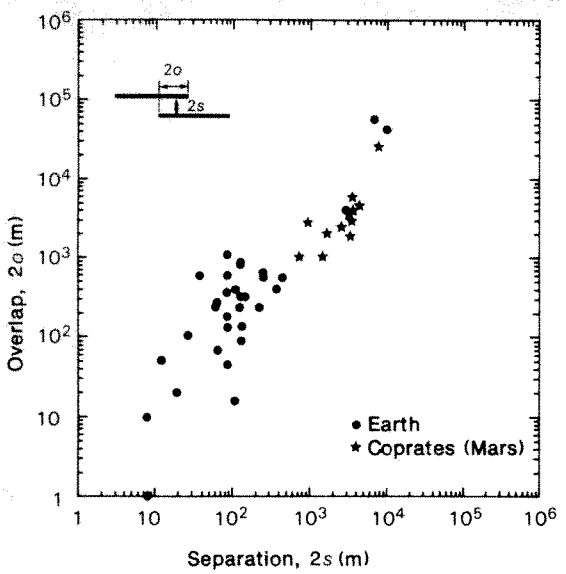

FIG. 4 Plot of overlap against separation of echelon strike-slip faults from Earth and Mars. Inset defines geometric parameters. Measurements of martian fault geometry from Fig. 2; terrestrial faults from ref. 21. Filled symbols, contractional stepovers. The geometry of echelon strike-slip faults on Mars is comparable to that of the terrestrial examples.

typical values of fault friction[25-27] and a Coulomb slip condition, the direction of maximum horizontal compressive principal stress σ_3 (tension positive) would be oriented 30° to the faults, or approximately east-west (Fig. 2). Orientations of maximum compressive stress associated with wrinkle-ridge formation obtained by assuming that σ_3 is orientated normal to the overall trend of the ridges[28-30] are very similar to those inferred from the strike-slip faults, and within ~30° of calculated Tharsis principal-stress trajectories[28-29]. It is likely that isostatic adjustments in the Tharsis region to the west[28] contributed to strike-slip faulting of Coprates ridged plains. The orientation of minimum compressive stress would, however, be vertical for wrinkle ridges but horizontal for strike-slip faults. Thus, strike-slip faults and wrinkle ridges can grow under the same remote stress state only if one set of structures changes the local stress state in such a way that the other structures can form. The geometry and relative timing of structures in Coprates indicate that some, but not all, wrinkle ridges nucleated and grew as a result of strike-slip faulting. Identification of the mechanisms for localizing strike-slip faulting in ridged plains and for relating along-strike variations of wrinkle-ridge morphology to ridge growth directions will help clarify the complex deformation history of martian ridged plains. □

Is ozone destroyed during the Antarctic winter in the presence of polar stratospheric clouds?

SINCE the discovery of the springtime Antarctic ozone depletion[1-2] a great deal of attention has been given to processes related to aerosol formation and heterogeneous chemistry at low temperatures. Polar stratospheric cloud (PSCs),[3] are frequent features of the southern winter atmosphere, and may provide a site for heterogeneous reactions that lead to ozone destruction[4,5]. Models have been proposed[6-8] for the formation of PSCs based on the condensation of HNO_3 (see ref. 9 for a review). An optical radar (lidar) has been operated at Amundsen Scott (South Pole), Antarctica, since the austral summer 1987–88. Observations made during the 1988 polar night show the presence of PSCs. Here we report ozonesonde measurements made quasi-simultaneously at the South Pole which indicate sharp minima of the ozone concentration in the vicinity of the PSCs. Although definitive information is unavailable for unambiguous interpretation of the results, the data may be viewed as evidence either for the role of dynamics in transporting air of different composition in conditions of substantial stability, or for processes leading to ozone destruction during the polar winter; the latter may include heterogeneous chemical reactions taking place in the absence of photolysis.

The lidar consists of a Nd YAG laser (532 nm) with a pulse repetition rate of 4 Hz, a Cassegrain receiving telescope of 0.5-m diameter and a two-channel photomultiplier detection system. A 1-MHz/12-bit digitizer inputs the data into a microcomputer that performs preliminary integration, storage and transmission of the data to the South Pole communications centre. The complete data set is stored on tape and retrieved when the station is no longer weather-bound. Meanwhile, samples of the data are transmitted to Rome by satellite.

As operated during the winter 1988, the instrument was capable of observing clouds and aerosols through the lower stratosphere. A more detailed description of the system and of the results will be given elsewhere. Lidar operation was not continuous during the first-year trial period; data were obtained, generally twice daily, during the periods 23-25 May, 21 June-12 July and 20 August-15 October. Drifts in the threshold of the sampling system and in the power emitted by the laser prevented data acquisition at altitudes ≥18 km.

Ozone and air-temperature profiles were obtained[10] using electrochemical-concentration-cell (ECC) sondes (telemetry systems on balloons) launched at the South Pole on a weekly basis during January-August, but more frequently in September. In winter, standard meteorological radiosondes are launched daily around 22:30 GMT by weather station personnel.

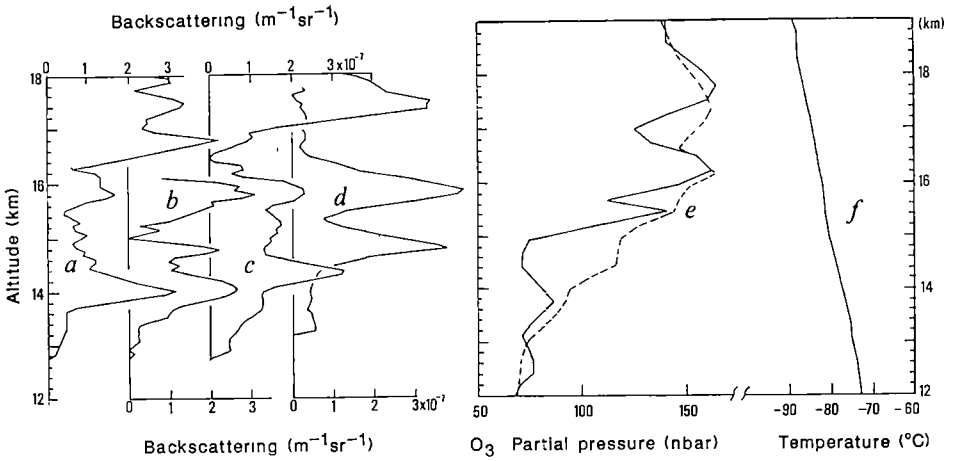

FIG. 1 (*a–d*), Aerosol backscattering profiles for 21–24 June derived from averaged half-hour lidar observations made around 22:30 GMT. *e* and *f*, ozone partial pressure and temperature profiles for 23 June, 02:55 GMT (solid curves). The dashed curve is the average ozone profile derived from five ECC ozonesonde measurements made in June

An important feature of the lidar data is the frequent appearance of PSCs when temperatures are ≤200 K. (PSCs were observed at all times during late May–early August.) From the lidar echoes it is possible to infer the volume backscattering cross-section of the aerosols by assuming that in certain height regions no aerosols are present. Backscattering values are of the order of 10^{-7} m^{-1} sr^{-1}, reaching a maximum of 6×10^{-7} m^{-1} sr^{-1} at 14 km on 25 June. There is a considerable day-to-day variability in the location and intensity of the stratifications.

A perusal of the 1988 ozone-partial-pressure profiles[11] shows the general yearly trend, with the ozone hole phenomenon becoming apparent in early September. We focus our attention on one of several minima which appear in mid winter in otherwise smooth profiles. The 'ozone hole' is consistently evident: There are sharp features on all ozone profiles taken between 11 June and 22 July, at altitudes between 14 and 18 km, where temperatures are <190 K. After 22 July the features disappear, to appear again around 1 September in smoother forms that can be seen as late as 19 October, which is the last day when temperatures are below the threshold for PSC formation.

A comparison of the aerosol and ozone profiles indicates that the ozone minima approximately coincide with the location of the PSC. The correspondence between aerosol layers and ozone minima is shown in Fig. 1 which depicts four half-hour-average aerosol profiles for 21–24 June (all taken around 22:30 GMT) and ozone and temperature profiles for 23 June, 02:55 GMT. (For reference, Fig. 1 also shows an average ozone profile derived from measurements made in June.) The ozone minima occur around 14.5, 15.6 and 16.9 km. Less than a day later (curve *c*), the intense stratifications around 14.4, 15.8 and 17.4 km were seen by lidar.

The columnar ozone depletion integrated through the height interval of the minima in the ozone profiles shown in Fig. 1 is of the order of 10^{21} molecule m^{-2}. Ozone minima and PSCs are present in all data sets obtained during June–July. Their spatial overlap seems to improve for lidar and ozone observations made closer in time. On 29 June, 22:43 GMT, aerosol stratifications occur at 15.8 km and 17.0 km and on the same day at 02.29 GMT a definite ozone minimum appears at 15.6 km. On 12 July at 22:55 GMT aerosol layers appear around 14.5 km and at 15–16 km, and on 13 July at 08:17 GMT ozone minima occur at 15.5 km and at 16.0 km.

The records indicate the disappearance of the ozone-reduction features during August; the lidar, however, was inoperative during July 13–August 19. When lidar operation resumed, PSCs could still be observed. In late August they maintained some of the sharp features evident in the first part of winter but during September such features tended to smooth out. This may be due to the onset of turbulent mixing as well as to the progressive hydration of the aerosol particles.

It is now generally accepted that the presence of PSCs in Antarctica induces a change in the equilibrium of atmospheric trace gas species that, because of photolysis during daylight, induces the catalytic cycle responsible for the ozone hole. During the polar night, however, no evidence has been found of possible chemical destruction of ozone

The simultaneous presence of the ozone and aerosol features may be ascribed to different mechanisms, as follows. (1) Air masses with low ozone contents and large amounts of condensable matter, possibly water, reach the South Pole stratosphere, structured in thin layers (1-km thick). No chemical interaction between constituents is implied: the ozone depletion is related to the origin of the air masses. (2) Air masses carrying PSCs pass in and out of darkness through sunlit regions where photochemical ozone destruction may occur. Thus, ozone may also be destroyed in Antarctica during winter and not only during springtime. (3) If the PSCs and HNO_3 condensates then ozone loss can occur in the formation of these clouds; NO_2 reacts with O_3 to yield N_2O_5 (this may occur in the absence of sunlight) and N_2O_5 is then converted to give HNO_3. Although this is a possible process on a small scale, it is unlikely to occur at the magnitude implied by the measurements. (4) Ozone is destroyed by reaction on PSCs.

Regarding (1) and (2) above, the geopotential surfaces indicate that a small wavenumber-1 prevailed in Antarctica during the month of June and that the centre of the polar vortex was displaced from the South Pole. There is no obvious evidence, however, that trajectories passing over the South Pole traversed regions outside the polar night. The maintenance of the sharp features observed in the ozone and PSC profiles for about one month requires either a continuous supply of thinly stratified air or, if it is the same air that goes around unmixed, a very slow vertical diffusion process (that is, modest amounts of turbulence, probably in the presence of substantial shear).

Although weak ozone–aerosol correlations have been noticed in the past at mid-latitudes in the aftermath of volcanic eruptions, sharply correlated features such as we report here have not, to our knowledge, been observed before. □

The role of cloud microphysics in high-cloud feedback effects on climate change

C. M. R. Platt

CSIRO, Division of Atmospheric Research, Station Street, Aspendale, Victoria 3195, Australia

THE effect of clouds on the radiation balance of the Earth (cloud forcing) is such that, on average, they cause the mean surface temperature to decrease. When the climate system is perturbed, the cloud forcing may change and this change will exert a feedback on the system. Climate models predict that clouds will have an overall positive feedback effect, that is, their presence will tend to enhance any surface-temperature changes, as in the greenhouse effect for example. The models preferentially increase the amounts of high clouds and their optical depths and decrease the amount of low clouds. Here I look at the temperature dependence of the infrared emittance of high clouds using data from a ground-based lidar/radiometer and *in situ* aircraft measurements of cloud properties. I conclude that the infrared emittances of high clouds are less sensitive to changes in temperature than predicted by climate models, chiefly because the microphysics of cirrus clouds modifies the relationship between cloud optical depth and cloud ice/liquid water path, in ways not accounted for in the models.

The annual-global-mean radiative temperature $\bar{T}_s$ is controlled by the balance of the incoming solar radiation that is absorbed by the planet and the terrestrial infrared radiation, the intensity of which is proportional to $\bar{T}_s^4$. The value of $\bar{T}_s$ is ~255 K or −18 °C, which would be the Earth's mean surface temperature ($\bar{T}_g$) without any atmosphere. $\bar{T}_g$ is actually much greater (~12 °C) because atmospheric trace gases, such as CO_2 and H_2O, are strong absorbers of infrared radiation over the whole terrestrial infrared emission spectrum, except for an 8–13 μm 'window' which allows surface radiation to escape to space. The absorbing gases re-emit to space high in the atmosphere to give an effective radiating temperature of T_s. At the same time downward emission to the Earth increases the surface value well above $\bar{T}_s$—the so-called greenhouse effect.

The value of $\bar{T}_g$ is further modified by clouds, which have a twofold effect. First, as they have a higher solar reflectance than most terrestrial surfaces, they reduce the radiation absorbed at the surface, thus reducing $\bar{T}_g$. Second, clouds absorb rather than scatter radiation at all infrared wavelengths, thus blocking emitted radiation from the surface in the atmospheric window, and re-emitting the radiation at cloud temperature, causing a reduction in planetary radiation to space and an increase in downwards radiation, thus increasing $\bar{T}_g$. The net magnitudes of the solar and infrared effects are such that low clouds cause a surface cooling, but high clouds result in surface warming[1,2]. Averaged over all cloud types and amounts, there is a surface cooling and $\bar{T}_g$ is reduced by ~18 °C from the cloudless value of ~30 °C[3–5]. Thus, on average, clouds seem to reduce the equilibrium warming that is due to trace gases by a significant amount. From these conclusions, however, we cannot predict what will happen when the climate is perturbed by an increase in CO_2, for example, because different cloud types may not change their optical properties equally.

Incorporation of cloud properties into global climate models (GCMs) is still rather crude so that prediction of the effects of clouds on climate change is only approximate. Some GCMs do now carry interactive-cloud schemes so that clouds can respond to climatic perturbations[6–9], but only cloud amount can vary. Recently, however, variable cloud liquid-water content, linked to cloud solar reflectance and infrared emittance, has been incorporated[10,11].

The above GCMs have consistently shown that an effective doubling of CO_2 increases the high-cloud amount but decreases the lower-cloud amount. Both these changes will cause a further increase in $\bar{T}_g$, that is, a positive feedback. Calculations[10] also show that the cloud liquid-water content increases everywhere. Although there is still a net planetary warming, $\bar{T}_g$ actually decreases[12]. Roeckner[10,11] performed a 20-year simulation using a GCM with coupled mixed-layer ocean and sea-ice models. The governing equations were solved at three vertical levels (850, 550 and 250 hPa) for a control model and for a model perturbed by 2% increase in the solar constant—roughly equivalent to a CO_2 doubling. They extracted changes in cloud quantities such as cloud liquid-water content (calculated from moisture continuity) and infrared emittances.

Here I compare the simulation[10,11] results at 250 hPa with two sets of results based on observations of cirrus clouds that have recently become available. These data were taken at a wide range of cirrus temperatures, so that I could calculate the temperature derivatives. One set of data comprises particle size distributions of cirrus clouds measured *in situ* from an aircraft at different atmospheric levels and temperatures and in a number of cirrus clouds[13]. The data show that the cloud infrared absorption coefficient, the ice/water content and the cloud-particle mode radius all increase with temperature[14,15]. The other set of data comprises remote observations on cirrus with a surface lidar and passive infrared radiometer[16]. These data include cloud infrared vertical-beam emittance, cloud depth and infrared absorption coefficient. The temperature variation of the absorption coefficient is similar to that found in the aircraft measurements. Some preliminary examinations[17] of feedback have been done using the combined data sets.

To compare model and observational results the above observed quantities must be related to the variables of the model. For example, the measured cloud vertical-beam emittance (ref. 16) is the radiance in a narrow cone of angles in a direction perpendicular to the cloud divided by the blackbody radiance at cloud temperature and in the same cone. The diffuse-flux emittance ε in ref. 10, however, refers to the total flux emitted at all angles from the cloud as measured by a horizontal detector, divided by the total cloud blackbody flux[18]. Now ε_a can be written $\varepsilon_a = 1 - e^{-\delta_a}$ where δ_a is the cloud absorption optical depth. It can be written as $\delta_a = K_a L = \sigma_a h$ where K_a is a mass absorption coefficient, L is the integrated vertical ice (or water) path, σ_a is the volume absorption coefficient, h is the cloud depth and I assume vertical homogenity in the cloud. L is related

TABLE 1 Cirrus mean cloud-water content and infrared absorption parameters deduced from lidar/radiometer and cloud microphysical measurements

† Data from lidar/radiometer and cloud microphysical measurements[13-16]

to ice/water content W by $L = Wh$ so that

$$K_a = \sigma_a / W \quad (1)$$

Now σ_a and W are proportional to the square and cube of the particle radius, respectively, and so[17] $\sigma_a = 2W/\pi r_e$ or $K_a = 2/\pi r_e$ where r_e is the cloud-particle mode radius. Thus, σ_a depends on both W and r_e.

As the simulation results give the changes of emittance it is instructive to see how changes in ε with T relate to the other quantities. As ε is a function of ε_a

$$\frac{d\varepsilon}{dT} = \frac{d\varepsilon}{d\varepsilon_a}\frac{d\varepsilon_a}{dT} \quad (2)$$

or

$$\frac{d\varepsilon}{dT} = \frac{d\varepsilon}{d\varepsilon_a}(1-\varepsilon_a)\left(K_a\frac{dL}{dT} + L\frac{dK_a}{dT}\right) \quad (3)$$

Various quantities derived from the observational data are shown in Table 1. Values of ε_a, h and σ_a were obtained from the lidar and radiometer studies[16] and values of K_a were obtained from the cloud-particle spectra[15]. Values of σ_a previously calculated[15] from cloud-particle spectra agreed well with the lidar/radiometer data[15]. Values of K_a from the cloud-particle spectra were extrapolated for temperatures < -55 °C. For consistency, values of W were calculated from equation (1), using the values of σ_a and K_a in Table 1. L was then calculated using the observed values of h.

Table 1 illustrates the large increases in W and L with temperature observed in high clouds. The mass absorption coefficient K_a decreases significantly, however, because the cloud-particle mode radius also increases, with the result that increases in σ_a (or δ_a) with temperature are much less than the increases in W (or L). (That is, the last term on the right-hand side of equation (3) is negative). These results imply that absorption (or extinction) must be parameterized in terms of r_e as well as W.

Changes in ε and L with temperature are compared with the model results[10] at 250 hPa in Table 2. The temperatures shown in column 2 were taken from ref. 19. As the temperature changes ΔT quoted in ref. 10, were appreciable, comparison values of $\Delta\varepsilon$ and ΔL were obtained from plots of ε and L as a function of T (using the data in Table 1) rather than from equation (3). The initial values of L are not quoted in ref. 10.

There is reasonable agreement between the values of ΔL, but values of $\Delta\varepsilon$ obtained from the simulation seem to be too high by factors of two or three. Stephens's parameterization[20], used in ref. 10, is considered quite adequate for lower-boundary-layer clouds and some deeper water clouds, but does not take account of the large changes in r_e, and therefore in K_a, in cirrus clouds. The values of K_a used in ref. 10 were apparently too high, implicitly neglecting the observed decrease in K_a with temperature. Somerville and Remer[21] introduced the inclusion of liquid water into GCMs but they also made δ proportional to L only. My results show the necessity of allowing for r_e.

Apparently Roeckner's calculated values of ΔT that are due to cirrus cloud are too large, because the increase in cirrus emittance is smaller than he predicted. As pointed out[10,12], the warming at cirrus altitudes will be counteracted by a net cooling at the surface because of a loss in solar radiation. According to Schlesinger[12], the overall radiative change is still positive, but my results indicate that this may not always be the case. □

Reconstruction of tree-line vegetation response to long-term climate change

Serge Payette, Louise Filion, Ann Delwaide & Christian Bégin

Centre d'Études Nordiques, Université Laval, Sainte-Foy, Québec, Canada, G1K 7P4

KNOWLEDGE of the vegetation response to climate change is necessary to assess and predict realistic ecosystem development in the anticipated, CO_2-induced warmer world, particularly at high latitudes where greater warming is expected[1-3]. Reconstruction of vegetation development over the past 1,000 years may be helpful in this respect, because this period was characterized by contrasting climatic conditions[4-9]. Here we report the reconstruction of wind-exposed, tree-line vegetation associated with long-term climate change in northern Canada, using tree-ring and growth-form analyses of spruce subfossils. Three major types of growth form within the exposed, but stable, lichen–spruce community successively predominated in response to climate forcing: high krummholz (dwarf spruce, <2-m high) with scarce small (>2-m high) trees (AD 1305–1435, cool period), trees (>2–3 m high) and high krummholz (AD 1435–1570, warm period) and low krummholz (≲50 cm) (little ice age to present: AD 1570 onwards, cold period and present climate, respectively). Whereas the expansion of a marginal lichen–spruce woodland climaxed during the late Middle Ages (AD 1435–1570), present development of a low-krummholz vegetation at these sites seems to be out of phase with the twentieth century warming. This suggests that ecosystem recovery to global warming is not straightforward, depending on the nature of vegetation structure present at the time climate change occurred. The implications of such ecosystem resilience for the detection and monitoring of the expected CO_2-induced warming is discussed, particularly for the climate-sensitive arctic and subarctic regions.

High-latitude tree-line sites are susceptible to changes in climate, where summer temperature[10] and winter conditions[11-13] represent the main restrictive factors for tree growth. Vegetation responses to climate change at such marginal sites involve com-

plex interactions between the two closely related processes of sexual reproduction and phenotypic plasticity in tree species. In black spruce (*Picea mariana* (Mill.) BSP), the dominant tree species in subarctic Canada[14], sexual reproduction occurs mostly in monopodial trees with normal stems, whereas krummholz are generally unable to produce a large number of cones and viable seeds[15]. The reaction of spruce to climate change may thus be different according to the type of dominant growth forms prevailing at the time the climate change occurred.

Old-growth tree-line vegetation that escaped fires during the past centuries in northern Québec is made of living and dead black-spruce stems of all ages[16,17]. Depending on the microsite conditions, dead stems remain undecomposed for several hundred years, 400–600 yr being the average apparent residence time for logs found at the soil surface. This provides the opportunity to reconstruct the recent stand history from living and dead material of wind-swept, old-growth coniferous sites in the Boniface River/Busk Lake area of northern Québec (57° 50′ N, 76° W). The area has a rolling, low-plateau topography made of small hills (the so-called upland sites: 150–200 m) protruding the lowlands (115–125 m). Present vegetation at all of the study sites is typically lowland and upland tundra—scattered or dense low krummholz, with dwarf birch (*Betula glandulosa* Michx.) and fruticose lichens. Small forest stands are located in snowy (80–150 cm of snow), protected sites. At upland sites, the stunted spruce (<30–50 cm high) have very narrow tree rings which are difficult to measure. The average snow depth rarely exceeds 30 cm, as suggested by mean height of woody vegetation. In contrast to the living vegetation in upland sites, leaning dead spruces are abundant at the soil surface and include several types of shrubby and arboreal growth forms. Tree subfossils in wind-swept lowland sites, however, are very infrequent. Spruce stumps were recovered from mires and, during a period of exceptionally low water level, from lakes.

Four sets of data were sampled. The first two sets included subfossil trees and the third set comprised subfossil high krummholz. Together these formed a mixed subfossil population that lay on the ground of exposed, low-krummholz communities situated on five small hilltops (Fig. 1). The fourth set, composed of large subfossil tree stumps recovered from lowland mires and lakes within a 50-km^2 area, was sampled for a comparative tree-ring and growth-form analysis with upland subfossils. Growth form, total height and winter damage (indicated by multiple-stem and branch leaders) of dead spruces were evaluated for all specimens found on the small hills presently under severely exposed snowless conditions (Fig. 1). A Henson micrometer (0.01-mm precision) was used for tree-ring measurements of finely sanded stem sections. Standard tree-ring techniques[18] were applied only to stem disks without reaction wood[19] (eccentric tree ring development in the direction of stems tilted towards the ground). Although missing or incomplete tree rings were common, cross-dating of spruce wood was facilitated by the available light-ring (tree rings without latewood cells or showing reduced latewood-cell development) chronology[20] supplemented by new records of light-ring years, especially between AD 1305–1560 (A.D., L.F. and S.P., unpublished data). Because an unknown proportion of outer rings was removed from dead stems by weathering and decomposition, reported dates of stem mortality may be in error by 10–20 yr. Four tree-ring chronologies based on spruce growth forms were deduced: upland-tree chronology from disks above the inferred snow-air interface (AST (above-snow tree), AD 1372–1799, including 34 radii from 21 samples), upland-tree chronology from disks below the inferred snow-air interface (BST (below-snow tree), AD 1350–1803, including 28 radii from 16 samples), upland-krummholz chronology from disks below the inferred snow-air interface (BSK (below-snow krummholz), AD 1305–1811, including 23 radii from 15 samples) and lowland-tree chronology (LT, AD 1425–1789, including 13 radii from 7 samples). In Fig. 2 we present curves of the mean width of tree rings of these spruce growth forms, which give direct evidence of past climate change.

Cross-dating of subfossil stem parts used in the tree chronologies indicate that normal trees developed at both upland and lowland sites between AD 1435 and 1570 (Fig. 2, AST and LT time series). Periods of faster growth recorded in the AST chronology around AD 1435–1450, 1495–1525 and 1550–1570 coincided with active upright-stem development above the critical snow-air interface, whereas only small stems developed around AD 1375, 1585 and 1740. Based on the frequency of stem development above the inferred snow-air interface, upland sites were occupied by lichen-spruce communities made up mostly of high krummholz with scarce small trees between AD 1305 and 1435. Marginal woodlands dominated by high krummholz and larger trees expanded between AD 1435 and 1570. According to the morphological features of subfossil spruces, the average snow-air interface was in the range 50–80 cm above the ground surface before AD 1570, after which it decreased steadily to its modern level of 30 cm. As stem development above the inferred snow-air interface also declined after AD 1570, clearly shown by the tree-ring patterns in all tree chronologies, stem dieback intensified particularly during the

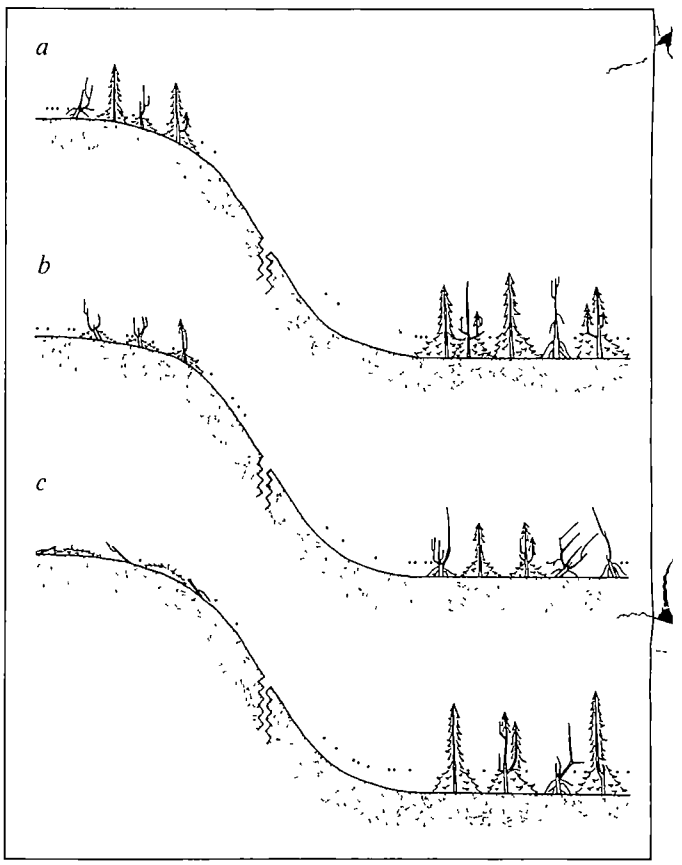

FIG 1 Vegetation reconstruction in exposed tree-line sites from *a*, late Middle Ages to *b*, little ice age and *c*, the present, in comparison with spruce development in snow-protected forest sites during the same period (ref. 16 and C.B., unpublished data). Presence or absence of vertical stem development above the snow cover (dotted line) constitute the best indication of present and past climatic conditions in cold subarctic environments. Sampling was stratified according to position above and below the inferred snow-air interface. Three data sets were used in the reconstruction. The first two sets associated with subfossil trees (in black) were composed of tree-stem sections or disks sampled respectively below and above the inferred snow-air interface shown in *c*, as determined by morphological traits such as abrupt changes in stem diameter and multiple stem leaders. The third set was made of subfossil krummholz (in black) sections all located below the inferred snow-air interface. Vegetation reconstruction was inferred from cross-dated subfossil spruces, which show distinct growth-form patterns (krummholz and tree) through time.

17th century (Fig. 2, AST and LT time series). From AD 1570–1580 onwards, a period corresponding to the onset and full development of the little ice age, the rate of stem dieback became considerably higher than production of new above-snow stems. Only snow-protected parts of tree and high krummholz survived at these sites until the 18th and 19th centuries, when new growth was in the form of small, horizontal spruce layers (Fig. 2, BST and BSK time series). Because sustained dieback proceeded continuously during this period, marginal lichen-spruce woodlands that developed during the AD 1435–1570 period progressively changed towards exposed, snowless, low-krummholz communities. Most of the creeping spruces which dominate present upland vegetation are survivors, through the process of layering, of 16th century spruces.

Tree-ring patterns of the four chronologies were closely associated with the temporal development of the spruce growth forms (Fig. 2). Highly significant correlations (0.01 level) were found between all time series (r ranging from 0.61 to 0.74, except between the BSK and LT chronologies where $r = 0.46$). The strongest associations are between the tree time series, which indicate quite similar growth conditions associated with the climate and growth habit. The lowest mean ring width and standard deviation of ring widths were from the BSK time series (0.18 ± 0.06 mm), which expressed the slow development of high krummholz with their foliage and growth meristems mostly concentrated less than 1 m above the ground. Faster growth and higher variability of ring width in the AST (0.21 ± 0.10 mm).

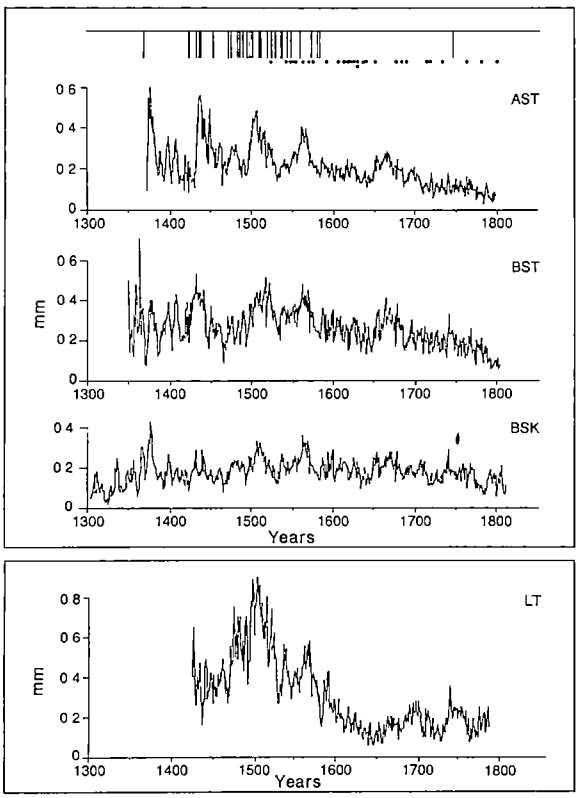

FIG. 2 Time series of ring widths from upland and lowland sites at the tree-line Upland-tree chronologies AST (disks sampled above the snow–air interface) and BST (disks sampled below the snow–air interface) Upland-krummholz chronology BSK (disks sampled below the snow–air interface) Lowland-tree chronology. LT, shown separately for comparison. Vertical bar. tree-ring date of onset of individual stem development above the snow–air interface Black dot maximum tree-ring date (apparent age +20 yr to account for the removal of outer rings by weathering and decomposition) of dieback of individual stems above the snow–air interface

BST (0.26 ± 0.09 mm) and LT (0.31 ± 0.19 mm) chronologies reflect the irregular periods of stem growth and dieback. Time-series mean ring widths calculated for the two major growth periods, as defined by tree development (before AD 1570) and tree dieback (after AD 1570), indicated relatively rapid growth before AD 1570 among tree chronologies (AST: 0.28 ± 0.10 mm before AD 1570, 0.16 ± 0.06 mm after AD 1570; BST: 0.31 ± 0.09 mm before AD 1570, 0.22 ± 0.07 mm after AD 1570; LT: 0.48 ± 0.16 mm before AD 1570, 0.18 ± 0.07 mm after AD 1570), whereas krummholz growth (BSK) remained fairly constant throughout (0.18 ± 0.07 mm and 0.18 ± 0.05 mm, respectively).

Such direct responses of upland lichen-spruce communities to climate change may help to predict future directions of vegetational change in the climate-sensitive Arctic and subarctic areas. A major feature to consider is the site sensitivity and the associated vegetation resilience to climate disturbance. Comparison of developmental sequences among strategic sites positioned along a wind-exposed toposequence indicate that, before the onset of the little ice age, both exposed (this study) and protected sites[16] (C.B., unpublished data, as shown in Fig. 1) responded positively to warming by favouring tree expansion and development of open woodlands, whereas severely exposed sites (composed of living and dead spruces showing the same prostrate, low-krummholz growth form) remained fairly stable from the late Middle Ages to the present (Fig. 1). Thus, differential vegetation responses to climate change only occurred during this century at the two former sites. Although protected lichen-spruce sites showed a shift from high krummholz to forest from the little ice age to 20th century, most of the exhausted creeping krummholz in exposed lichen-spruce sites have been unable to react positively to present warming. This situation may be explained by a marked difference in vegetation resilience between the lichen-spruce ecosystems. High krummholz located in protected sites were able to catch drifting snow and maintain the snow cover above the critical level for spruce survival during the little ice age. At exposed sites, the inability of creeping spruces to control the snow-drift environment was a key factor enhancing snowless conditions. Such conditions prevented seed production and seedling establishment in upland sites, whereas in protected sites large seed bearers were already present when recent warming started[16]. Whether the shift from snow-rich to snowless conditions in upland sites was associated with an exacerbated wind-disturbance regime caused by death of large pre-little-ice-age spruces unable to trap blowing snow, or to a major change in winter climate, or to both influences, is a question that deserves consideration.

Our data suggest that vegetation responses to global warming are not as straightforward as one may expect, as it is necessary to sort out the magnitude of climate change and the importance of autogenic control involved in ecosystem resilience. Vegetation resilience to environmental change, as reported here along a wind exposure gradient, constitutes an important ecosystem attribute. The amplitude and duration of recent warming were probably not large enough to compensate for the detrimental effects of the long-lasting cooling of the little ice age on exposed sites. Accordingly, recovery of the stand to its state before the little ice age would require a much milder winter climate in order to significantly increase winter survival of buds and needles, a necessary step to achieve stem development, cone production and spruce regeneration. Although recent climatic data indicate sustained global warming[21] during this century, no conclusive evidence of a positive vegetation response to such warming has yet been identified at these exposed tree-line sites. A reliable test for assessment of substantial global warming associated with rising atmospheric carbon dioxide at the arctic-subarctic transition, that is, warming that could overcome current wind and snow effects, would thus be from direct field evidence of vertical growth-form development leading to a type of ecosystem at least similar to that of the AD 1435–1570 period. □

Earthquake recurrence and risk assessment in circum-Pacific seismic gaps

Wayne Thatcher

US Geological Survey, Menlo Park, California 94025, USA

THE development of the concept of seismic gaps, regions of low earthquake activity where large events are expected, has been one of the notable achievements of seismology and plate tectonics. Its application to long-term earthquake hazard assessment continues to be an active field of seismological research. Here I have surveyed well documented case histories of repeated rupture of the same segment of circum-Pacific plate boundary and characterized their general features. I find that variability in fault slip and spatial extent of great earthquakes rupturing the same plate boundary segment is typical rather than exceptional but sequences of major events fill identified seismic gaps with remarkable order. Earthquakes are concentrated late in the seismic cycle and occur with increasing size and magnitude. Furthermore, earthquake rupture starts near zones of concentrated moment release, suggesting that high-slip regions control the timing of recurrent events. The absence of major earthquakes early in the seismic cycle indicates a more complex behaviour for lower-slip regions, which may explain the observed cycle-to-cycle diversity of gap-filling sequences.

The seismic gap concept originated from the work of Fedotov[1] and Mogi[2], who examined the relation between seismicity and the occurrence of great earthquakes on the margin of the northwest Pacific. They noted that over a time interval of about 30 years, the spatial distribution of background seismic activity defined a long linear belt interrupted by a number of conspicuous gaps. The seismicity belt was comprised of the aftershock zones of individual great earthquakes, which outlined adjoining regions but did not significantly overlap. In the areas of low activity, the seismic gaps, there had been no large or great earthquakes during the preceding decade or more. Historical records indicated that great events had occurred in the gaps during the late 19th or early 20th centuries, however, and several of the gaps did rupture in the years 1952–1963. Fedotov and Mogi recognized the forecasting implications of this observation and suggested that large events should be expected in the remaining gaps. Between 1968 and 1973 there were major earthquakes[3] in four of these gaps.

The discoveries of plate tectonics immediately supplied a simple rationale for these empirical inferences[4]. The long linear seismic belt defined the boundary between the Pacific and Eurasian lithospheric plates. The gaps represented unruptured segments in locked frictional contact where relative plate motion was building up elastic stress that would ultimately be relieved in great earthquakes. These conclusions quickly led to a recognition that the seismic-gap concept could be applied to make qualitative assessments of long-term seismic hazard on major plate boundaries throughout the world[3–6]. These applications have been remarkably successful: up to 1988, 13 identified circum-Pacific seismic gaps have subsequently ruptured in large or great earthquakes[7].

During the past ten years, research has increasingly been directed towards quantifying the timing of long-term earthquake predictions and integrating these estimates into a probabilistic framework[8–13]. At the same time, new work has highlighted several unresolved issues which limit the confidence that can be placed in the newer quantitative assessments. Gap-filling events have differed in size from those expected[14–17], some observations suggest very irregular recurrence[18,19] and many recurrence estimates critically depend on the assumed behaviour of plausible but idealized models[8–13,20,21]. These difficulties raise questions concerning the degree to which long-term hazard can be quantified and the applicability of simple conceptual models to earthquake recurrence. To clarify these issues and the origins of observed recurrence behaviour, I have examined observations of repeated rupture of specific segments of subduction zones in the circum-Pacific region. These are summarized for the two most recent cycles of earthquake strain release in Fig. 1, and further details of these and earlier events are contained in refs 8, 14–17, 22–26.

An important feature of Fig. 1 is the complete absence of repeated events with similar source characteristics. Commonly, a single long rupture is succeeded by several gap-filling events in the next episode of earthquake strain release (Valparaiso, Colombia, Peru, Michoacan). Sometimes this involves encroachment of rupture into or from an adjacent segment (Southern Chile, Concepcion). In several instances, not all of the plate boundary segment defined by preceding events has ruptured (Nankai and Kanto) and for several recent shocks (1979 Yakataga, 1986 Aleutians) only a small fraction of the seismic gap has yet been filled. Although the 1918 and 1963 Kurile earthquakes are generally similar, their mainshock epicentres are separated by 200 km.

A second notable feature of Fig. 1 is the timing, source size and magnitude pattern of gap-filling episodes that involve several events. These characteristics are summarized in Fig. 2, which shows that each event in the sequence invariably occurs in the last half of the seismic cycle, the majority being concentrated in the last 20% of the cycle. Furthermore, events show a strong tendency to increase in magnitude and rupture length toward the end of the cycle. The cycle duration in each region is defined by the largest events in the two most recent strain-release episodes. In four of the regions, times between the preceding great earthquakes are comparable to cycle durations defined in this way[8,17,22]. For Peru the average interval is 194 yr for the past 2 cycles, for Concepcion 98 yr (4 cycles), for Valparaiso 85 yr (4 cycles), and for Nankai 112 yr (4 cycles). In the three other regions (Colombia, Kanto, Michoacan), the seismic history is too poorly known to independently confirm my choice of cycle duration[15,23,26].

In many quantitative assessments of long-term risk the size of gap-filling events is not directly addressed and it is tacitly assumed that the expected earthquake will have the same features as the most recent preceding event. Previous studies have shown, however, that in several regions gaps have only been partially filled[27], events were smaller than expected[14] or several shocks occurred when only a single event was anticipated[15–17]. The larger dataset shown in Fig. 1 shows that it has

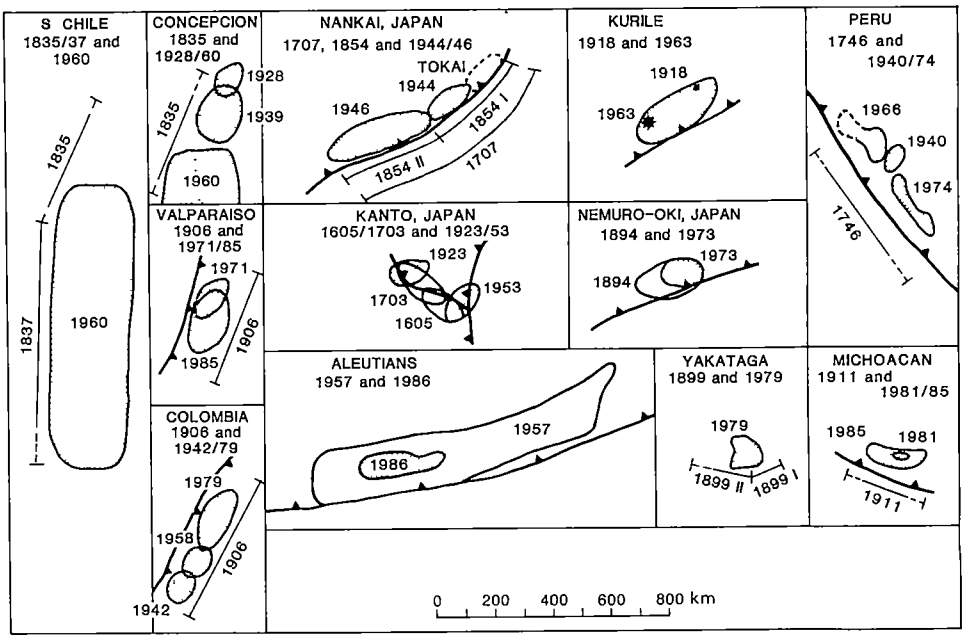

FIG. 1 Map views of extent of gap-filling earthquake ruptures on 12 segments of circum-Pacific plate boundary North is towards the top of each frame. The trench axis, the surface trace of the convergent-plate boundary, is shown by a thick solid line with teeth on the overriding lithospheric plate Extent of rupture for each event is given by aftershock zone, tsunami source area or distribution of seismic intensities In each region the extent of the most recent event or sequence of events is indicated by stippling. For some of the earlier events the area of rupture is not well determined and source extent is indicated by straight line segments, dashed where uncertain

been difficult to forecast the character of gap-filling events because cycle-to-cycle diversity is seen to be typical rather than exceptional. At the same time, the concentration of sequences of events late in the seismic cycle can be of practical value in anticipating future activity, as the partial rupture of an identified gap may signal the imminence of more (and larger) events. Conversely, if major portions of identified seismic gaps have ruptured in one or more great events, the results summarized in Fig. 2 suggest that smaller shocks will not fill in the remainder of the gap until late in the subsequent cycle of seismic-strain release (for example, the Tokai segment in Nankai region, Fig. 1).

Historical documents or geological methods are increasingly being applied to determine the times between previous earthquakes[28,29], providing a firmer perspective on the significance and level of hazard implied by the present repose intervals in unruptured gaps. Whereas probabilistic calculations usually assume that inter-event times are tightly clustered about a mean recurrence interval and some observations support this assumption[30], geological investigations on the San Andreas fault in southern California have recently uncovered evidence of very irregular recurrence[18,19]. The temporal pattern of gap-filling earthquake sequences shown in Fig. 2 has several similarities with the southern California observations. There, inter-event times range from as short as 45 yr to more than 300 yr, but the ten dated events occur in clusters of two or three shocks that span intervals of $\leqslant$100 yr and are separated from adjacent clusters by 300–400 yr. Except for the historical earthquake of 1857, the magnitude and source extent of the California events is unknown. Furthermore, whereas the circum-Pacific sequences usually occur in spatially distinct rupture zones that do not significantly overlap, the California chronology is determined at a single site. Nonetheless, the temporal concentration of events is strikingly similar, suggesting an underlying order in the recurrence of the San Andreas events that mimics the circum-Pacific sequences and implies a common mechanism.

When detailed earthquake chronologies are unavailable but the long-term fault slip or relative plate-motion rate is known, fault slippage in the most recent great earthquake has been used to estimate the time required to reaccumulate that slippage and generate the next great event (elastic-rebound model[31] or time-predictable[20] model). Frequently the detailed slip distribution in individual events is unknown and average or local slip estimates are used in recurrence calculations[8–13,20,21]. Although the general validity of the elastic-rebound model is widely acknowledged and some data support the expectations of the time-predictable model[20,21], the detailed precision of such occurrence-time predictions is uncertain.

Furthermore, whenever earthquake slip distributions have been well determined they invariably show considerable spatial heterogeneity, as Fig. 3 illustrates. Although it is difficult to forecast the character of gap-filling events because cycle-to-cycle diversity is seen to be typical rather than exceptional. At the same time, the concentration of sequences of events late in the seismic cycle can be of practical value in anticipating future activity, as the partial rupture of an identified gap may signal the imminence of more (and larger) events. Conversely, if major portions of identified seismic gaps have ruptured in one or more great events, the results summarized in Fig. 2 suggest that smaller shocks will not fill in the remainder of the gap until late in the subsequent cycle of seismic-strain release (for example, the Tokai segment in Nankai region, Fig. 1).

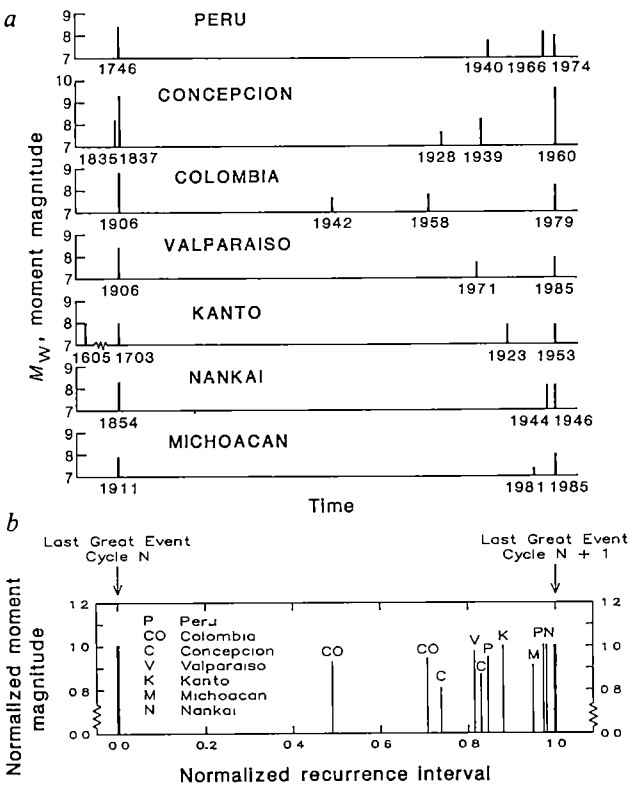

FIG 2 Magnitude as a function of time for earthquakes from the seven regions in Fig. 1 where the most recent episode of seismic strain release has involved more than one great gap-filling event. The duration of the seismic cycle is defined by the time interval between the last event in each strain-release episode *a*, Time–magnitude plots for each region, with duration of cycle normalized to the same measured length on the time axis of each plot. *b*, Data from *a* plotted on a single graph, with earthquake magnitude normalized by the last event of the most recent sequence in each region.

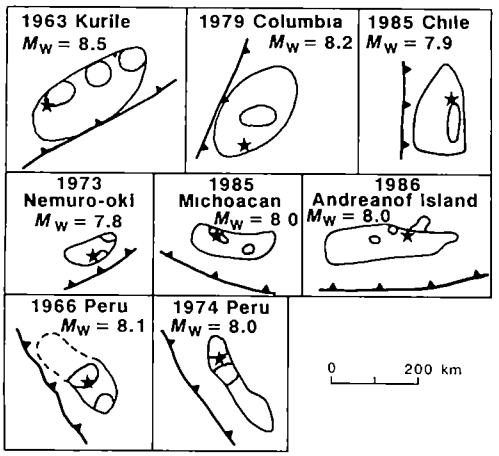

FIG 3 Spatial distribution of seismic moment release for eight of the most recent great earthquakes shown in Fig. 1[16,17,32–35] Extent of rupture in each event is delineated by aftershock zone. Regions of concentrated moment release are indicated by stippling Mainshock epicentre (the point of rupture initiation) is located by a star North is towards the top of each figure and trench axis is given by heavy line with teeth on overthrust lithospheric plate.

estimate slip distributions directly by seismic methods, the spatial pattern of seismic moment release (the product of slip, fault area and elastic shear modulus) is an informative measure of slip that is being determined for an increasing number of large events. Moment-release distributions for eight of the recent great earthquakes considered earlier (Fig. 1) are plotted schematically in Fig. 3. These results demonstrate that seismic slip is typically nonuniform but also show an association between mainshock epicentre and regions of concentrated moment release. For all but one of the eight events (1979 Columbia) the point of rupture initiation lies either within or immediately adjacent to the high moment-release regions, which themselves comprise only a small fraction of the entire rupture plane. A larger data set of 23 events (W.T., manuscript in preparation) shows the same general features. This association suggests that earthquake recurrence is more likely to be controlled by the maximum rather than the average coseismic slip, leading to consistent underestimates of inter-event times if average values are used.

The observations reported here suggest a relation between earthquake slip distribution and recurrence behaviour but also demonstrate complexities that are not easily explained by simple models. The close proximity of the mainshock nucleation point to zones of concentrated moment release suggests that the high-slip regions determine the event times. The time and magnitude patterns of event sequences shown in Fig. 2 can be rationalized if the high-slip regions rupture according to the time-predictable model, with failure occurring at stress thresholds determined by slip maxima in the preceding cycle of strain release. To the degree that cycle duration is uniform these high-slip zones may persist from event to event and sustain the same amount of slippage in each cycle of seismic strain release.

The behaviour of regions with less slip is more problematic. Because slip rate is essentially constant along the strike of major plate-boundary rupture zones, the spatial heterogeneity of earthquake slip generates regions of major slip deficiency with the occurrence of every great event. If these slip-deficient regions behaved time predictably, recurrent events would be expected as soon as plate motion reaccumulated slip to the level of that released in the preceding great earthquake. The considerable nonuniformity of earthquake slip indicates that such events should occur relatively early in the seismic cycle, and the concentration of event sequences in the latter 20% of the seismic cycle (Fig. 2) is a strong argument against simple time-predictable behaviour in the slip-deficient regions. □

PRYMNESIOPHYTE algae, which include the coccolithophorid species *Emiliania huxleyi*[1], are the recognized biological source of a series of long-chain (C_{37}, C_{38}, C_{39}), unsaturated methyl and ethyl ketones[2] widely observed in marine sediments[3]. Studies of *E. huxleyi* in culture have demonstrated that these biomarkers are attractive geochemical tools for palaeoceanographic study. Notably, unsaturation patterns within the alkenone series change regularly with growth temperature[3–5] and the total alkenone abundance in the living plant cell is relatively constant, accounting for 5–10% of the total cellular organic carbon[5]. If these compounds are relatively well-preserved in sediments, profiles of alkenone unsaturation patterns and total alkenone concentration with depth in dated deep-sea cores[6–8] provide a temporal record of sea surface temperatures and the productivity of an important group of marine phytoplankton[3–5]. Here we analyse the long-chain alkenone composition of sediment samples from above and below an oxidation front in an ungraded turbidite layer[9] deposited 140 ± 12 kyr BP in the Madeira Abyssal Plain[10], to evaluate the post-depositional stability of these biomarkers under contrasting redox conditions. The results demonstrate that >85% of the total amount

of these compounds is degraded over ~8 kyr as a consequence of diffusion-controlled oxidation[10]. Remarkably, such extensive degradative loss has little effect on the unsaturation pattern of the residual biomarker series. Thus, we find that long-chain alkenones provide reliable indicators of sea surface temperature in the ocean. The total abundance of these biomarkers in sediments, however, is controlled not only by prymnesiophyte productivity, but also by their degree of exposure to oxidative degradation in the sedimentary process.

Sediment cores from the Madeira Abyssal Plain (MAP), located in the north-east Atlantic Ocean, are characterized by a periodic sequence of thick (1–4 m) distal turbidites interbedded by thin (3–15 cm) pelagites[10–12]. The main source of these organic-rich turbidite materials is the continental margin off north-west Africa located ~700 km to the south-east. Nineteen major turbidite layers of late Quaternary age have been identified in various cores from MAP and correlated stratigraphically over distances of 200 km in this deep-sea basin, demonstrating the large geographic scale of these sediment transport events[11,13]. In general, the major turbidite layers observed in piston cores from MAP are ungraded silty clays[14] consisting of 40–70% biogenic calcite (primarily coccoliths) with the remainder composed predominantly of quartz and clay minerals. Some of the turbidite layers contain a relatively high total-organic-carbon (TOC) content (~1%) compared with the interbedded pelagic intervals (~0.2%). The surface portion (15–45 cm) of these turbidites is often distinguished from the deeper portion by a colour transition and by a significant reduction in TOC (~80%) and calcium carbonate (~10%) content. These observations imply that the upper portion of these turbidites has undergone post-depositional oxidation resulting from the diffusion of oxygen into the surface of the deposit during intervals of slow pelagic sedimentation[10,15]. The time required for the full evolution of these oxidation imprints on the geochemistry of these sediment records ranges from 2 to 15 kyr depending on the turbidite interval considered[10].

The two sampling sites from MAP examined in this study (86P5: 32°2.50′N, 24°12.50′W; 86P25: 30°44.23′N, 25°22.45′W) are separated spatially by >100 km. One sample from the oxidized layer and two samples from the unoxidized layer of the f-turbidite[10,11] identified in each of these cores were taken for analysis of their bulk inorganic and organic carbon content and their long-chain alkenone composition and content. The total volume of sediment represented by the f-turbidite at MAP is estimated[13] to be ~126 km^3. The age of these sediments is estimated at 140 ± 12 kyr, based on biostratigraphic and oxygen isotope age determinations of the thin pelagic strata located above and below this turbidite interval[10].

For the two sample sets taken from the f-turbidite[10,11], similar geochemical trends are noted at both bulk and molecular levels (Table 1). The concentrations (per g dry sediment) of TOC, calcium carbonate and total (C_{37}, C_{38}, C_{39}) alkenones are highest and nearly constant in the lower, unoxidized portion of the turbidite. Quite notably, the concentration for these three geochemical properties measured in the unoxidized intervals of the f-turbidite differs only slightly between these two widely separated sampling locations (86P5 and 86P25). These observations support previous evidence that MAP turbidites are distal and ungraded[11,14]. By contrast, a pronounced difference is evident when the chemical composition of the oxidized and unoxidized intervals of this turbidite are compared. For both cores, the TOC, calcium carbonate and total alkenone content of the oxidized samples are lower than the corresponding unoxidized samples by consistent factors of 83%, 6% and ~88%, respectively. This observation argues that the diffusion-controlled oxidation process acted uniformly on the f-turbidite deposited throughout this basin.

A compositionally uniform series of long-chain alkenones is widely observed in marine sediments ranging in age from recent to Tertiary[3]. The predominance of these biomarkers of prymnesiophyte algae[2] in the total-solvent-extractable-lipid fraction of sediments[3,16] argues that they are relatively more stable than most other lipids biosynthesized by marine plankton. Based on a close agreement between long-chain alkenone fluxes measured in sediment traps deployed at shallow depths for short periods of time and in underlying bottom sediments, Volkman *et al.*[17] suggested that these biomarkers are transported conservatively from surface waters to the ocean bottom in the Peru Upwelling

TABLE 1 Geochemical data obtained from analyses of oxidized and unoxidized sediment intervals from the f-turbidite in two cores (86P5 and 86P25) from Madeira Abyssal Plain

	Core 86P5			Core 86P25

Piston cores (86P5· 32° 02.50′ N, 24° 12 50′ W, 86P25· 30° 44.23′ N, 25° 22.45′ W) were collected from 5,400-m water depth by the Dutch Geological Survey (RGD) in 1986 aboard RV *TYRO*

* Total organic and inorganic carbon determinations were made by LECO carbon analyser using the wet oxidation technique described in ref. 23

† Total long-chain (C_{37}, C_{38}, C_{39}) alkenones were extracted from wet sediment by sohxlet using an azeotropic mixture of toluene in methanol and isolated from the total extract by column chromatography on silica gel. The column chromatographic fraction containing these compounds was analysed by gas chromatography using a 30 m × 0.25 mm inner diameter DB-5 fused-silica column (J&W Scientific), splitless injection, temperature programming (75–130°C at 10 °C min^{-1}, 130–300 °C at 5 °C min), hydrogen as a carrier gas (0 703 kg cm^{-2}) head pressure) and flame ionization detection. Individual compounds were quantified by an internal standard method using hexamethylbenzene as the internal standard. Further details of these methods are given in ref. 8. The unsaturation index $U^{K'}_{37}$ {$=C_{37:2}/(C_{37:2}+C_{37:3})$} is defined by the concentration ratio of the di-unsaturated C_{37} alkenone to the sum of the di- and tri-unsaturated C_{37} alkenone. This index is related to the growth temperature T of the phytoplankton source by the equation· $U^{K'}_{37} = 0.034 \times T + 0.039$. The parameters K37/K38 and EE/K37 are defined by the concentration ratio of total C_{37}·C_{38} alkenones and of di-unsaturated C_{36} ethyl alkenoate (EE) to total C_{37} alkenones, respectively, measured in each mixture. Further description of these parameters is given in ref. 5.

Zone In an open ocean environment, Prahl and Muehlhausen[18] compared the relative abundance of total alkenones to TOC measured in a sediment trap deployed at 3,900 m for >1 yr and in underlying surface sediments (4,400 m). Their results showed that these compounds were 2–3 times more reactive than TOC. Although the alkenones are selectively preserved relative to most other planktonic lipids, the latter observation implies that these biomarkers of prymnesiophyte algae are not a conserved property of sedimentary particles, at least in deep-water open-ocean environments.

Comparison of the total alkenone concentrations (per g C) measured in the oxidized and unoxidized portions of the f-turbidite (Table 1) yields an observation that agrees with the findings of the open-ocean sediment trap experiment. Total alkenones are not enriched relative to TOC in the oxidized portion of the turbidite as would be expected if these compounds were completely insensitive to biodegradation. Rather, these compounds are depleted to a somewhat greater extent than TOC (88% compared with 83%) by the diffusion-controlled oxidation process[10] that acted on the surface layers of the f-turbidite.

Similar to TOC[19], only a small fraction of the total quantity of long-chain alkenones biosynthesized in surface waters seems to survive transport through the water column and become preserved as a stable component of the sediment record. Emerson's model[20] for marine sediments suggests that the TOC burial flux in the deep sea depends on surface supply (productivity) as well as bottom-water oxygen content. Decreased availability of oxygen (and perhaps other oxidants such as nitrate) in pore waters should enhance the preservation efficiency of TOC in sediments. The magnitude of a change in TOC content noted down the core can, therefore, differ from that attributable to an absolute change in primary productivity if the bottom-water oxygen varies with time. The similar reactivity of the alkenones relative to TOC under contrasting redox conditions (Table 1) suggests that the stratigraphic record for the abundance of these biomarkers in sediments may also contain a significant, time-dependent preservational overprint.

Most palaeoceanographic studies are conducted with sediment cores from open-ocean environments. In these settings, the depth of zero oxygen in sediments is typically subsurface regardless of the magnitude of the surface-water productivity. Nonetheless, the depth of this boundary is not static but moves up or down in the underlying sediments in response to an increase or decrease in the supply of metabolizable organic carbon from above[21]. Hence, a change in productivity changes the thickness of the oxic layer in the sediment deposit and, therefore, the post-depositional exposure time of TOC and the alkenone biomarkers to oxygen. The results of this study do not address the sensitivity of these compounds to degradation under different oxygen exposures. Without a calibration of the behaviour of these biomarkers under different periods of oxygen exposure, stratigraphic records for alkenone concentration[6–8] can provide at best only a semi-quantitative sense of how the prymnesiophyte productivity in overlying surface waters has varied at a given ocean location over time.

In culture, *E. huxleyi* exhibits unsaturation patterns within the alkenone series that change regularly with growth temperature[3,5]. A plot of the index $U^{k'}_{37}$ (defined in Table 1) quantifies the degree of unsaturation in a given series as a function of growth temperature[3] T follows a remarkably linear trend ($r^2 = 0.994$) defined by the equation $U^{k'}_{37} = 0.034 \times T + 0.039$ (ref. 5). A test of this equation in the field has shown that it reliably predicts the unsaturation patterns measured in phytoplankton collected from ocean waters of known temperature[4]. Based on these findings and an assumption that values of the unsaturation index are not significantly altered in the sedimentary process, it has been proposed that stratigraphic profiles of $U^{k'}_{37}$ values down the core provide a temporal record of how sea surface temperature (SST) has changed in overlying waters on a relative[3] and perhaps an absolute[4] basis. Long-chain alkenones in the f-turbidite from MAP provide strong evidence to validate the assumption that values of $U^{k'}_{37}$ are not significantly altered in the sedimentary process, thus supporting the proposed applications[3,4]. Despite a major loss (~88%) in total alkenone content as a consequence of oxidative degradation, measured values of $U^{k'}_{37}$ in the oxidized and unoxidized intervals of the f-turbidite from cores 86P5 and 86P25 are practically identical (Table 1).

In calibrating the response of $U^{k'}_{37}$ values to growth temperature, Prahl *et al.*[5] monitored two additional compositional properties of the long-chain lipid series biosynthesized by *E. huxleyi*. These properties were the carbon chain length (K37/K38) in the C_{37}, C_{38} and C_{39} alkenone series and the distribution of di-unsaturated C_{36} fatty acid ethyl esters (alkenoates) to alkenones (EE/K37). K37/K38 and EE/K37 both vary non-linearly with growth temperature (Fig. 1*a* and *b*, open symbols). Values of $U^{k'}_{37}$, K37/K38 and EE/K37 were measured in MAP samples (Table 1) and in a variety of other sediment samples ranging in age from recent to late Pleistocene (≤26 kyr) and collected beneath warm tropical (MANOP Site C) to cold temperate (Multitracers and Washington coastal) waters. Values of K37/K38 and EE/K37 for these sediment samples (Fig. 1*a* and *b*, respectively, solid symbols) plotted against growth temperatures predicted from $U^{k'}_{37}$ values both show a trend paralleling the temperature calibration established for the laboratory culture. However, the sediment data are significantly offset from the laboratory calibration curves. Prahl

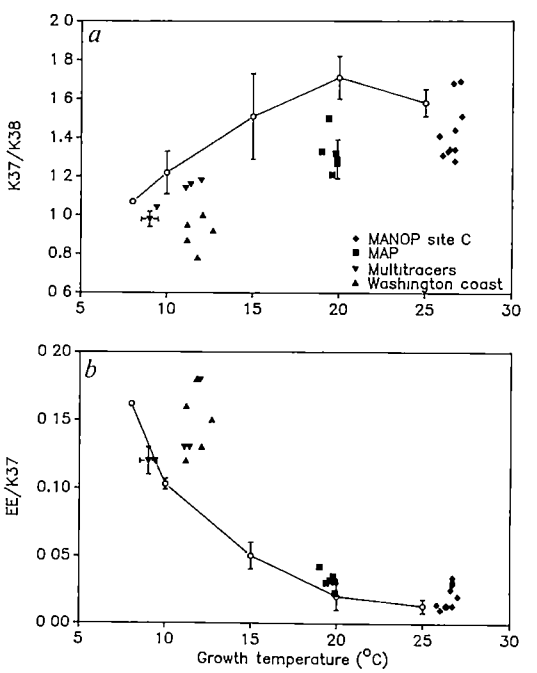

FIG. 1 Plots of *a*, the carbon-chain-length distribution (K37/K38) of the long-chain alkenone series and *b*, the di-unsaturated C_{36} fatty acid ethyl ester (alkenoate) to alkenone composition (EE/K37) measured in laboratory cultures of *E. huxleyi* grown at various water temperatures (open symbols, data from ref 5). Compositional data for the long-chain alkenone/alkenoate series measured in sediments from the continental shelf and slope off Washington state (Washington coast 46° to 47° N, 124° 26′ to 125° 5′ W; 73–2,235 m water depth), in sediments along an east–west transect (~42° N) extending from 126° to 132° W off northern California (Multitracers 2,500–3,000 m water depth), in sediments from the northern equatorial Pacific *T* (MANOP site C. 1° N, 140° W, 4,400-m water depth) and in sediments from the f-turbidite of the Madeira Abyssal Plain (MAP) are also plotted (solid symbols). Values of K37/K38 and EE/K37 measured in sediments from these different marine environments are plotted at growth temperatures predicted from values of the unsaturation index $U^{k'}_{37}$ measured in each mixture using the following calibration equation $U^{k'}_{37} = 0.034 \times T + 0.039$ (ref 5).

et al.[5] noted this offset between laboratory and field data before the analyses of sediment samples from MAP and the east–west transect off northern California (Fig. 1). The offset could reflect a simple physiological difference between the laboratory strain of *E. huxleyi* used to calibrate these compositional properties and the average prymnesiophyte species contributing long-chain alkenones and alkenoates to marine sediments. Alternatively, it could reflect selective degradation of the tri-unsaturated compounds in the alkenone series. Here we show that $U^{k'}_{37}$ values are virtually unchanged despite major oxidative degradation of the total alkenone signal in the f-turbidite (Table 1). Thus, the second explanation for the observed offset (Fig. 1*a* and *b*) is excluded. Furthermore, because the values for K37/K38 and EE/K37 in MAP sediments from the f-turbidite show little difference between oxidized and unoxidized intervals (Table 1), the discrepancy between the laboratory calibration curves and field measurements would now seem attributable to differences in the field and laboratory phytoplankton specimens.

The insensitivity of the unsaturation index to change despite extensive oxidative degradation of the overall alkenone signal in the surface of the f-turbidite is an ideal feature if values of $U^{k'}_{37}$ are to be useful palaeotemperature indicators. Further understanding of the ecology of prymnesiophyte species contributing to the alkenone record in marine sediments is needed, however, to aid an accurate palaeoceanographic interpretation of stratigraphic records of $U^{k'}_{37}$ with depth in deep-sea sediment cores. Because the source of these biomarkers is limited to particular photosynthetic algae[2], production of these compounds in the ocean is confined to the euphotic zone. Nonetheless, this zone is not necessarily isothermal and may include the top portion of the thermocline. *E. huxleyi* contains the antenna pigment, 19′-hexanoyloxyfucoxanthin, which allows it to photosynthesize at wavelengths between 500–550 nm (ref. 22). Thus, these algae are not restricted to the surface layers of the euphotic zone, but may be adapted to deeper portions of this layer where light intensities are lower, light quality is shifted toward shorter wavelengths and water temperatures are colder than at the sea surface. In addition, we have not established the extent to which water temperatures predicted from $U^{k'}_{37}$ values are biased by the seasonality of the source input to sediments. Accurate palaeoclimatic interpretation of SST curves constructed from the down-core sediment record for $U^{k'}_{37}$ values will necessitate a detailed knowledge of what upper-ocean water temperature is recorded by the internal composition of this biomarker series. □

Benthic–pelagic coupling in a deep-sea benthic community

Gerhard Graf

Institut fur Meereskunde, Düsternbrooker Weg 20, 2300 Kiel, FRG

SEASONAL productivity in shallow waters elicits a seasonal pattern of activity in the benthic community[1]. This implies a very rapid response to fluctuations in the food supply to the benthos. Although there is a seasonal component to oxygen consumption on the deep-sea floor[2] and a rapid response of epibenthic foraminifera[3] and other microorganisms to influx of phytodetritus[4], the timescale of the response of organisms that inhabit the sediment itself has not been established. Here I present evidence that the response by a deep-sea benthic community to a pulse of natural organic matter occurs within days. In terms of activity and biomass, this rapid response was evident to a sediment depth of 9 cm.

The investigation was carried out on the Vøring plateau off the Norwegian continental margin at a water depth of 1,430 m (67°39′1″ N, 05°48′3″ E). The station was close to an escarpment at the foot of a 200 m-high ridge, where a multiple-sample sediment trap was moored during the experimental period[5]. Box corer samples were taken during the spring of 1986 and one during the summer of 1985.

From 24 May to 4 June, there was a sudden increase in chlorophyll *a* (ref. 5; Fig. 1) within the sediment itself, to a depth of 9 cm. During the rest of June there was a decrease in the concentration of chlorophyll *a*. This pattern was created by a pulse of faecal pellets which, especially at the end of May, were mainly derived from the copepod *Calanus finmarchicus*. Pellets accounted for 92% of the total carbon in the settling particles[6]. The ratio of particulate organic carbon (POC) to chlorophyll *a*-equivalent = 161 and the ratio of POC to particulate organic nitrogen (PON) = 7.2. These ratios were indicative of high quality food because they are close to those of fresh phytodetritus. During July there was an increase in the particulate influx of POC from 3 to 45 mg carbon $m^{-2}\,d^{-1}$ (ref. 7). The same pattern was observed ~100 miles further north in the Lofoten Basin[8]. During July, however, there was a decrease in food quality, with POC: chlorophyll *a*-equivalent > 3,000, and POC:PON > 10. Consequently, the much higher POC flux caused only a minor increase of chlorophyll *a* within the upper layer of the sediment. The chlorophyll *a* pattern in the sediment (Fig. 1) thus reflected the same sedimentation pattern as that found in the trap. The integrated pellet pulse produced an increase in the concentration of chlorophyll *a* to 3.3 μg cm^{-2}, which was 82 times more than that collected in the trap. This agreed, however, with the estimated loss of 3.0 μg chlorophyll *a* per cm^{-2} from the water column during the same period[7]. The discrepancy was caused by the poison in the trap, in this case chloroform, which extracted pigments from the sampled material and hence led to a gross underestimate of the input of chlorophyll *a*.

The chlorophyll *a* profile on 4 June implies that the pellets were incorporated into the surface sediment at a very rapid rate (> 1 cm d^{-1}), which was much more than could be expected for deep-sea bioturbation. The reason for this is that particle transport was not an effect of reworking, as recently described for echiurids[9], but a unidirectional transport of food particles down a burrow by the sipunculans *Nephasoma* sp.. Therefore, it was inappropriate to apply Fick's law and calculate an apparent diffusion coefficient. These organisms build up to 11,000 burrows per m^2 in this area[10]. With their 6-mm-long introvert grazing on the sediment, the sipunculans can reach a 100 % coverage of the surface. At a sediment depth of 9 cm ~30 burrows of *Nephasoma* sp. merge; from here one burrow leads off to a depth of more than 50 cm (ref. 10). Thus specimens were able

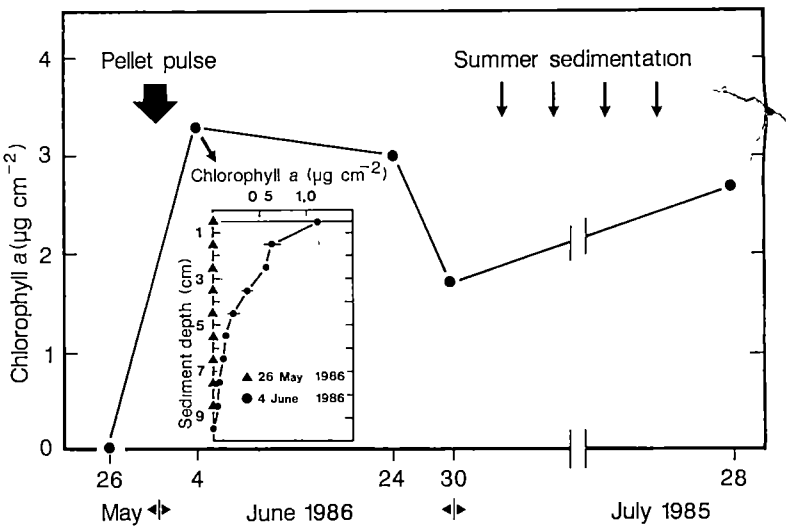

FIG 1 Concentrations of chlorophyll *a* in the sediment during spring 1986, collected with a box corer. The depth profiles indicate the fast penetration of pigments into the sediment The integrated concentrations of chlorophyll *a* depict sedimentation of a pellet pulse deriving from *Calanus finmarchicus* grazing on the spring bloom

to transport pelagic material, which settled on the sediment surface like foraminiferal shells or coccolithophores, quickly into the underlying geological strata.

The concentration of ATP in the sediment also responded to the pellet pulse (Fig. 2). At the end of May, concentrations of ATP were low and comparable to those of the North Pacific[11]. A remarkable subsurface maximum was found, however, which corresponded to the depth range of the sipunculans[10]. After the input of food, an increase in ATP was visible to a depth of 10 cm, but was also especially pronounced at the sediment surface, where the elevated level persisted until 24 June. In two of the four cores a second ATP maximum was found between a depth of 6 and 8 cm. It corresponded to a horizontal burrow system of an enteropneust, *Stereobalanus canadensis*[12], which creates a special microhabitat where the wall lining is intensively explored by small agglutinated foraminifera (Jensen, personal communication). An ATP maximum was not found in every core because the subsurface burrow system covered at most 50 % of the area.

In shallow waters, changes in the concentrations of ATP may be used to calculate benthic production. Off the Vøring plateau the ATP increase may have also been derived from (1) microorganisms attached to the pellets, and (2) new ATP produced by organisms that had activated their metabolism after periods of starvation or dormancy. In the latter case there was no constant ratio between biomass and the concentration of ATP.

Shipboard measurements of oxygen consumption (Fig. 3) agreed with the depth-dependent rates measured *in situ* for the north-west Atlantic[13], indicating that pressure effects of bringing the samples from the ambient water depth were not severe. No immediate response to the pellet pulse was detected in early June, indicating that either a shorter event occurring later in May had been missed — an explanation suggested by laboratory simulation of sedimentation events[14] — or the response was slow and did not occur before 30 June. Such a late response, however, would be indistinguishable from the effect of an increase in summer sedimentation.

We measured heat production by direct microcalorimetry[15] at −0.5 °C, close to the *in situ* temperature of −0.7 °C (Fig. 4). Heat production in sediments is of mainly biological origin[16] and is a direct measure of energy flow[14]. The heat production profile from 24 June shows that biological activity in the sediment was by no means restricted to the upper few millimetres of the sediment, as suggested by oxygen microprofile measurements in other deep sea areas[17], but penetrated substantially below. If decomposition of organic matter is spread over a sediment depth of 9 cm — as was the case here — and is not supplied by a steady flow of particles but by seasonal pulses, a significant time lag between biological effects in the sediment and oxygen consumption at the surface is to be expected.

The response time of the benthic community was less than eight days. Future investigations of benthic-pelagic coupling in the deep sea have to be carried out on short timescales and include the whole sediment layer influenced by macrofauna. The fast deep-reaching response indicates that nutrient profiles should also be influenced. Another consequence of these results is that because pelagically produced particles arriving at the sea floor in association with a food pulse are deeply mixed with older material, they have little chance of becoming recorded in the sediment surface. □

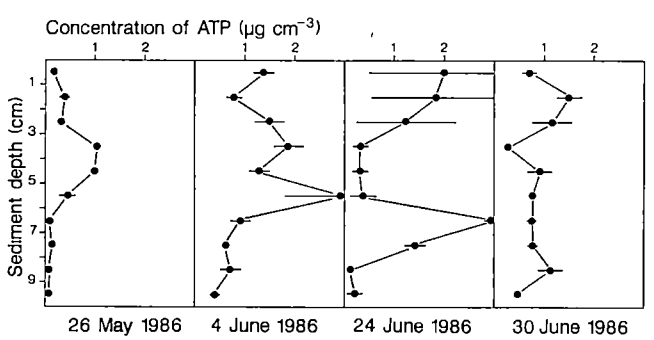

FIG. 2 The concentrations of ATP in the sediment ($n=5$) increased after the pellet pulse, especially in the surface layer. Two subsurface maxima correspond in sequence to the occurrence of sipunculids and enteropneusts, respectively.

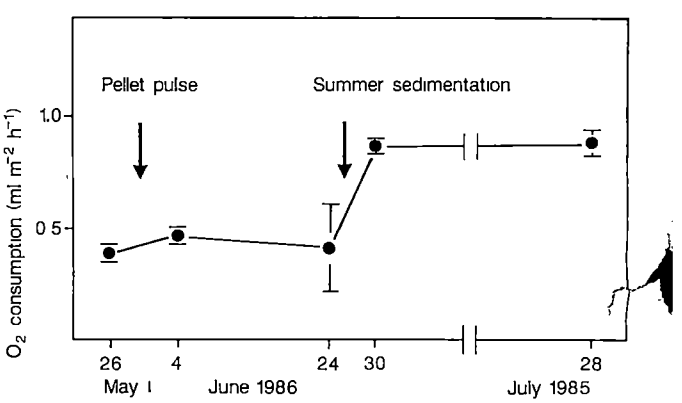

FIG 3 Oxygen consumption of the sediment ($n=3$) did not show an immediate response to the food supply.

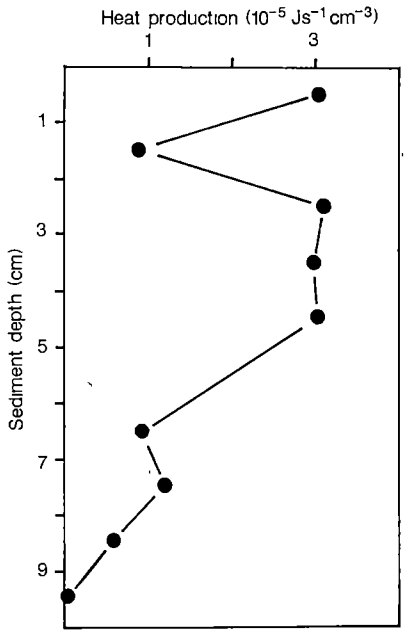

FIG. 4 Heat production in the sediment on 24 June, the decomposition of organic matter mainly occurs in the surface layer and in the subsurface layers influenced by the sipunculids.

A direct nicotinic receptor-mediated inhibition recorded intracellularly *in vitro*

Linda A. Wong & Joel P. Gallagher

Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, Texas 77550, USA

ACETYLCHOLINE activates both nicotinic and muscarinic receptors in the central nervous system[1]. Although the action of acetylcholine at muscarinic receptors has been well characterized, relatively little is known at the cellular level concerning nicotinic receptor stimulation in brain. Central nicotinic receptors have been implicated in Alzheimer's disease[2], seizure activity[3], the generation of slow-wave theta rhythm in the hippocampus[4] and the potential abuse liability of nicotine[5]. At the neuronal level, nicotinic agonists have been most often associated with postsynaptically mediated excitation and membrane depolarization at various sites, including Renshaw spinal motoneurons[6], locus coeruleus[7] and the medial habenular nucleus[8]. Nicotine acting presynaptically can produce either excitation or inhibition indirectly through the release of endogeneous transmitters or modulators[9–12]. Whereas a direct inhibitory effect of nicotine has been suggested by one *in vivo* extracellular recording study in rat cerebellar Purkinje neurons[13], the mechanism(s) underlying this action is not yet known. We now report our findings obtained using *in vitro* intracellular methods in a submerged brain slice preparation in which application of nicotinic agonists to rat dorsolateral septal neurons reveal a direct membrane hyperpolarization mediated by an increase in potassium conductance.

The dorsolateral septal nucleus (DLSN) lies within the septohippocampal circuitry and is believed to play a part in integrating afferent electrical activity arising from the hippocampus before terminating in the medial septum/nucleus of Diagonal Band of Broca complex (MS/DBB)[14–16]. The MS/DBB is, in turn, involved in the generation and maintenance of hippocampal theta rhythm[17–19].

Several lines of evidence point to a role for afferent cholinergic pathways in the function of lateral septal nuclei. Acetylcholinesterase staining[20,21] as well as nicotinic and muscarinic binding sites[22–25] are evident in this region. Additionally, immunohistochemical studies indicate that the DLSN receives a cholinergic innervation from the laterodorsal tegmental[26] and pedunculopontine nuclei[27]. Consistent with these anatomical findings, electrophoretic application of acetylcholine (ACh) *in vivo* depresses spontaneous neuronal activity and electrically evoked field potentials in lateral septum, suggesting that ACh may serve to inhibit synaptic transmission in this region[28,29]. Also, recent studies from this laboratory, using *in vitro* intracellular recording methods, have provided direct evidence that neurons in the DLSN are cholinoceptive[30,31]. These latter findings indicate that cholinergic agonists produce effects which are mediated in part at pre- and postsynaptic M_1 muscarinic receptors in the DLSN. The responses to non-selective cholinergic agonists such as ACh or carbachol, however, were not completely antagonized by atropine, implying the presence of nicotinic receptors. In this study we investigated the membrane effects and ionic mechanism underlying nicotinic receptor activation in the DLSN using ACh (tested in the presence of 5 μM atropine), nicotine, and 1,1-dimethyl-4-phenylpiperazinium (DMPP) as specific agonists.

Intracellular recordings were obtained from the DLSN neurons contained within a submerged brain slice, continuously superfused with Krebs buffer. Data were collected from 105 DLSN neurons which exhibited a resting membrane potential of -59.9 ± 0.4 mV (mean ± s.e.m.; $n = 55$), a membrane time constant of 29.9 ± 2.1 ms ($n = 30$), and an input resistance of 99.6 ± 4.9 MΩ ($n = 30$) The method of pressure ejection was frequently used in this study to apply nicotinic agonists to minimize receptor desensitization resulting from bath application of agonists. DMPP was used as a prototypic nicotinic agonist in our study as it was found to be more potent and less desensitizing than nicotine in our preparation (unpublished data). Similar observations regarding differences in the potency between DMPP and nicotine have been noted in studies of the peripheral ganglia[32].

Application of DMPP (5–10 mM) by pressure-ejection produced a membrane hyperpolarization (6.0 ± 0.4 mV) associated with decreased membrane resistance and cessation of spontaneous firing in 43 out of 61 neurons (Fig. 1*a*, top). This membrane hyperpolarizing response could be mimicked by pressure application of ACh (100 mM) in four out of eight neurons (4.7 ± 1.2 mV; Fig. 1*a*, middle) or nicotine (100 mM) in eight out of sixteen neurons (6.0 ± 1.2 mV; Fig 1*a*, bottom). In addition, a small amplitude depolarization (1–2 mV) occasionally followed the membrane hyperpolarization induced by nicotine (Fig. 1*a*, bottom). Superfusion of DMPP (0.1–100 μM;

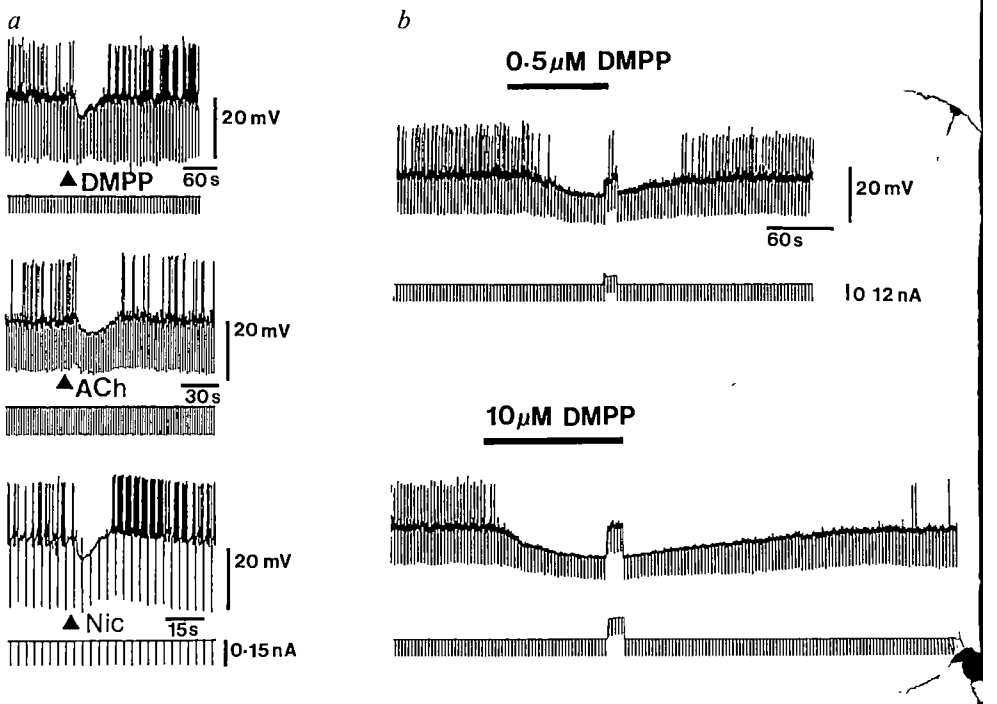

FIG. 1 Effects of DMPP, ACh and nicotine (Nic) on the membrane potential and input conductance of DLSN neurons. *a*, Pressure application of DMPP (10 mM, top); ACh (100 mM, in the presence of 5 μM atropine to block muscarinic receptors, centre); and Nic (100 mM, bottom) produced membrane hyperpolarizations (4–6 mV) lasting 20–60 s. A small amplitude membrane depolarization follows the prominent Nic-induced membrane hyperpolarization The neurons resting membrane potential was −56 mV (top), −59 mV (centre), and −58 mV (bottom), respectively. *b*, The effect of DMPP is concentration-dependent. Bath-applied DMPP (0 5 μM) produced a 7 mV membrane hyperpolarization accompanied by decreased input resistance. Superfusion of 10 μM DMPP, in the same cell, produced a larger amplitude hyperpolarization (12 mV). The decrease in membrane resistance and inhibition of firing persisted during return of membrane potential to control level from the peak of hyperpolarization by injection of a depolarizing DC current. Upward deflections in upper trace represent action potentials, whereas downward deflections represent voltage responses to constant current injection, shown in lower trace. Resting membrane potential, −60 mV.

METHODS Rat septal brain slices were prepared as previously described[35]. Male Sprague-Dawley rats weighing 150–250 g were decapitated, the brain rapidly dissected out and placed in cold Krebs solution of the following composition (mM) NaCl, 117; KCl, 4 7; $MgSO_4$, 1.2; $CaCl_2$, 2.5; NaH_2PO_4, 1 2, glucose, 11.5; $NaHCO_3$, 25; pre-bubbled with 95% O_2 and 5% CO_2. Transverse blocks of tissue containing the septum were serially cut on a Vibroslice (Campden Instrument) into 500 μm sections. A single slice was placed in the recording chamber and superfused with oxygenated Krebs solution warmed to 32 ± 1 °C. Conventional intracellular recording methods were employed using glass micropipettes (75–110 MΩ) filled with 4 M potassium acetate or 2 M potassium chloride Hyperpolarizing current pulses (0 1–0.15 nA) were injected into the recording pipette by commands generated through an Axoclamp (Axon Instruments) amplifier Orthodromic stimuli were delivered with square-wave pulses (5–20 V, 0 15 ms) through concentric bipolar electrodes placed focally within the DLSN. DMPP (5–10 mM), ACh chloride (100 mM) and nicotine hydrogen tartrate (100 mM) were applied by pressure-ejection (15–20 psi, 20–50 ms, Picospritzer, General Valve Corporation) through a glass micropipette (tip diameter 20–35 μm) positioned in solution within 200–300 μm from the recording electrode above the surface of the slice. By this method of application the agonist was diluted by a factor of about 1/100. All other drugs were freshly dissolved in Krebs buffer and applied by superfusion Atropine (5 μM) was included in the bathing medium to block muscarinic receptor-mediated effects during ACh-application. Only one neuron was obtained from each brain slice for pharmacological testing.

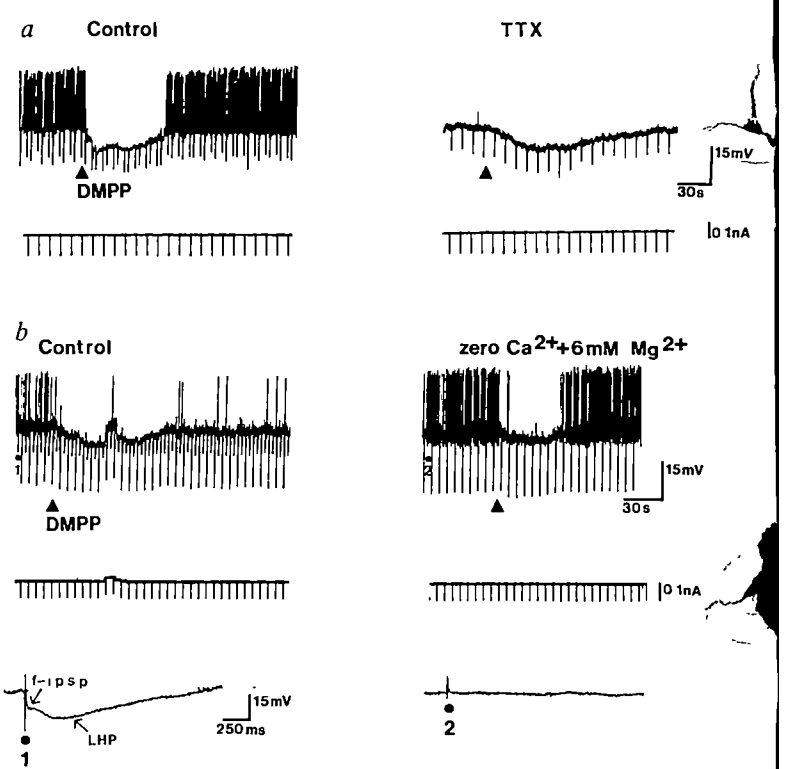

FIG 2 Postsynaptic site of DMPP-induced membrane hyperpolarization. Slices were treated with TTX (1 μM) or zero Ca^{2+} plus 6 mM Mg^{2+}, which completely blocked orthodromically stimulated synaptic responses after 1 and 4 min, respectively Pressure-applied DMPP (10 mM) produced a membrane hyperpolarization that persisted in (*a*) TTX (1 μM) or (*b*) zero Ca^{2+} plus 6 mM Mg^{2+}. The evoked synaptic potentials are represented by the additional set of downward deflections in the control voltage traces In *b*, the bottom panel shows expanded traces (labelled 1 and 2) of the synaptic waveform evoked by orthodromic stimuli 20 V, 0.15 ms). Control synaptic waveforms (labelled 1) consist of a fast inhibitory potential (*f* − i p.s.p.) mediated mainly by $GABA_A$ receptors and a late hyperpolarizing potential (LHP), which is mediated in part by GABA acting on $GABA_B$ receptors[35]. Both *f* − i.p.s.p. and LHP were completely abolished in calcium-free medium (see label 2), leaving a stimulus artefact denoted by the short vertical deflection in the trace. Further increase of stimulus intensity to a supramaximal level (60 V) did not restore either the *f* − i p.s.p. or LHP potentials, indicating a complete blockade of synaptic transmission in calcium-free medium.

Fig. 1*b*) also produced membrane hyperpolarization (2–13 mV) in 17 of 20 cells tested. The amplitude and duration of the hyperpolarization depended on the concentration of DMPP applied.

To determine whether the nicotinic agonist-induced membrane hyperpolarization resulted from a direct action on the postsynaptic membrane, DMPP was applied in the presence of either tetrodotoxin (TTX; 0.1–1 μM) or a modified Krebs solution containing no added calcium and 6 mM magnesium (zero Ca^{2+}, 6 mM Mg^{2+}) which blocked synaptic transmission (Fig. 2). Pressure-applied DMPP produced a membrane hyperpolarizing response that persisted in TTX ($n = 8$; Fig. 2*a*) or zero Ca^{2+}, 6 mM Mg^{2+} medium ($n = 4$; Fig. 2*b*), indicating that DMPP was activating receptors located directly on the neuron studied. It is interesting to note that although the response to DMPP persisted in zero Ca^{2+}, 6 mM Mg^{2+} medium (Fig. 2*b*), at which time orthodromic synaptic responses were completely abolished (Fig. 2*b*, bottom panel), the amplitude of the DMPP-induced response appeared attenuated. Although the depression of the DMPP-mediated hyperpolarization may be due to an incomplete block of synaptically released neurotransmitter, it is more probable that the postsynaptic response to nicotinic agonists in DLSN is in some way dependent on Ca^{2+} or blocked by Mg^{2+}. Preliminary results using intracellular injection of the calcium chelator, EGTA, reveal that the DMPP-induced membrane hyperpolarization is completely blocked (data not shown).

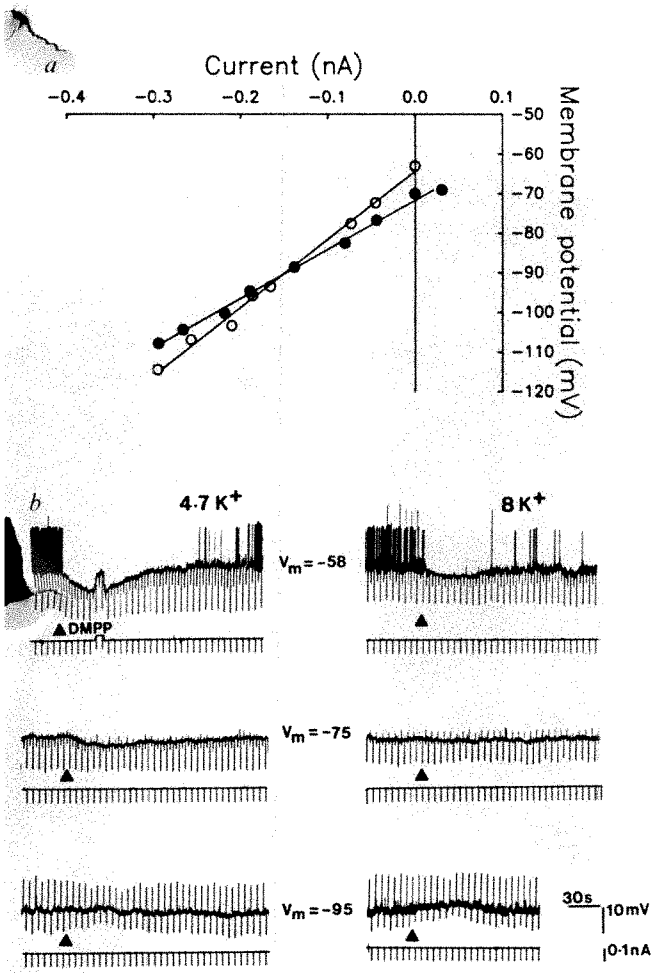

FIG. 3 Potassium dependence of DMPP-induced membrane hyperpolarization. *a*, A plot of current-voltage relationships obtained before application of DMPP (open circles) and at the peak of the response to superfused DMPP (10 μM; closed circles) revealed a reversal potential of −90.5 mV. Lines were calculated using linear regression. *b*, DMPP was pressure-applied at holding potentials of either −58, −75 or −95 mV in 4.7 mM and 8 mM external K^+ solutions. In 4.7 mM external K^+, the DMPP-induced membrane hyperpolarization exhibited an apparent reversal at −95 mV which was shifted to −75 mV in 8 mM external K^+. Evoked responses are represented by the additional sets of downward and upward deflections.

The membrane hyperpolarizing action of DMPP, ACh, and nicotine was accompanied by a decrease of input resistance indicating an increase of ionic conductance. This agonist-induced hyperpolarization was reproducible whether the electrode contained potassium chloride ($n = 3$) or potassium acetate ($n = 72$), suggesting that Cl^- ions were not involved. A plot of current-voltage relationships recorded before application of DMPP and at the peak of the DMPP-induced membrane hyperpolarization (Fig. 3*a*) revealed a reversal potential of -91.2 ± 1.9 mV ($n = 8$), a value close to the equilibrium potential for K^+ ion. To obtain further evidence that the potential changes were due only to changes in K^+ conductance, DMPP was applied in the presence of altered K^+ ion concentration. The DMPP-induced membrane hyperpolarizing response reversed at -92 ± 1.5 mV ($n = 3$) and -77 ± 1.2 mV ($n = 3$) in 4.7 mM and 8.0 mM K^+, respectively (Fig. 3*b*). In each case, recovery followed wash-out of 8 mM K^+ and the reversal potential after return to control 4.7 mM K^+ was -91 ± 1.4 ($n = 3$). This shift in the reversal potential of the hyperpolarization was close to that predicted by substitution of the altered extracellular K^+ concentration in the Nernst equation and provides strong evidence for the role of K^+ ions in mediating the membrane hyperpolarization produced by DMPP.

Our results demonstrate that ACh, nicotine and DMPP have direct actions on DLSN neurons, as indicated by persistence of the nicotinic-mediated membrane hyperpolarization in TTX or zero calcium, high magnesium solutions. To our knowledge, this is the first demonstration of a direct nicotinic receptor-mediated membrane hyperpolarization and associated inhibition of neuronal activity recorded intracellularly from a mammalian neuron. In addition, we have performed pharmacological tests to characterize this nicotinic-mediated response in the DLSN neurons (data not shown). These findings indicate that the membrane hyperpolarization produced by pressure-applied DMPP or nicotine can be effectively blocked by prior treatment of the slice with superfused mecamylamine (50–100 μM), a ganglionic nicotinic antagonist, and κ-bungarotoxin (0.7–1.0 μM), a snake venom toxin that has been shown to block neuronal nicotinic receptors[33,34].

As neurons in the DLSN are known to project to the MS-DBB complex[14–16] and the latter is involved in the generation and/or maintenance of hippocampal theta rhythm[17–19], drugs or transmitters that alter the neuronal activity of DLSN may also influence MS/DBB activity and correspondingly, theta rhythm. The presence of cholinergic innervation to the lateral septum from brain stem nuclei[27,28] also raises the possibility that brain stem areas may be involved in the modulation of septohippocampal theta rhythm through cholinergic mechanisms in the DLSN. It is possible that inhibition of DLSN neurons through nicotinic receptor stimulation may be one of the mechanisms by which ascending control of theta activity is facilitated. □

Mutant *Drosophila* embryos in which all cells adopt a neural fate

Marc Bourouis, Pascal Heitzler, Mariame El Messal & Pat Simpson*

Laboratoire de Génétique Moléculaire des Eucaryotes du CNRS, Unité 184 de Biologie Moléculaire et de Génie Génétique de l'INSERM, Faculté de Médecine, 11 Rue Humann, 67085 Strasbourg Cédex, France

IN the *Drosophila* embryo, early developmental decisions lead to all cells adopting one of several initial fates, such as those characteristic of the germ layers. The central nervous system is formed subsequently from the neurogenic region of the ectoderm, in which progenitor cells of the neuroblasts and ventral epidermis are intermingled[1,2]. Two classes of genes govern the segregation of neuroblasts and peripheral sensory organs. The pro-neural[3] class of genes, for example, the achaete-scute complex, participates in the initial decision to make each uniquely positioned neuroblast or sensory organ[4–7], but are initially expressed in groups of cells[8,9]. The segregation of a neuroblast or sensory organ from an equivalent group[10] of equipotential cells involves a mechanism of lateral inhibition whereby the future epidermal cells are prevented from engaging in the primary dominant neural fate[2,11–15]. In the absence of this inhibitory signal, all cells of the group will become neural by default[1,16–19]. The neurogenic class of genes is thought to mediate these cell interactions[20]. Here we report that cells in embryos mutant for *shaggy* which are unable to adopt any of the early initial fates, instead develop neural characteristics.

* To whom correspondence should be addressed.

Shaggy (*sgg*) null embryos produced by a loss-of-function mutation in both the female germ line and the zygote (see Fig. 1) were abnormal at a stage as early as syncitial blastoderm, when no clear cortical cytoplasm is evident in living embryos. Histological sections (Fig. 1) showed that nuclei migrate to the periphery but that cellularization is delayed. At the blastoderm stage the embryos did not form a continuous sheet of elongated cells. Instead cellularization was disordered, leading in some cases to embryos with gaps in the blastoderm. Furthermore, the cells were abnormally small and round. None of the normal events of gastrulation occurred and the embryos showed no sign of the development of an ectoderm, mesoderm or endoderm. Cells started to divide and their progeny accumulated in the interior of the egg. Over several hours the disorganized embryos became filled with small round uniform cells which resembled the ganglion mother cells that normally arise in the central nervous system. The neural character of the cells was confirmed using antibodies specific for neuronal cells. As shown in Fig. 2, most, if not all, of the cells stained positively with both an antibody against a neuronal cell-surface epitope, anti-horse-

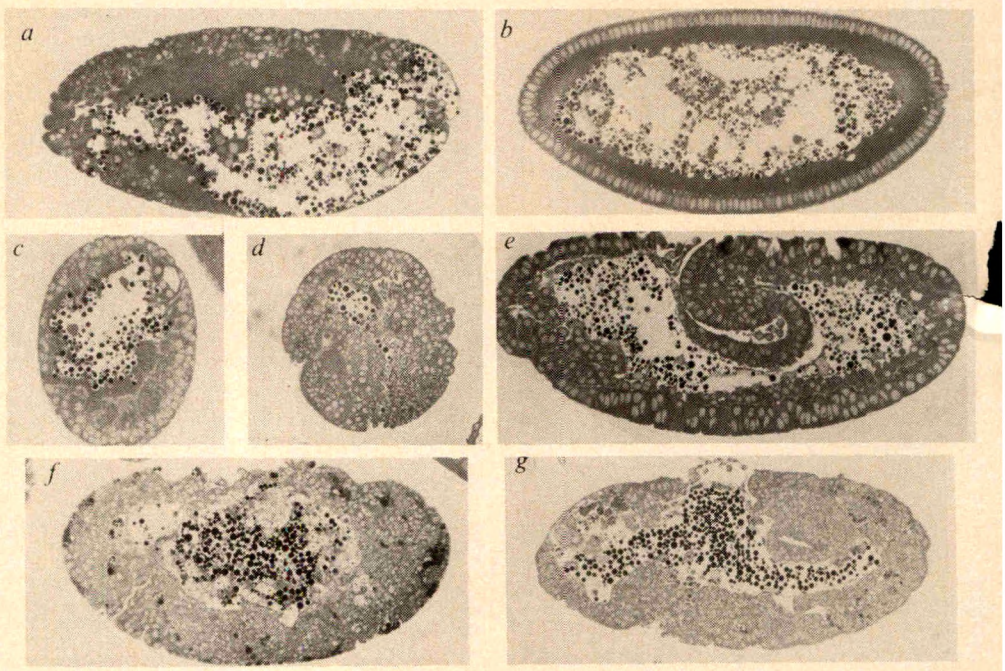

FIG. 1 Histological sections of mutant *sgg* embryos. *a*, A *sgg* null embryo showing the disordered cellularization observed at blastoderm. Note the abnormal segregation of cortical cytoplasm and yolk, the round peripheral cells and the presence of nuclei not incorporated into cells. *b*, Paternally rescued embryo showing an almost normal cellular blastoderm. Nuclei lagging behind those at the periphery are frequently encountered in these embryos. *c*, *d*, Transverse sections of *sgg* null embryos. The embryo in *c* was ~4-h-old, a stage at which normal embryos have gastrulated. Note that the cells around the entire periphery are internalizing. The embryo in *d* is slightly older, and smaller cells are accumulating interiorly. *e*, Paternally rescued embryo at the end of the rapid phase of germ-band extension. These embryos undergo normal gastrulation and the three germ layers are visible. This implies that eggs made in the absence of the maternal *sgg* product have normal polarity, that is, the fate map is not changed. *f*, A *sgg* null embryo at a later stage, about the same age as the embryo in *g*. A study of serial sections shows that these embryos are like bags of marbles, being filled with round cells, interrupted only by clumps of unconsumed yolk. *g*, Paternally rescued embryo at the beginning of germ-band retraction. Hyperplasia of the developing central nervous system can be seen.

METHODS. Germ-line clones mutant for *sgg* (3B1) were generated by X-ray induced mitotic recombination. Irradiated *sgg*/*ovo*^{D1} (ref. 26) females were crossed with wild-type males to give progeny, half of which receives a paternally derived *sgg*$^{+}$ allele. Observations of living and sectioned embryos shows a bimodal distribution. Embryos were fixed with heptane and glutaraldehyde and processed as previously described[27]. Embryo were embedded in durcupan (Fluka, Switzerland) and semi-thin sections of 1.5–2.0 μm were stained with methylene blue. The allele *sgg*^{D127} was used for the histology but observations of living embryos and of the cuticular phenotypes of paternally rescued embryos for the alleles *sgg*^{D127}, *sgg*^{k22} and *sgg*^{b12} show identical phenotypes. Genetic analysis and preliminary molecular characterization (Yves Grau and P.S., unpublished results) indicates that both *sgg*^{D127} and *sgg*^{b12} are amorphic alleles.

radish peroxidase antibody (anti-HRP)[21], and a very early neuronal nuclear marker, monoclonal antibody mAb44C11[22], which stains the differentiating neurons in the wild-type embryo.

The defective cellularization observed in *sgg* null embryos implies that the *sgg* gene has an early activity, perhaps during cellularization itself. Note, however, that there is no absolute requirement for the *sgg* gene product for vital cellular functions; mutant cells are viable in the germ line, larva or imaginal discs, and can proliferate normally[23].

We partially rescued the null phenotype of *sgg*-mutant embryos, selectively allowing either maternal or zygotic gene expression. This revealed the effects of *sgg* mutants on other developmental processes. The zygotically rescued embryos formed an almost normal blastoderm and gastrulate (Fig. 1). The embryos first deviated conspicuously from wild-type embryos at neurogenesis when a greater number of neuroblasts segregate.

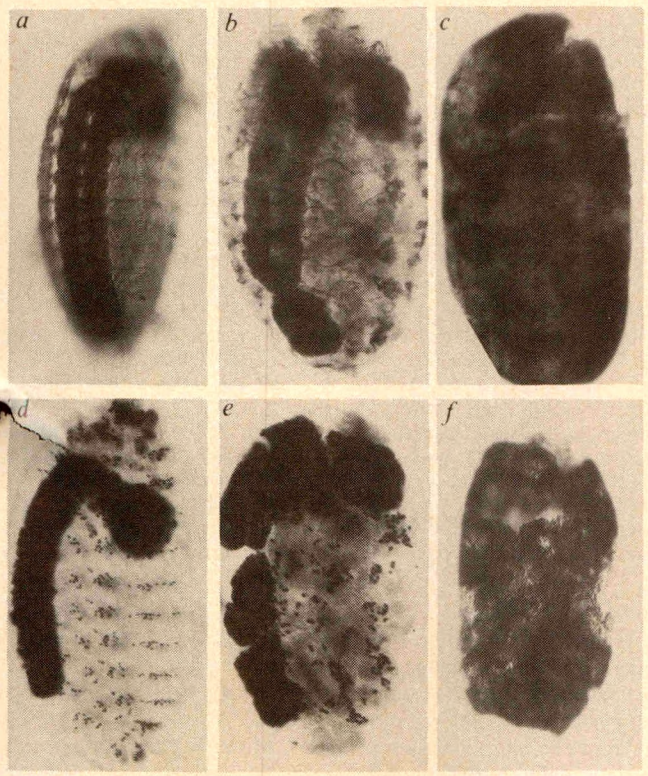

FIG. 2 Neural-specific immunocytochemical staining of *sgg* embryos selected at a stage when development of the central nervous system is complete. Left, wild-type embryos; middle, paternally rescued *sgg* embryos; right, *sgg* null embryos. *a, b, c*, Embryos stained with anti-HRP antibody[21] (ventro-lateral view). *d, e, f*, Embryos stained with mAb44C11[22] (lateral view). In the null embryos most, if not all, cells stain positively for both markers. In the paternally rescued embryos staining of both the central nervous system and the peripheral nervous system is evident. Enlargement of the ventral nerve cord reveals hyperplasia and also in *b*, local hyperplasia of the scolopidia of the chordotonal organs at the periphery.
METHODS. Mutant embryos, obtained as described in Fig. 1, were treated as described previously[7], using anti-HRP antibody (Sigma) and the mAb44C11. For mAb44C11 a biotinylated goat anti-mouse IgM (Amersham) together with the ABC kit (Vector Labs) was used for detection.

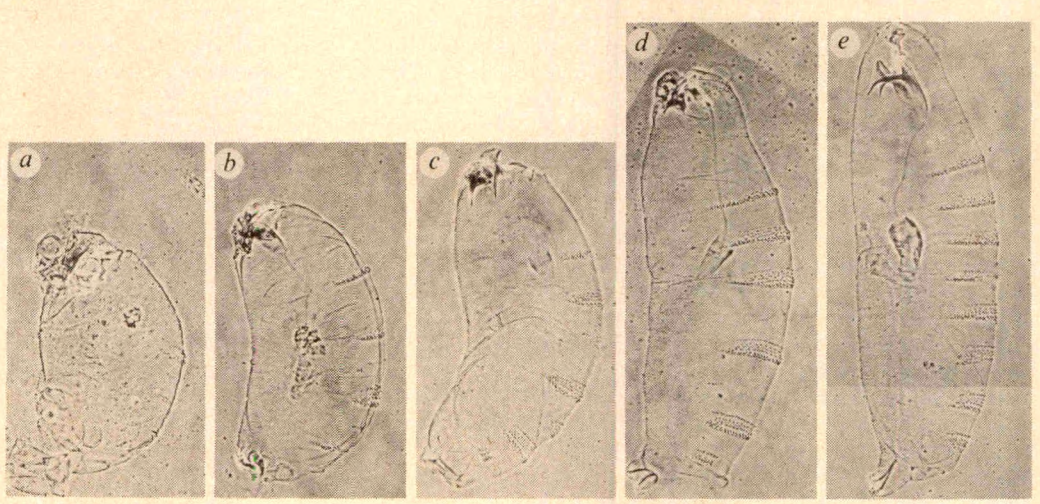

FIG. 3 Cuticular preparations of zygotically rescued *sgg*-mutant embryos. Females with a mutant germ line (see Fig. 1) were crossed either with +/*Y* males (*a*) or +/w^+Y, sgg^+; dup(1; 2)w^{+70h}, sgg^+/+ males (*b, c, d* and *e*). Paternally rescued embryos from the first cross secreted a very short cuticle that was organized in the form of a tube (*a*). Embryos of this genotype display neural hyperplasia (Figs. 1 and 2). Complete hyperplasia found locally would be expected to cause holes in the ventral cuticle, as in the neurogenic mutants[16,17]. The presence of a continuous cuticle, therefore, indicated that the remaining epidermal cells were distributed along the entire length of the embryo. This implies an even distribution of the multitudinous neuroblasts, a situation reminiscent of the even spacing of bristles seen in the mutant imaginal epidermis[15]. The cuticle displayed a lawn of dorsal hairs, but ventrally most of the denticle belts were lacking. Superficially this phenotype resembled that of embryos mutant for *naked*[28], a gene of the segment polarity class. From the second cross zygotes may receive one or two paternal copies of sgg^+, and in male embryos these will be dosage compensated. These embryos show more effective rescue (*b–e*). The embryo in *e* had an almost normal cuticular pattern. Progressively more bands of ventral denticles appeared, beginning at the lateral margin. The pattern of rescue showed a marked regional preference and occurred in an alternating segment mode, the odd-numbered segments appearing before the even-numbered ones. Zygotic loss of *sgg* did not lead to abnormal segmentation of the cuticle (see Fig. 4). Therefore, the defects observed, which were caused by maternal loss, imply that the segmentation process requires a threshold level of a probably evenly distributed maternal product. Further investigation is necessary to determine whether the anomalous segmentation reflects a requirement for *sgg* specific to this patterning process or a more general requirement in the cells of the epidermis.

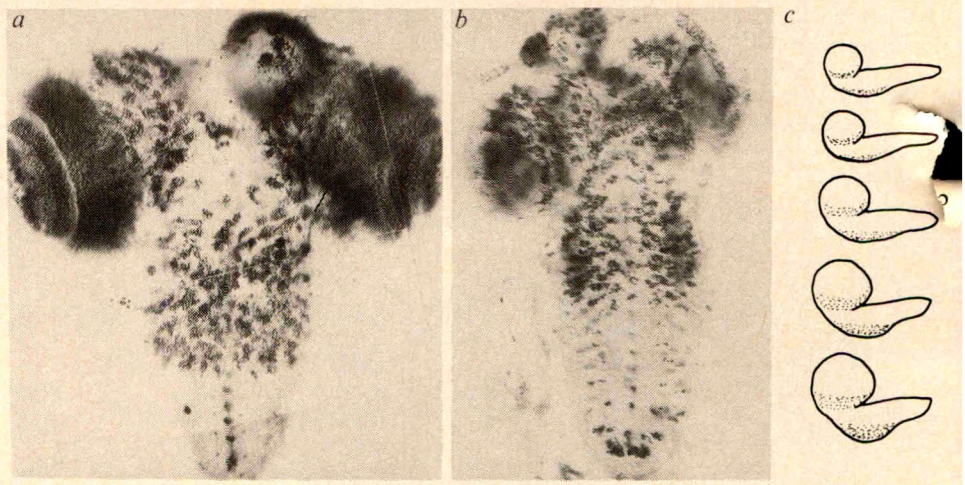

FIG. 4 Growth of larval nervous systems in maternally rescued *sgg* mutant zygotes. When derived from females with a wild-type germ line, mutant animals hatched as larvae. They displayed abnormal growth of the nervous system. *a, b*, Larval central nervous systems of late third-instar wild-type and mutant siblings labelled by incorporation of 5-bromodeoxyuridine to reveal neuroblasts and their progeny (dorsal view). Such dividing cells produce the future adult central nervous system. The cell clusters in these figures represent the progeny of individual neuroblasts[29]. Cell counts from a number of such preparations and a parallel study of staged toluidine-blue-stained preparations[29] (data not shown) showed that similar numbers of neuroblasts were present in mutant and wild-type central nervous systems. In the mutant, however, they divided less. This led to the lack of differentiation of the optic lobes and the reduced size of the thoracic neuromeres (*b*). Growth of the imaginal discs was also poor in these animals. Furthermore, the larval stages were prolonged and the animals died as larvae or poorly contracted pupae. Preliminary data (not shown) indicate that these defects may stem from a malfunctioning of the larval brain or ring gland, or from both. All of these defects were progressively improved if the embryos had been supplied with increased amounts of maternal sgg^+ gene product. *c*, Schematic drawings (derived from camera-lucida drawn shapes) of third-instar larval nervous systems (lateral view) of mutant animals derived from mothers carrying 1, 2, 3 or 4 doses of sgg^+, from top to bottom. The central nervous system shown at the bottom was from a wild-type sibling. Gross morphological inspection showed improved growth, notably of the optic lobes and thoracic neuromeres. We interpret these results to mean that increasing amounts of maternally-supplied *sgg* gene product can lead to a more functional larval brain, better able to support further larval growth.

METHODS. Females were of the following genotypes: (1) $FM6/sgg^{D127}$ *w s*; (2) *C(1)DX/Y*; (3) *C(1)DX/Y*; dup(1; 2)w^{+70h}, $sgg^+/+$; (4) *C(1)DX/Y*; dup (1; 2) w^{+70h}, $sgg^+/+$; dup (1; 3) w^{+67k27}, $sgg^+/+$. These were crossed to $sgg^{D127}w\ s/w^+Y$, sgg^+ males. The resulting mutant zygotes (*w*) could be recognized by their white malpighian tubules. *a, b*, Larval nervous systems from female and mutant male siblings from cross with females of genotype 2. Labelling of dividing cells and their progeny was as described previously[29]. Larvae were fed for three days with BUdR, and larval central nervous systems were then dissected; detection of BUdR was by immunocytochemical staining using a peroxidase conjugate.

Staining with neuronal markers revealed neural hyperplasia (Fig. 2). This phenotype is not unlike mutants of the neurogenic class. The embryos could differentiate to give cuticle but were short. Increased amounts of zygotically derived *sgg*-gene product revealed cuticular defects characteristic of segmentation mutants, and could lead to an almost complete rescue of the pattern (Fig. 3). The maternally rescued embryos went through embryogenesis normally but died as defective larvae with abnormal brains (Fig. 4). These results indicate that maternally and zygotically derived gene-products must perform similar functions. Furthermore, there are formal similarities between the embryonic and imaginal phenotypes of mutants for *sgg*. The *sgg* mutation causes hyperplasia of the peripheral nervous system—that is, vast numbers of densely packed sensory bristles differentiate over the entire adult epidermis[15,24]. This phenotype resembles that of gain-of-function mutants of the achaete-scute complex[25].

Similarities are thus seen between different phenotypes of *sgg* mutants and the phenotypes of mutants of both the pro-neural and neurogenic classes. How, therefore, can the null phenotype of *sgg* be explained in terms of the known functions of the pro-neural and neurogenic gene classes? One possibility is that the *sgg*-gene product may normally serve to repress one or more of the pro-neural genes that are required for the specification of neural cells. Such target genes could be those of the achaete-scute complex. Analysis of the phenotypes of embryos doubly mutant for *achaete-scute* and *sgg* (data not shown), and gene-dose studies in the adult[15], however, demonstrate that *sgg* causes neither maternal nor zygotic derepression of genes of the achaete-scute complex. Alternatively, genes of the neurogenic class encode functions that are required for intercellular communication[20]. The requirement of *sgg* for normal bristle-cell segregation[15] and the observed cell-autonomy of the *sgg* mutant phenotype[24] suggests that *sgg*-mutant cells are independent of the inhibitory signal. A role of *sgg* for lateral inhibition is consistent with the neural hyperplasia exhibited by the zygotically rescued embryos. Furthermore, the requirement for *sgg* in the segmentation process could also reflect altered cell communication.

In view of the different phenotypes observed, *sgg* probably interferes with some general cell property; in the absence of this property cells become neural by default rather than as the result of a specific neural regulatory switch. Although they are not defective in an essential component of the cell membrane, *sgg* mutant cells might be unable to establish normal cellular contacts. □

Restoration of normal function in genetically defective myotubes by spontaneous fusion with fibroblasts

Nirupa Chaudhari*, Rona Delay† & Kurt G. Beam*

* Department of Physiology and † Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, Colorado 80523, USA

MUSCULAR dysgenesis in mice is a genetic disease of skeletal muscle caused by the recessive mutation *mdg* (ref. 1). Muscle fibres in affected mice are paralysed because of the failure of excitation–contraction coupling[2,3]. Unlike normal myotubes in primary culture, dysgenic myotubes do not contract, either spontaneously or in response to electrical stimulation. The deficiency results from mutation of the gene for the skeletal muscle dihydropyridine receptor[4], an essential sarcolemmal component both of excitation–contraction coupling and of the slow calcium-ion channel[4,5]. It has recently been shown[6] that the addition of fibroblasts from normal (but not dysgenic) mice to cultures of dysgenic myotubes can restore spontaneous contractions in a small fraction of these myotubes, but the mechanism for this 'rescue' was not determined. In principle[7], if fibroblast nuclei were able to incorporate into myotubes, such nuclei could then supply the missing muscle-specific gene product. We have now investigated this possibility using nuclear, cytoplasmic and plasmalemmal markers. We report that the rescue to contractile ability in genetically paralysed dysgenic muscle is mediated by the previously unrecognized ability of fibroblasts to fuse spontaneously with developing myotubes.

We observed the functional rescue of dysgenic myotubes by their co-culture with cloned dermal fibroblasts from normal mice and rats, and with several fibroblast lines including 3T3, Rat2 and NRK-52E (derived from mouse embryos, rat embryos and rat kidney, respectively). The incidence of rescue varied from 2 to 28% of all myotubes, depending on the assay (spontaneous versus electrically evoked contractions), the identity of the added fibroblasts, and the time of addition of fibroblasts relative to myotube development. The addition of normal fibroblasts during myoblast proliferation was most effective; very little rescue occurred if fibroblasts were added after myotube development. Living fibroblasts seemed to be essential, because neither a medium that was conditioned by normal fibroblasts[6], nor a substrate of killed (water-lysed or ultraviolet-irradiated) normal fibroblasts, produced rescue.

To test our hypothesis that rescue reflected the fusion of fibroblasts with forming myotubes, we initially used a clonal line of 3T3 fibroblasts (ClW), which contained a stably integrated copy of the *Escherichia coli* gene for β-galactosidase[8]. The cytoplasm of ClW cells reacted positively when stained for β-galactosidase (Fig. 1*a*). When ClW cells were added to cultures of rat myoblasts or phenotypically normal (+/*mdg*?) mouse myoblasts, a small fraction of the myotubes that developed clearly contained β-galactosidase in their cytoplasm (Fig. 1*b*). In two such experiments, 1.5% of 1,600 rat myotubes and 6.0% of 650 normal (+/*mdg*?) mouse myotubes stained bright blue. Neither medium conditioned by ClW cells, nor homogenates of ClW cells, induced β-galactosidase activity in exposed myotubes. Because β-galactosidase is a protein of relative molecular mass 116,000 (M_r, 116K), it is not expected to pass through gap junctions, which have been reported to form between myotubes and non-muscle cells in culture[2,9]. The presence of β-galactosidase within myotubes, therefore, indicated that fibroblasts are able to fuse with myotubes developing in culture.

To test whether fusion of fibroblasts is necessary for the rescue of dysgenic myotubes, we added ClW cells to dysgenic myoblast cultures. Rescued dysgenic myotubes were identified by their ability to twitch in response to electrical stimulation (Fig. 1*c*). In two separate experiments, most of the rescued myotubes were stained pale to bright blue (Fig. 1*d* and Table 1). The absence of staining in 12–15% of rescued myotubes (see Table 1) implies that either β-galactosidase activity was below the level of detection in these rescued myotubes or that fusion was not required for their rescue. Thus, we established an independent assay for fusion: after staining with Hoechst 33342, mouse nuclei displayed a punctate fluorescence (Fig. 2*b*), whereas rat nuclei displayed a more homogeneous fluorescence (Fig. 2*b*, indicated by the arrow). After addition of normal rat fibroblasts to dysgenic myoblast cultures, rescued myotubes were identified by the presence of spontaneous or electrically evoked contractions. Every rescued myotube contained at least one normal rat nucleus (Fig. 2*b*, *d* and Table 1). To confirm that the rat nucleus was located inside the dysgenic myotube (rather than in a rat fibroblast adhering to the myotube), the cultures were stained with rat-specific monoclonal antibody against Thy-1.1, an antigen expressed on the surface of fibroblasts[10]. Immunostaining with this antibody confirmed that rat nuclei visually identified as being incorporated into rescued myotubes were always located within the myotubes, rather than in overlying fibroblasts (Fig. 2*e*).

Electron microscope examination of dysgenic myotubes rescued by rat fibroblasts further showed that rat nuclei were located within the sarcolemma. Such nuclei possessed an intact nuclear envelope with no evidence of fragments or invaginations of the sarcolemma in their vicinity. The electron micrographs also showed that portions of the rescued myotubes that were distant from the incorporated rat nucleus had the ultrastructural appearance of typical dysgenic myotubes[11]. For instance, myofilaments were not ordered into sarcomeres but were clumped throughout the myoplasm (Fig. 3*c*). In rescued myotubes, the organization of myofilaments into a normal sarcomeric pattern was observed, but only in the neighbourhood of the rat nucleus (Fig. 3*d*). Similar results were observed for two rescued myotubes additionally examined.

TABLE 1 Rescue of dysgenic myotubes by fusion with fibroblasts

Experiment	Type of fibroblast added	Method of assay for fusion	Frequency of marker indicating fusion (%) Rescued myotubes	Non-rescued myotubes
A	ClW	β-galactosidase	85 (n=13)	20 (n=300)
B	ClW	β-galactosidase	88 (n=16	29 (n=250)
C	Rat dermal	Nuclear morphology	100 (n=17)	31 (n=74)
D	NRK-52E	Nuclear morphology	100 (n=10)	30 (n=56)

Fusion of dysgenic myotubes with fibroblasts is required for rescue. Primary cultures of dysgenic myoblasts were co-cultured with fibroblasts as described for ClW cells in Fig. 1 legend. Primary dermal fibroblasts were cultured and cloned in our laboratory; NRK-52E fibroblasts were obtained from American Type Culture Collection, Rockville. Myotubes were tested for rescue by electrical stimulation (experiments A, B) or by observing spontaneous contractions (experiments C, D). In experiment A, myotubes were stimulated early (day 8), before any spontaneous contractions had begun in the culture. In experiment B, myotubes were grown in the presence of 10 μM tetrodotoxin to inhibit spontaneous contractions. Cultures were stained for β-galactosidase (experiments A, B) or with Hoechst 33342 (experiments C, D), as described in the legends to Figs 1 and 2, respectively.

Because co-culture with normal neurons (that is, dissociated spinal-cord cells) can restore contractile ability to dysgenic myotubes[12], it has been suggested that the primary alteration in muscular dysgenesis is extra-muscular (for example, neuronal)[13]. But the rescue obtained with neuronal co-culture could be explained by the fusion of non-muscle cells with myotubes, especially as fibroblasts and other cell types contaminate preparations of dissociated spinal neurons.

As in normal muscle, the rescued dysgenic myotubes contracted in response to electrical stimulation even under conditions that prevented the entry of calcium through voltage-gated Ca^{2+} channels (Fig. 4). Together with the observation of normal

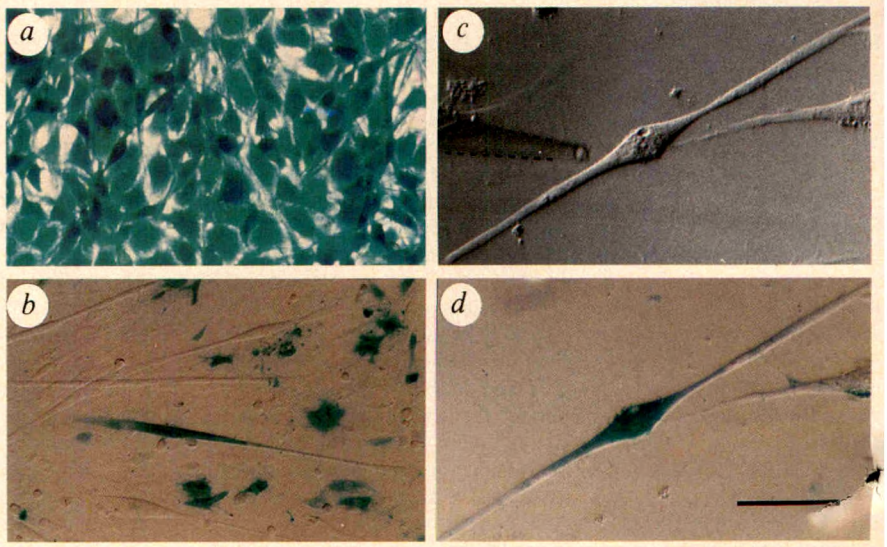

FIG. 1 Naturally occurring fusion of fibroblasts with myotubes as indicated by β-galactosidase staining. *a*, CIW is a fibroblast line of cells which contain a stably integrated bacterial gene for β-galactosidase. After fixation and histochemical staining for this enzyme, all CIW cells display a blue reaction product. *b*, CIW cells spontaneously fuse with normal myotubes. CIW fibroblasts were added to a normal rat myoblast culture one day after initial plating. Four days later, the culture was fixed and stained for β-galactosidase activity. In this experiment, ~1.5% of all myotubes had brightly stained cytoplasm, as shown. *c*, Addition of CIW fibroblasts leads to recovery of contractile ability in some dysgenic myotubes. CIW cells were added to a one-day-old dysgenic myoblast culture. On day 8 of culture, individual myotubes were tested for their ability to contract in response to electrical stimulation using an agar-plugged extracellular pipette[4]. Myotubes that responded with a normal contraction were photographed for later identification. *d*, Most rescued dysgenic myotubes clearly displayed the blue staining, which indicates that a CIW cell had fused with the myotube. After stimulation and photography for identification of rescued myotubes, cultures were fixed and stained for β-galactosidase. The myotube shown is the same as that in *c*. Scale bar: 100 μm for *a*, *c* and *d*; 200 μm for *b*.

METHODS. Myoblasts, prepared from neonatal dysgenic mice, normal mice or normal rats, were plated (at a density of ~10^5 per 35 mm dish) and cultured as described previously[17]. One day after initial plating of the myoblasts, CIW fibroblasts were added (10^4 per dish). After 2–3 days of co-culture, the serum content of the medium was changed (from 20% fetal calf to 10% horse), and excess fibroblasts were removed by treatment for 1–2 days with 10 μM cytosine arabinoside. Four to ten days after the initial plating, normal cultures were fixed and stained for β-galactosidase as described[8]. Some dysgenic cultures were maintained in the continual presence of 10 μM tetrodotoxin to prevent spontaneous contraction in the rescued myotubes, because we observed that extensive contractile activity in normal or rescued dysgenic myotubes leads to a progressive loss of β-galactosidase activity. The tetrodotoxin-treated dysgenic cultures were tested for contractile ability 9 days after initial plating; the untreated dysgenic cultures were tested 6–8 days after plating. Cultures were tested for the presence of rescued myotubes by focal electrical stimulation as described[4] and then were fixed and stained for β-galactosidase.

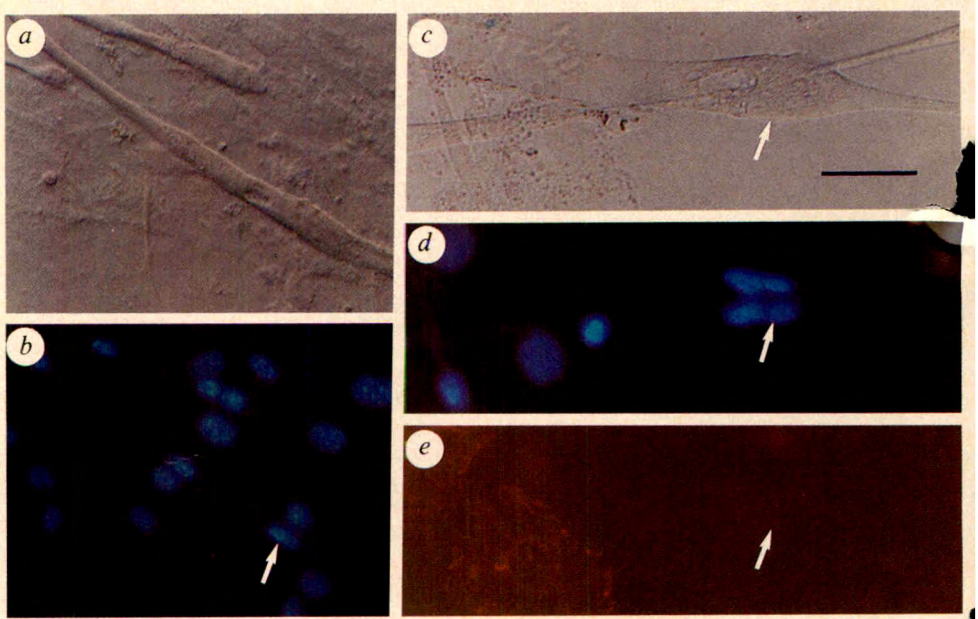

FIG. 2 Dysgenic myotubes rescued by co-culture with fibroblasts contain incorporated fibroblast nuclei. Rat2 cells were added to a dysgenic myoblast culture, and myotubes that exhibited spontaneous contractions were identified 8 days later and photographed using Hoffman differential contrast optics; two such rescued myotubes are shown (*a*, *c*). The same myotubes, viewed under ultraviolet fluorescence after staining with Hoechst 33342, are illustrated in *b* and *d*, respectively. Each contained an incorporated rat nucleus (indicated by an arrow), which is distinguishable by its homogeneously stained chromatin. Mouse nuclei display a punctate chromatin staining. In *e*, the same myotube as in *c* and *d* is shown after immunostaining for rat Thy-1.1 antigen. Note that the two rat fibroblasts (that align with the two large homogeneously stained nuclei in the left-hand portion of *d*), display red labelling for the presence of Thy-1.1 in their plasma membranes. By contrast, the rat nucleus indicated by the arrow is not surrounded by red staining, indicating that this nucleus is incorporated into the myotube and is no longer part of a fibroblast. Scale bar, 50 μm for all parts of figure.

METHODS. Rat2 fibroblasts (obtained from American Type Culture Collection) were added to cultures of dysgenic myoblasts as described in Fig. 1 legend. Myotubes that twitched spontaneously were identified by marks on the lower surface of the culture dish. Living cultures were stained with Hoechst 33342 at 3 μg ml^{-1} for 10 min at 37 °C in culture medium. For immunocytochemical staining, cultures were incubated at 37 °C for 10 min with a mouse monoclonal antibody against rat Thy-1.1 antigen (Chemicon, diluted 100-fold in culture medium). After washing, a tetramethylrhodamine isothiocyanate-conjugated goat anti-mouse IgG (Sigma, diluted 50-fold in culture medium) was applied for 10 min at 37 °C. After several washes to remove unbound antibody, cultures were fixed in 4% paraformaldehyde in phosphate-buffered saline.

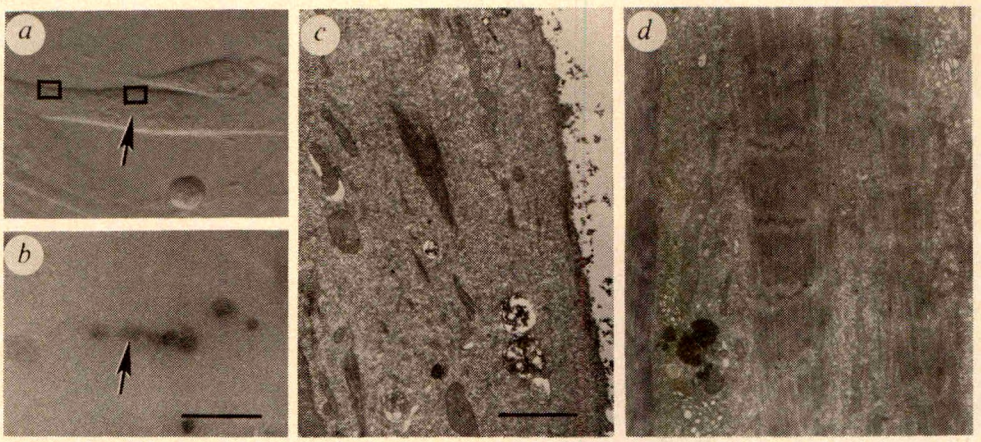

FIG. 3 Ultrastructural restoration only occurs near the normal nucleus within a rescued dysgenic myotube. A dysgenic myotube, rescued by the addition of rat NRK-52E fibroblasts, was viewed by Hoffman differential contrast optics (*a*) and by ultraviolet fluorescence after staining with Hoechst 33342 (*b*). The rescued myotube contains a single rat nucleus (indicated by the arrow). Electron micrographs of the regions distant from the rat nucleus show disorganized myofilaments (*c*) typical of non-rescued dysgenic myotubes, whereas those of the region near the rescuing rat nucleus show sarcomeric organization of the contractile proteins (*d*). The regions illustrated in *c* and *d* correspond to those in the left and right boxes in *a*, respectively. Scale bars, either 50 μm (a, b) or 2 μm (*c*, *d*).
METHODS. NRK-52E fibroblasts were added to a dysgenic myoblast culture. After 9 days, a myotube that twitched spontaneously was identified, stained with Hoechst 33342 and photographed. The culture was then fixed in 2.5% glutaraldehyde, 0.5% tannic acid in 0.1 M phosphate buffer, pH 7.4. The culture was post-fixed in 2% osmium, stained with uranyl acetate and embedded in plastic. Thin sections were post-stained with uranyl acetate and Sato's lead stain[18], and were viewed with an electron microscope (JEOL 1200EX).

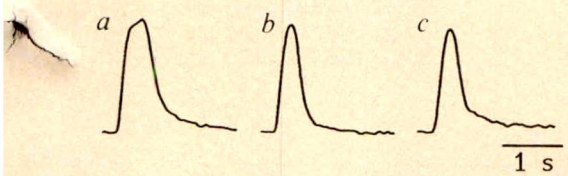

FIG. 4 Calcium entry is not required for electrically evoked contractions of dysgenic myotubes rescued by fibroblasts. Contractions were elicited with the rescued myotube bathed in normal physiological saline (*a*), in Ca^{2+}-free saline (*b*) and after return to normal saline (*c*). Tetrodotoxin (3 μM) was present to block spontaneous contractions. The normal saline[17] contained 2 mM Ca^{2+} and 1 mM Mg; the Ca^{2+}-free saline contained 3 mM Mg^{2+}. Electrical stimulation and optical recording of contractions were as described previously[4]. Rescue of this dysgenic myotube was effected by addition of Rat2 fibroblasts.

dihydropyridine-sensitive Ca^{2+} currents in dysgenic myotubes that have been rescued by fibroblasts[6], this indicates that a normal gene for the skeletal muscle dihydropyridine receptor is expressed in these myotubes. Because the genome of dysgenic mice lacks a functional copy of the normal gene for the dihydropyridine receptor[4], we presume that muscle cytoplasm induces the fibroblast nucleus to express muscle-specific genes, as has been demonstrated through artificially induced fusion[7].

We have shown here that in tissue culture, fibroblasts are able to fuse with developing myotubes. Fibroblasts seem to fuse very rarely or not at all if they are added after myotubes have fully formed. We do not yet know whether a similar fusion process also can occur *in vivo* or, conversely, whether mechanisms exist to prevent such fusions. If fibroblasts can fuse with developing muscle *in vivo*, they might serve as a useful donor cell-type for the treatment of genetic diseases of muscle in humans[14–16]. □

HUMAN cluster-of-differentiation 1 (CD1) is a family of cell surface glycoproteins of unknown function expressed on immature thymocytes, epidermal Langerhans cells and a subset of B lymphocytes[1–3]. Three homologous proteins, CD1a, b and c, have been defined serologically[4], and the CD1 gene locus on human chromosome 1 contains five potential CD1 genes[5]. Analysis of the predicted amino-acid sequences of CD1 molecules reveals a low but significant level of homology to major histocompatibility complex (MHC) class I and class II molecules[5,6], and, like MHC class I molecules, CD1 molecules are associated non-covalently with β_2-microglobulin[7]. These structural similarities to known antigen-presenting molecules, together with the expression of CD1 on cells capable of antigen presentation, suggest a role for CD1 molecules in antigen recognition by T cells. Here we demonstrate the specific recognition of CD1a by a $CD4^-CD8^-$ $\alpha\beta$ T-cell receptor (TCR) expressing cytolytic T lymphocyte (CTL) line and the specific

recognition of CD1c by a $CD4^-CD8^-$ $\gamma\delta$TCR CTL line. The interaction of CD1-specific CTLs with $CD1^+$ target cells appeared to involve the CD3–TCR complex, and did not show evidence of MHC restriction. These results suggest that for a subset of T cells, CD1 molecules serve a function analogous to that of MHC class I and II molecules.

We have previously described a $CD4^-CD8^-$ $\gamma\delta$TCR CTL line, IDP2, which showed specific MHC-independent lysis of the MOLT-4 thymic leukaemia-cell line[8]. By screening another 21 randomly derived $CD4^-CD8^-$ peripheral-blood T-cell lines (13 expressing $\gamma\delta$TCR, 8 expressing $\alpha\beta$TCR), we found one other CTL, BK6 ($\alpha\beta$TCR), with a similar pattern of target recognition. As MOLT-4 expresses CD1a, b and c, we considered that one of these could be the specific target structure recognized by these CTL and examined this by testing the ability of anti-CD1a, b or c monoclonal antibodies to block lysis. As seen in Fig. 1, lysis of MOLT-4 by BK6 was inhibited by the three anti-CD1a monoclonal antibodies tested, but not by those specific for CD1b or CD1c. Conversely, lysis by IDP2 was inhibited by the four anti-CD1c monoclonal antibodies tested, but not by those specific for CD1a or CD1b (Fig. 1). Anti-MHC antibodies specific for either monomorphic determinants of class I (W6/32 and BB7.7, Fig. 1) or class II (LB3.1, data not shown) had no effect on the lysis of MOLT-4 cells by either cell line. Anti-CD8 monoclonal antibody OKT8, which does not bind detectably to either CTL, also had no effect (Fig. 1).

Similar blocking experiments were carried out with monoclonal antibodies directed against components of the CD3-associated TCR complex (Fig. 2). Anti-CD3 antibodies (SPV-T3b) inhibited target-cell lysis by both T-cell clones, supporting a role for the CD3–TCR complex in CD1 recognition. The effects of antibodies against other parts of the CD3–TCR complex supported this idea, as the lysis of MOLT-4 by BK6 was inhibited by an antibody (BMA031) that binds specifically to the $\alpha\beta$ TCR complex, whereas lysis by IDP2 was inhibited by antibodies that bind to the δTCR (anti-TCRδ1) or γTCR (anti-TiγA; ref. 9) chains.

To demonstrate directly that CTLs BK6 and IDP2 recognized CD1a and CD1c respectively, we generated a series of CD1 transfectant cell lines. Transfectants of murine T–T hybridoma BY155.16 (ref. 10) and murine L-cell fibroblasts expressing CD1a or CD1c were used as targets. As predicted from the monoclonal antibody blocking data, a CD1a transfectant of BY155.16 was lysed by BK6, whereas a CD1c transfectant was not (Fig. 3*a*, left). Conversely, IDP2 lysed the CD1c transfectant but not the CD1a transfectant (Fig. 3*a*, right). Similar results were obtained using L cells transfected with CD1a and CD1c as targets (Fig. 3*b*). In all cases, monoclonal antibodies specific for the appropriate form of CD1 blocked specific lysis of the CD1 transfectants (Fig. 3*a–c*). Recognition of the appropriate form of CD1, therefore, could be demonstrated for each clone, regardless of the cell type into which CD1 was introduced.

Lysis of murine transfectants was relatively inefficient, requiring high effector-to-target-cell ratios to achieve significant levels (Fig. 3*a*, *b*). Such inefficiency may have been due to the absence from murine cells of ligands (for example, ICAM-1 (intracellular adhesion molecule-1) and LFA-3 (lymphocyte-function associated antigen-3) for human T-cell accessory molecules important in CTL-target interactions[11]. This possibility was supported by results obtained with CD1 transfectants of the human rhabdomyosarcoma-cell line RD (ref. 12). BK6 lysed a $CD1a^+$ transfectant of the human cell line much more efficiently than the corresponding $CD1a^+$ murine transfectants (Fig. 3*c*), despite a lower level of CD1a expression on the human cells (data not shown). Lysis of the $CD1a^+$ RD transfectant by BK6 was specific for CD1a, as it was blocked by anti-CD1a monoclonal antibody and no lysis of a $CD1b^+$ RD transfectant was observed (Fig. 3*c*).

Lysis of $CD1^+$ targets by CTLs BK6 and IDP2 implied that the CD1-dependent interaction between effector and target cells resulted in activation of the CTLs. To confirm this by an independent approach, we examined the production of interleukin-2 (IL-2) by BK6 after incubation with $CD1a^+$ target cells. Culturing BK6 in the presence of the $CD1a^+$ RD transfectant cells caused measurable IL-2 secretion, which was not seen if BK6 was cultured under the same conditions with the $CD1b^+$ transfectant (Fig. 4). The IL-2 secretion stimulated by CD1a recognition was completely inhibited by a monoclonal antibody specific for CD1a, whereas IL-2 secretion stimulated by phytohaemagglutinin was not affected by the addition of this anti-CD1a antibody (Fig. 4).

Our results show that some peripheral T cells can recognize CD1 molecules, and that this recognition triggers cellular events

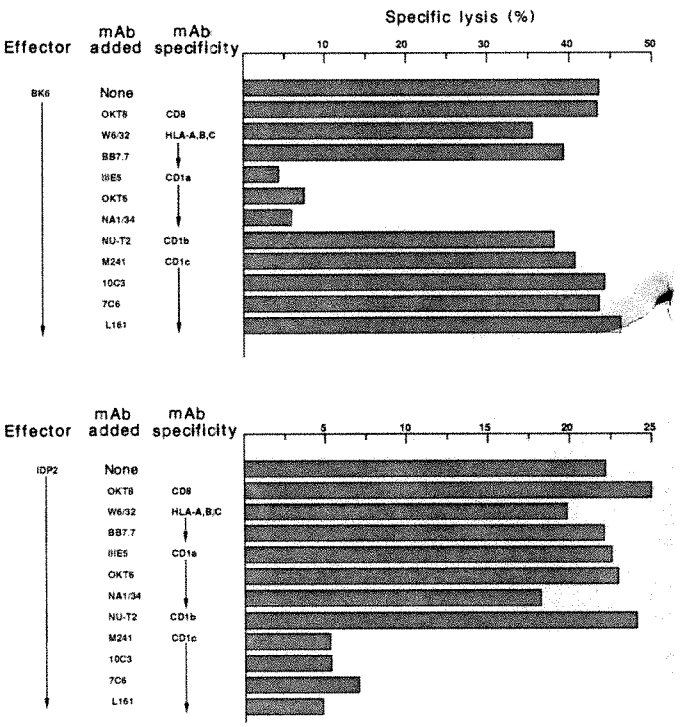

FIG. 1 Anti-CD1 monoclonal antibodies (mAb) block lysis of MOLT-4 cells by CTLs BK6 and IDP2. MOLT-4 T-leukaemia cell line is $CD1abc^+$, MHC class I^+/II^-, $CD3^-CD4^+CD8^+$. Lysis by $\alpha\beta$TCR CTL BK6 (effector : target [E:T] ratio 20:1, top panel) was inhibited only by anti-CD1a antibodies (IIIE5 (ref. 20), OKT6 (ref. 21) and NA1/34 (ref. 1)). Lysis by $\gamma\delta$TCR CTL IDP2 (E:T ratio 10:1, bottom panel) was inhibited only by anti-CD1c antibodies (M241 (ref. 22), 10C3 (ref. 23), 7C6 (ref. 23) and L161 (ref. 4). Anti-MHC class I antibodies W6/32 (ref. 24) and BB7.7 (ref. 24), anti-CD1b antibody NU-T2 (ref. 4) and anti-CD8 antibody OKT8 (ref. 21) did not inhibit lysis. Results are means of triplicate values with standard errors of less than 8%, and are representative of three separate experiments.

METHODS. Assay of chromium release and calculation of per cent specific lysis have been described[8]. ^{51}Cr-labelled MOLT-4 target cells were incubated with the indicated monoclonal antibody (10^{-3} dilution of ascites fluid) for 30 min at room temperature before addition of CTLs. All antibodies bound to saturation under these conditions. The derivation and characterization of the IDP2 line have been described[8]. CTL line BK6 was derived from the peripheral blood of a patient with systemic lupus erythematosus. Briefly, mononuclear cells recovered after treatment with anti-CD4 and -CD8 monoclonal antibodies and rabbit complement (Cedar Lane) were expanded for two weeks in IL-2-containing medium[8] with anti-CD3 antibody SPV-T3b (ref. 25) ascites at a 10^{-4} dilution as a polyclonal T-cell mitogen. Cells were then stained with a mixture of monoclonal antibodies OKT4 (ref. 21) (anti-CD4), OKT8 and anti-TCRδ1 (ref. 26), and unstained cells isolated by sorting with an Epics IV FACS (Coulter Electronics). BK6 was obtained by seeding these cells at limiting dilution (2.5 cells per well, plating efficiency 5%). This cell line has been in continuous culture for one year, and maintains the stable phenotype $\alpha\beta$TCR $CD4^-CD8^-$ based on staining with monoclonal antibodies BMA031 (ref. 27) (anti-$\alpha\beta$TCR), OKT4 and OKT8. Both IDP2 and BK6 were negative for cell-surface expression of CD1a, b and c as judged by staining with specific antibodies.

similar to those seen when T cells interact with antigens presented by self-MHC molecules. The two CTLs studied were each specific for a single form of CD1, either CD1a or CD1c. This specificity, together with the blocking by monoclonal antibodies against components of the CD3-TCR complex, indicates that the recognition is mediated by the specific antigen receptors of these CTLs. It is unlikely that this recognition of CD1 involves classical MHC molecules, at it occurred when the appropriate form of CD1 was expressed on a variety of MHC-unrelated target cells of human or murine origin, and could not be blocked by antibodies specific for monomorphic determinants of MHC molecules. Nevertheless, we cannot exclude the possibility of co-recognition of a non-polymorphic MHC determinant not susceptible to blocking by the monoclonal antibodies used. Evidence to date indicates that CD1 molecules isolated from different individuals do not show significant polymorphism[13,14], so the recognition we have observed is not likely to be analogous to the frequent alloreactivity shown by T cells towards polymorphic MHC determinants. The alternative possibilities that these CD1-specific CTLs are autoreactive to unmodified self-CD1 molecules, or are recognizing an antigen produced by the target cells and presented by CD1, cannot yet be resolved.

The frequency with which peripheral T cells show CD1 reactivity has not yet been studied in detail. The finding of two examples, however, in our panel of 22 $CD4^-CD8^-$ T-cell lines derived without intentional selection for CD1 recognition, indicates that this may be a relatively common reactivity, at least within this phenotypic subset. In addition, we have recently isolated and partially characterized $CD4^-CD8^-$ T-cell lines derived from synovial tissue of rheumatoid arthritis patients. These T-cell lines are 80–90% $\gamma\delta$TCR positive and show specific cytotoxicity of $CD1c^+$-transfected target cells (S.P. and M.B.B., unpublished data). The isolation of such cells from inflamed synovium and of the CD1a-reactive CTL BK6 from the blood of a systemic lupus erythematosus patient raises the possibility of a role for CD1-reactive $CD4^-CD8^-$ T cells in autoimmune diseases. In this regard, it is of interest that $CD4^-CD8^-$ $\alpha\beta$TCR-expressing T cells have recently been shown to be expanded in the blood of humans with systemic lupus erythematosus (ref. 15; S.P. and M.B.B., unpublished observation), as they are in the peripheral lymphoid organs of mice with hereditary autoimmune diseases that have features similar to human systemic lupus erythematosus (ref. 16). Any conclusions concerning the pathogenetic significance of CD1-reactive T cells, however, must be considered tentative, as other studies indicate that reactivity against $CD1a^+$- and $CD1c^+$-transfected target cells is also detectable in the $CD4^-CD8^-$ fraction of normal human peripheral blood (P.A.B. and C.T., unpublished results).

Previously we[17], and others[18,19], have proposed that relatively non-polymorphic MHC class I-like molecules may serve as ligands for the CD3-associated TCRs of $\gamma\delta$TCR-positive cells. Such a role has already been suggested for antigens encoded in the Tl region of the MHC, which appear to be recognized by a limited number of murine $\gamma\delta$TCR T-cell lines[18]. Our results indicate that CD1 molecules may also serve as specific ligands not only for some human $\gamma\delta$TCR positive cells, which are a majority of the circulating $CD4^-CD8^-$ T cells, but also for some $CD4^-CD8^-$ $\alpha\beta$TCR cells, which have been reported recently to be a distinct subset of circulating T cells in normal human peripheral blood[15]. Although we have not demonstrated directly the presentation of a foreign antigen by CD1, our results, together with the known structure and tissue distribution of

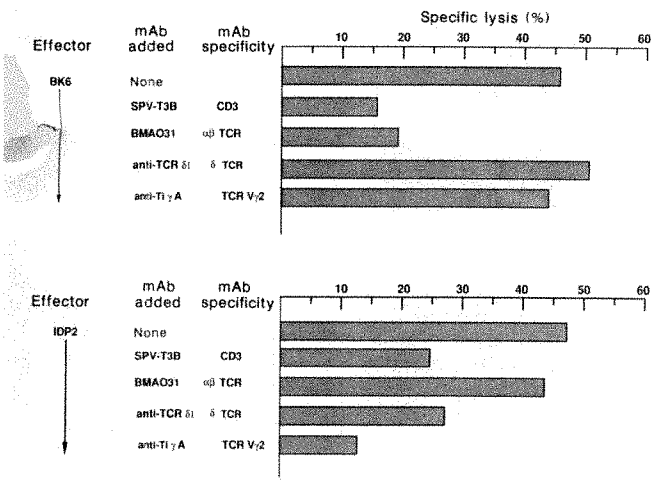

FIG. 2 Anti-TCR monoclonal antibodies block CD1-specific lysis. Lysis of MOLT-4 by CTL lines BK6 (E:T ratio 25:1) and IDP2 (E:T ratio 50:1) in the presence or absence of the indicated antibodies (mAb) was determined by ^{51}Cr release. Results shown are representative of three separate experiments, and are means of triplicate values with standard deviations less than 10%.

METHODS. CTLs and target cells were incubated together with antibodies for 30 min at room temperature before carrying out assay of ^{51}Cr release. BMA031 was added as purified antibody at a final concentration of 10 $\mu g\ ml^{-1}$. Other antibodies were used as ascites fluid at a final dilution of 10^{-3}.

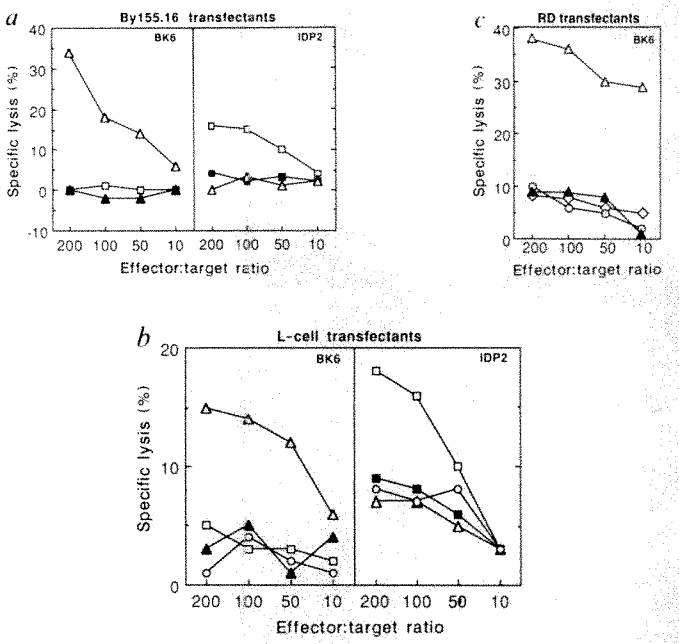

FIG. 3 CD1-specific CTLs lyse target cells transfected with the appropriate form of CD1. *a*, Lysis of BY155.16 cells transfected with CD1a or CD1c; *b*, Lysis of untransfected L cells or of L cells transfected with CD1a or CD1c; *c*, Lysis of untransfected RD cells or of RD cells transfected with CD1a or CD1b. Target cells indicated by symbols as follows: $CD1a^+$ transfectants (△), $CD1c^+$ transfectants (□), $CD1a^+$ transfectants preincubated with IIIE5 (anti-CD1a) antibody (▲), $CD1c^+$ transfectants preincubated with M241 (anti-CD1c) antibody (■), untransfected target cells (○, *b* and *c* only), $CD1b^+$ transfectant (◇, *c* only).

METHODS. Full-length cDNA clones for CD1a, b and c[28] were directionally cloned into the *Xho*I-*Bam*HI sites of the expression vector pSRα-NEO (ref. 29) using standard techniques[30]. CD1-pSRα-NEO constructs were introduced into BY155.16 cells by electroporation[31], and into RD and L cells by calcium phosphate mediated transfer[32]. Cells resistant to G418 (Gibco; 2 $mg\ ml^{-1}$ for BY155.16, 1 $mg\ ml^{-1}$ for L cells, and 0.5 $mg\ ml^{-1}$ for RD cells) were subcloned at limiting dilution. Subclones expressing CD1a, b or c were identified by surface staining with appropriate monoclonal antibodies. ^{51}Cr-release assay and monoclonal antibody blocking were carried out as described in legend to Fig. 1.

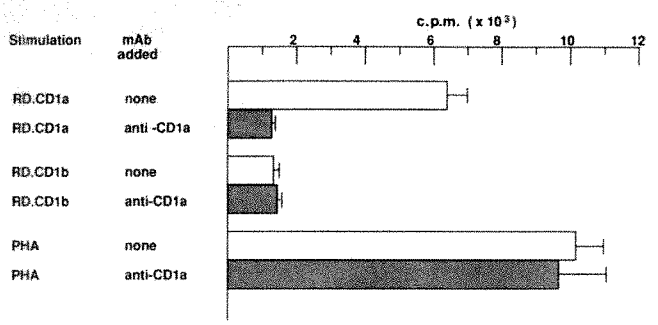

FIG. 4 Recognition of CD1a stimulates IL-2 production by CTL BK6. Culture supernatants of BK6 stimulated with CD1 transfectants of RD cells or with phytohaemagglutinin (PHA) in the presence or absence of anti-CD1a monoclonal antibody (mAb) were tested for IL-2 activity using IL-2-dependent cell line CTLL20. Results expressed as c.p.m. of [^{3}H]thymidine incorporation by CTTL20 cells.
METHODS. BK6 cells (2.5×10^4) were cultured for 24 h in 96-well flat bottom microtitre plates (Flow Laboratories) with 10^4 RD.CD1a (CD1a$^+$) or RD.CD1b (CD1b$^+$) or with PHA (Gibco, 1:1,000 dilution) in 0.2 ml culture medium (RPMI-1640, 10% human serum, 2 mM L-glutamine, 1 mM HEPES, 1% penicillin-streptomycin) containing 1 ng ml^{-1} phorbol myristate acetate (PMA) (Sigma). IIIE5 (anti-CD1a) ascites fluid was added to a final dilution of 10^{-3}. IL-2 was assayed by a modification of a published method[33], using 4,000 CTLL20 cells and a 1:2 dilution of supernatant. Results are means ±1 s.e.m. of triplicate cultures, and are representative of three separate experiments. [^{3}H]thymidine incorporation by CTLL20 in the absence of IL-2 for the experiment shown was 1,158 ± 115 c.p.m. Similar results were obtained in the absence of PMA, although the magnitude of response was lower (data not shown).

these molecules, give rise to the hypothesis that some T cells recognize antigens presented by CD1 molecules. □

ACKNOWLEDGEMENTS. We thank Drs A. Arruffo and B. Seed for the CD1a, b and c cDNA clones, Dr Ken-ichi Arai for the pSRα-NEO vector, Dr P. H. Schur for specimens of human peripheral blood, Dr H. Band for reviewing this manuscript, and, for their gifts of monoclonal antibodies, Drs W. Knapp (10C3 and 7C6), M. Amiot and L. Boumsell (L161), R. Knowles (M241), B. Seed (NU-T2), R. Kurrle (BMA031), T. Hercend (anti-TiγA), and J. De Vries (SPV-T3b). Technical assistance was provided by A. Reinach and S. Piscarzyk. This work was supported by the NIH and ACS.

Voltage-dependent anion channels in the plasma membrane of guard cells

Bernhard U. Keller*†, Rainer Hedrich* & Klaus Raschke*

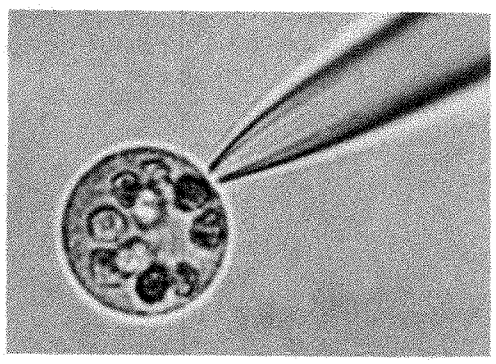
WHEN plants assimilate CO_2 from the atmosphere, water vapour escapes. This exchange of gases can be moderated by the plant through volume changes of guard cells, which in pairs surround each stomatal pore in the epidermis and act as turgor-operated valves. When light intensity diminishes or water stress develops, guard cells shrink and stomata close. This process requires the release of ions from the guard cells. Voltage-dependent K^+ channels[1,2] provide a path for cations. The required corresponding passage for anions, particularly chloride and malate[3], is not known at the molecular level. We have applied the patch-clamp technique[4] to guard-cell protoplasts of *Vicia faba* and found strongly voltage-dependent activities of single anion channels in the plasma membrane (plasmalemma). These channels have a conductance of 39 pS in 100 mM KCl and are permeable for chloride and malate. They become active at membrane potentials positive to −80 mV. Their maximum activity occurs at −40 mV. The resulting outward Cl^- currents of individual guard cells are at least 25 pA. These voltage-dependent anion channels provide a mechanism for the control of salt efflux from guard cells.

Patch-clamp experiments were performed on guard-cell protoplasts isolated from *Vicia faba* by a gentle procedure (no agitation) at the temperature of plant cultivation[5]. High-resistance membrane seals[4] were formed between the patch pipette and the plasma membrane (Fig. 1). Fluxes of K^+, Cl^- and malate^{2-} were recorded at the cellular and single-channel level using the whole-cell configuration as well as isolated membrane patches[4].

Whole-cell currents were measured in the presence of 150 mM KCl in the pipette and 30 mM KCl in the bath (Fig. 2*a*, filled circles). The membrane conductance was studied as a function of the membrane voltage applied to the cytoplasmic side of the plasma membrane. The relationship between current and voltage depended on the voltage range considered. At membrane potentials below −100 mV, large inward currents occurred. They were identified as inward K^+ currents by reversal potential analysis[2]. Membrane potentials above −20 mV, particularly positive potentials, caused outward K^+ currents; at +50 mV they were as large as 100 pA. In the voltage range between −100 mV and −80 mV, which corresponds to the resting potentials of guard cells[6], the current was close to zero and the resistance of the plasma membrane was larger than 10 GΩ. Increasing the potential to values positive to −80 mV led to an inward current with a maximum conductance at −40 mV, the reversal potential for K^+.

To test whether this current was carried by anions, K^+ was replaced by Cs^+ or *N*-methylglucamine (NMG), which are known to permeate K^+ channels at negligible rates[7] (Fig. 2*a*, open circles). Below −100 mV and above −20 mV, currents were much smaller than they were in the presence of K^+, or even zero. Their fluctuations reached a maximum amplitude at −41 mV (Fig. 2*b*) and they disappeared at +39 mV (Fig. 2*b*), close to the Nernst potential for Cl^- (+40 mV). These results provide evidence that anions are the main charge carrier[5] of the whole-cell currents in the presence of CsCl solutions. At −81 mV, the opening and closing of single anion channels could be clearly discerned, even in whole-cell recordings.



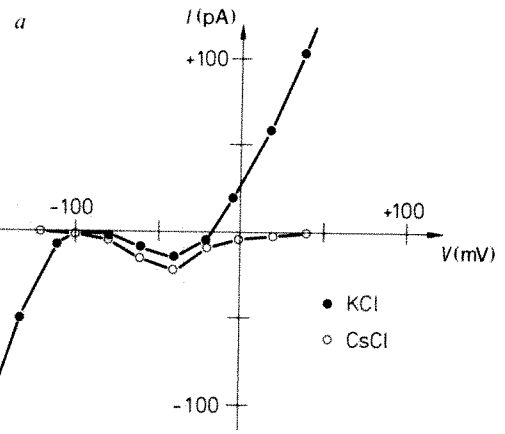


FIG. 1 Micrograph (Nomarski interference contrast) of a guard-cell protoplast from *Vicia faba*.
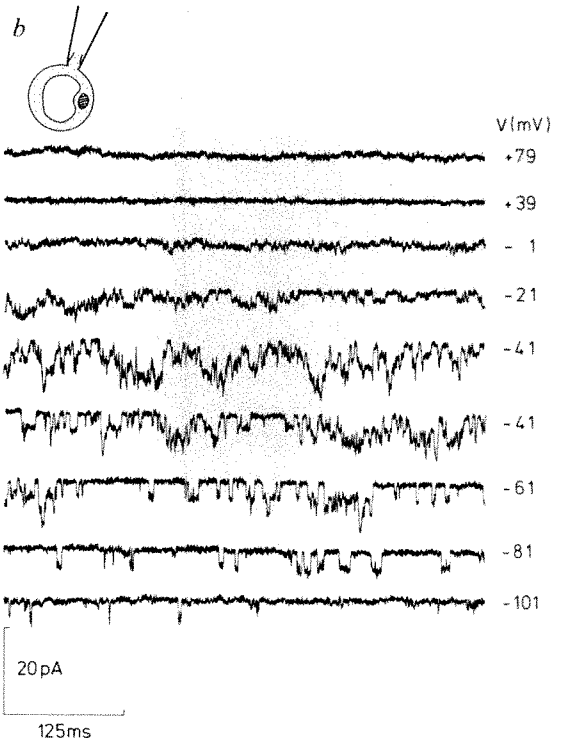
METHODS. Guard-cell protoplasts were isolated without agitation by overnight incubation at 20 °C in small Petri dishes containing 2.5 ml of 400 mM D-mannitol, 10 mM Na-ascorbate, 1 mM $CaCl_2$, 2% (w/v) cellulase (Onozuka RS), 1% pectinase (for example, Mazerozyme), 0.5% BSA, 0.05% kanamycin sulphate, pH 5.5, with osmolality adjusted to produce incipient plasmolysis of guard cells. Protoplasts were purified by filtration and centrifugation[5].

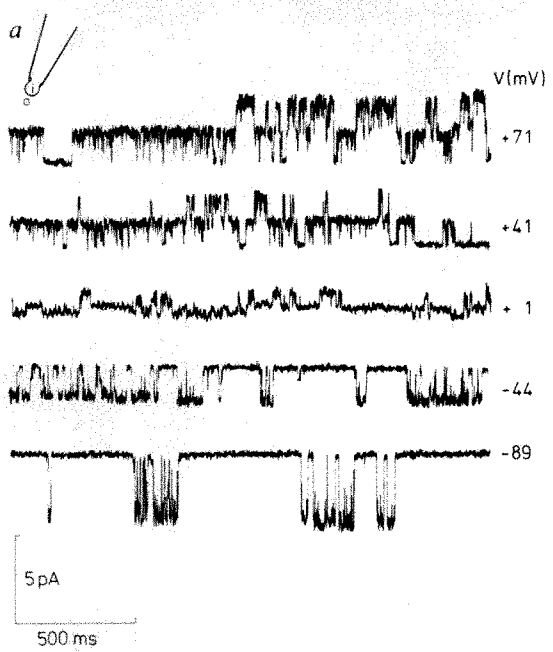
In inflated guard cells, malate is the major anion. Replacing chloride by malate left the voltage dependence of the anion current essentially unchanged. The maximum current still occurred close to −40 mV, but was reduced to values below 10 pA. After raising concentrations of cytosolic free Ca^{2+} to >5 μM, anion currents could be measured at voltages negative to −60 mV. At a Ca^{2+} concentration in the pipette of >2 mM, whole-cell anion currents did not exceed 30 pA in the presence of CsCl solutions.

After withdrawal of the pipette from the membrane surface, single anion channels and K^+ channels were recorded in the outside-out patch configuration in K^+ salt solutions (Fig. 3). To avoid interferences by the activity of K^+ channels, we limited the investigation to voltages positive to −90 mV, at which inward K^+ channels were closed. Between −90 mV and −40 mV, the membrane current was dominated by the opening of single anion channels. Downward current deflections represented single-channel currents of 3.9 pA at −90 mV. In excised patches, anion channels were most active when the concentration of free Ca^{2+} on the cytoplasmic side of the membrane was raised to 3–5 μM. Channel activity occurred in bursts separated by silent periods of 0.2 to 0.9 s duration. At voltages positive to −20 mV, the opening of outward K^+ channels appeared as upward current deflections. Multiple current levels indicated the simultaneous opening of several K^+ channels in the patch. At voltages above +20 mV, currents through the plasma membrane were dominated by the activity of K^+ channels, with a current amplitude of 2 pA at +70 mV (Fig. 3*a*).

For single anion channels, a main conductance level of 39 pS in 100 mM KCl was calculated from current–voltage measurements (Fig. 3*b*). Occasionally, channel openings at lower conductance levels could be observed, as shown in Fig. 3*c*. To assess the selectivity of the anion channels, Cl^- was replaced by several other anions. In reversal-potential measurements we found a permeability sequence of $NO_3^- > Cl^- > malate^{2-}$. Anion permeation was blocked by the addition of 10 μM Zn^{2+}, a well-known blocker of anion channels[8] (Fig. 4).

The anion currents we observed differ significantly from the anion currents recently described in the plasma membrane of plant cells. Anion currents in suspension-cultured cells of *Asclepias tuberosum* were elicited by hyperpolarizing instead of depolarizing voltages and had a magnitude of 300–400 pA in the whole-cell configuration[9]. The corresponding single-channel conductance was 100 pS compared with 39 pS for guard cells,





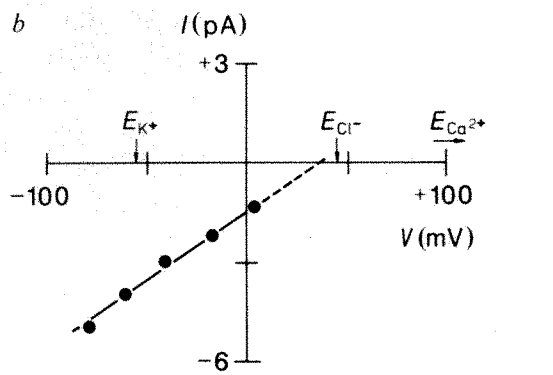


FIG. 2 Whole-cell currents of guard-cell protoplasts. *a*, ●, current–voltage (*I–V*) relationship of protoplasts bathed in 30 mM KCl, 1 mM $CaCl_2$, 2 mM $MgCl_2$, 10 mM HEPES–Tris buffer, pH 5.5. Pipette solution, 150 mM KCl, 2 mM $MgCl_2$, 2 mM Mg ATP, 1 mM EGTA, 10 mM HEPES–Tris buffer, pH 7.2. Current–voltage relationships were determined by continuously increasing the voltage from −150 mV to +50 mV. Voltage and current were plotted on an *x–y* screen and corrected for the (ohmic) resistance of the membrane seal. Downward currents corresponded to cation influx into (or anion efflux from) the protoplast or both. ○, current–voltage relationship of protoplasts bathed in 30 mM CsCl, 1 mM $CaCl_2$, 2 mM Mg $MgCl_2$, 10 mM HEPES–Tris buffer, pH 5.6. Pipette solution was 150 mM CsCl, 2 mM $MgCl_2$, 2 mM Mg-ATP, 1 mM EGTA, 10 mM HEPES–Tris buffer, pH 7.2. *b*, Whole-cell currents recorded at various voltages *V* in asymmetrical CsCl solutions corresponding to those in Fig. 2*a* (○). Membrane potentials were controlled by an EPC-7 patch-clamp amplifier (List Electronics, Darmstadt), and data were stored in digital form on a video-tape recorder. Off-line analysis was performed on a PDP-11/73 computer after filtering the data at 2 kHz (8-pole Bessel filter). All membrane potentials refer to the cytoplasmic side of the plasma membrane. Experiments were performed at room temperature (20 ± 2 °C).

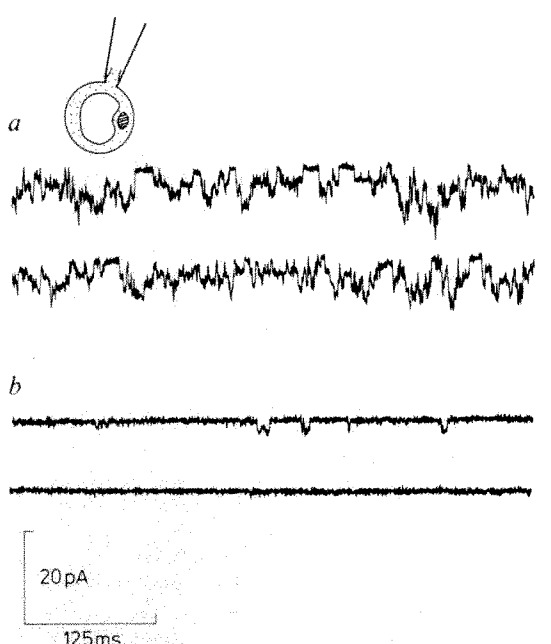

FIG. 4 Block of anion channels by extracellular Zn^{2+}. *a*, Currents through several anion channels were recorded in the whole-cell configuration. Protoplasts were bathed in 30 mM CsCl, 1 mM $CaCl_2$, 2 mM $MgCl_2$, 10 mM HEPES–Tris buffer, pH 5.6. Pipette solution, 150 mM CsCl, 2 mM $MgCl_2$, 2 mM MgATP, 1 mM EGTA, 10 mM HEPES–Tris buffer, pH 7.2. The membrane potential was held at −41 mV. *b*, Addition of 10 μM $ZnCl_2$ to the bath solution blocked the activity of anion channels.

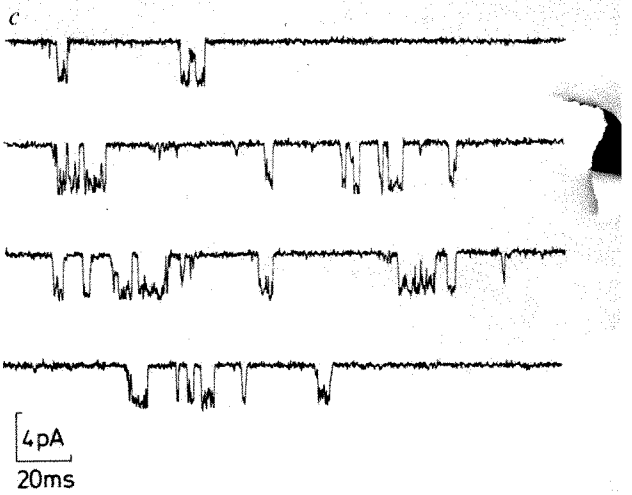

FIG. 3 Single-channel recordings from excised patches. *a*, Single K^+- and anion-selective channels measured in outside-out patches in an asymmetrical solution of KCl. Pipette solution, 100 mM KCl, 2 mM $MgCl_2$, 2 mM Mg-ATP, 1 mM EGTA, 10 mM HEPES–Tris buffer, pH 7.2; Bath solution, 10 mM KCl, 1 mM $CaCl_2$, 2 mM $MgCl_2$, 10 mM HEPES–Tris buffer, pH 5.8. Upward current deflections at positive membrane voltages correspond to K^+ currents flowing through open K^+ channels. Current recordings at negative voltages are dominated by the opening and closing of single anion channels. Note the gating of both K^+- and anion channels at $V = +1$ mV. *b*, Single-channel current–voltage relationship. Single-channel current–voltage curve observed in a 10-fold gradient of KCl. Pipette solution, 100 mM KCl, 2 mM $MgCl_2$, 2 mM Mg-ATP, 0.1 mM $CaCl_2$, 1 mM EGTA, 10 mM HEPES–Tris buffer, pH 7.3; Bath solution, 10 mM KCl, 1 mM $CaCl_2$, 2 mM $MgCl_2$, 10 mM HEPES–Tris buffer. pH 5.5. The Nernst potentials for Cl^-, K^+ and Ca^{2+} were $E_{Cl} = -44.1$ mV, $E_{K^+} = -55.0$ mV and $E_{Ca^{2+}} > +100$ mV, respectively (values corrected for ionic activities). Slope conductance, 39 pS. *c*, Currents through single anion-channels. Single-channel currents were recorded at −82 mV in the presence of the non-permeating cation NMG. Pipette solution, 100 mM NMG-Cl, 2 mM $MgCl_2$, 2 mM Mg-ATP, 1 mM EGTA, 10 mM HEPES–Tris buffer, pH 7.4. Bath solution, 10 mM NMG-Cl, 1 mM $CaCl_2$, 2 mM $MgCl_2$, 10 mM HEPES–Tris buffer, pH 5.5. Note the occurrence of channel substates in the first record from top.

indicating a striking discrepancy between anion transport in non-differentiated suspension-cultured cells and guard-cell protoplasts from developed leaves.

Our results also disagree with those of Schroeder and Hagiwara[10], who showed instantaneously activated, almost voltage-insensitive anion conductances in guard-cell protoplasts from *Vicia faba*. These anion currents were observed at high concentrations of cytoplasmic Ca^{2+} and exceeded outward K^+ currents by a factor of three (0.7 nA at −70 mV). Outward anion currents of that magnitude did not occur in guard cells embedded in the epidermis, where anion release during stomatal closure was equivalent to 30–40 pA[11]. Therefore, the anion channels shown here provide suitable molecular pathways to determine the magnitude of anion release from guard cells. Whether Ca^{2+}-activated anion conductances function in addition or alternatively to the voltage-regulated anion channels described here needs to be investigated further.

An early proposal was that the release of salts by guard cells is determined primarily by the anion permeability of the plasma membrane and that an increase in this permeability was sufficient to initiate stomatal closure[3,12]. The anion channels that we have described here would allow the depolarization required for ion release from guard cells. The ensemble conductance of the anion channels permeable to Cl^- and malate^{2-} can account for the observed rates of anion loss during stomatal closure[11]. The anion channels in guard cells indeed seem to provide a mechanism for controlled salt release. We propose that this

type of anion channel also functions in other types of plant cells, where it may be involved in the release of salts for the purpose of osmoregulation and for the control of turgor or cell volume. □

Trans-dominant inactivation of HTLV-I and HIV-1 gene expression by mutation of the HTLV-I Rex transactivator

Laurence Rimsky, Madeleine Duc Dodon*, Eric P. Dixon & Warner C. Greene

THE *rex* gene of the type I human T-cell leukaemia virus (HTLV-I) encodes a phosphorylated nuclear protein of relative molecular mass 27,000 which is required for viral replication[1–3]. The Rex protein acts by promoting the cytoplasmic expression of the incompletely spliced viral messenger RNAs that encode the virion structural proteins[4,5]. To identify the biologically important peptide domains within Rex, we introduced a series of mutations throughout its sequence. Two distinct classes of mutations lacking Rex biological activity were identified. One class corresponds to *trans*-dominant repressors as they inhibit the function of the wild-type Rex protein. The second class of mutants, in contrast, are recessive negative, rather than dominant negative, as they are not appropriately targeted to the cell nucleus. These results indicate the presence of at least two functionally distinct domains within the Rex protein, one involved in protein localization and a second involved in effector function. The *trans*-dominant Rex mutants may represent a promising new class of anti-viral agents.

Oligonucleotide-directed mutagenesis was employed to alter the primary sequence of the *rex* gene at 18 discrete sites (Fig. 1*a*). The boxed amino acids were replaced with a dipeptide, aspartic acid–leucine, by insertion of an in-frame oligonucleotide duplex that contains a diagnostic *Bgl*II restriction site. Each of these Rex mutants were then inserted into the pBC12/CMV eucaryotic expression vector[6] and the mutations verified by DNA sequencing. For functional analysis, a Rex-responsive reporter plasmid, pgTAX-LTR, was prepared (Fig. 1*b*). The pgTAX-LTR vector contains the two protein-coding exons of the *tax* gene separated by the HTLV-I *env* gene and the complete HTLV-I 3′ long terminal repeat (LTR). Contained within this 3′ LTR is a *cis*-acting Rex response element (RexRE) which seems to correspond to a complex RNA stem–loop structure[5,7]. Either direct or indirect binding of Rex to this RexRE probably underlies its post-transcriptional mechanism of action. The pgTAX-LTR vector does not itself produce Rex, because of a mutation introduced at the Rex initiator codon. In the absence of Rex, pgTAX-LTR produces the Tax protein, reflecting the translation of the spliced HTLV-I mRNA species that lacks virtually all of the *env* sequences. When pgTAX-LTR is co-transfected with the *rex* expression plasmid, pREX, however, synthesis of the HTLV-I Env protein is activated. This protein (relative molecular mass 68,000 (68K)) is readily identified by immunoprecipitation with the anti-HTLV-I envelope monoclonal antibody, 0.5-alpha (ref. 8) (Fig. 2*a*; lane 1). In contrast, no HTLV-I Env protein is detected when pREX is replaced by either pREV (lane 2) or pCMV-IL-2 (lane 3), which encode the HIV-1 Rev protein and human interleukin-2 polypeptide respectively. Also, no Env protein is identified when cells are transfected with pREX in the absence of pgTAX-LTR (lane 4). HTLV-I Env expression by pgTAX-LTR, therefore, is specifically induced in the presence of the wild-type Rex protein.

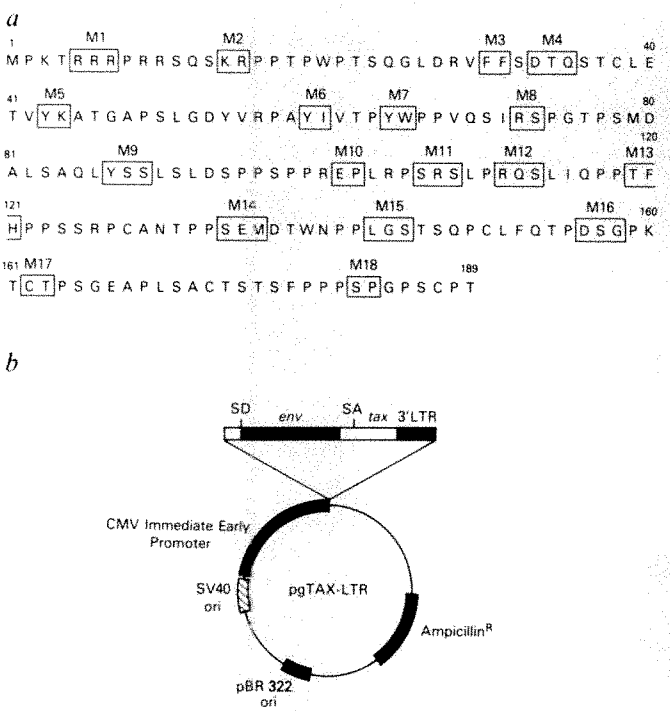

FIG. 1 *a*, Amino-acid sequence of the HTLV-I Rex protein and location of the 18 point mutations introduced. Using oligonucleotide-directed mutagenesis in the M13 bacteriophage[21], nucleotides encoding each of the boxed amino acids were removed and replaced in frame by an oligonucleotide encoding the aspartic acid–leucine dipeptide. Each mutant was subsequently inserted into the pBC12/CMV expression vector and the presence of the mutation confirmed by DNA sequencing of the double-stranded supercoiled templates. *b*, Structure of the Rex-responsive pgTAX-LTR expression vector. The 3′ end of the CR-1 HTLV-I provirus (a gift from Dr Flossie Wong-Staal) from the *Hin*dIII site at map position 5,013 (ref. 22) through to the 3′ LTR, was inserted into the pBC12/CMV expression vector. This fragment contains the two coding exons for Tax (white boxes), the complete *env* gene, and the entire 3′ LTR, including the Rex response element[5]. Although this vector contains the coding region for Rex, it does not synthesize this protein because of the introduction of a mutation at the *Sph*I site, which is coincident with the Rex translation initiation codon[14]. Expression of these HTLV-I sequences is promoted by the immediate early region of the human cytomegalovirus (CMV) and additional polyadenylation sequences provided by the 3′ region of the rat pre-proinsulin gene[6]. This vector produces Env only in the presence of Rex, but Tax is synthesized in the presence or absence of Rex.

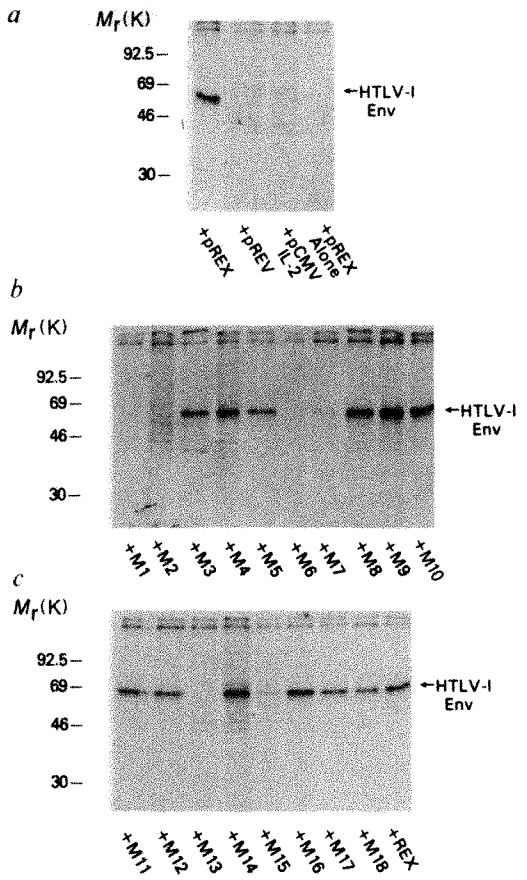

FIG. 2 *a*, Rex, but not Rev or IL-2, activates the expression of HTLV-I Env protein by the pgTAX-LTR vector. Subconfluent cultures of COS cells were co-transfected with pgTAX-LTR and pREX (ref. 14), pREV (ref. 15), or pCMV-IL-2 (ref. 6) using DEAE-dextran[23]. All plasmids were added at a concentration of 1.25 μg ml^{-1}. In the final lane, cells were transfected with pREX in the absence of pgTAX-LTR. Forty-eight hours after transfection, cells were metabolically labelled with [^{35}S] cysteine for 2 hours, subcellular extracts were fractionated. Samples were immunoprecipitated with 0.5-alpha human monoclonal antibody, which specifically reacts with the HTLV-I envelope protein[8]. Immunoprecipitates were analysed on SDS-10% polyacrylamide gels. The migration of molecular weight standards is indicated on the left. *b*, Analysis of biological activity of the *rex* mutants. After insertion into the pBC12/CMV expression vector, each of the *rex* mutants (designated M1–M18, see Fig. 1*a*) was co-transfected with pgTAX-LTR and the COS cell cultures were analysed for Rex-dependent HTLV-I Env protein expression as described above.

Each of the *rex* mutations was tested for biological activity by co-transfection with pgTAX-LTR vector. Twelve of these *rex* mutants displayed a wild-type phenotype. In contrast, five mutants (M1, M2, M6, M7 and M13) lacked apparent biological activity and one mutant (M15) was only partially functional (Fig. 2*b*). COS cells were next co-transfected with these six defective *rex* mutants and the pgTAX-LTR vector followed by the simultaneous analysis of HTLV-I Env, Tax and Rex protein expression (Fig. 3*a*–*c*). Although HTLV-I Env was only detected in the presence of the wild-type Rex protein (Fig. 3*a*; lane 7) or the partially active M15 mutant (Fig. 3*a*; lane 6), the 40K Tax protein was detected in all of the cultures (Fig. 3*b*). These findings indicate that the lack of *env* gene expression observed with the M1, M2, M6, M7 and M13 mutants is due to the specific loss of Rex biological activity, rather than to non-specific, toxic effects of these proteins in the transfected COS cell cultures. Each of the mutant Rex proteins was also directly identified by immunoprecipitation, indicating that each was expressed in a stable manner (Fig. 3*c*). The M2, M6, and M13 Rex mutants migrated in a manner indistinguishable from the wild-type Rex protein (Fig. 3*c*; lanes 2, 3, 5 and 7). Interestingly, the M7 and M15 proteins had a smaller apparent molecular weight (lanes 4 and 6), and the M1 mutant protein travelled as an electrophoretic doublet (lane 1). Sequencing of the entire protein-coding region in the M1, M7 and M15 mutants failed to reveal any changes other than the specific mutations introduced. These apparent differences in size, therefore, probably reflect altered post-translational processing of the mutant Rex proteins.

The *in situ* immunofluorescent staining of cells transfected with the wild-type *rex* or the biologically inactive M6, M7 and M13 Rex mutants revealed expression of these proteins in the nucleoli and nuclei of the transfected cells (Fig. 4). In sharp contrast, the M1 Rex mutant was detectable only in the cytoplasm, but the M2 Rex mutant was distributed homogeneously throughout the cell. In accordance with these results, the M1 and M2 mutations altered basic amino-acid residues located within a positively charged peptide domain that has been previously shown to function as a nucleolar localization signal[3]. Interestingly, the partially active M15 mutation led to a nuclear, but nucleolar-excluded, pattern of expression (Fig. 4). These findings raise the possibility that residues apart from the basic amino acids at the N-terminus may be involved in the nucleolar expression of Rex.

The Rex mutants were next tested for their capacity to block the biological action of the wild-type HTLV-I Rex and HIV

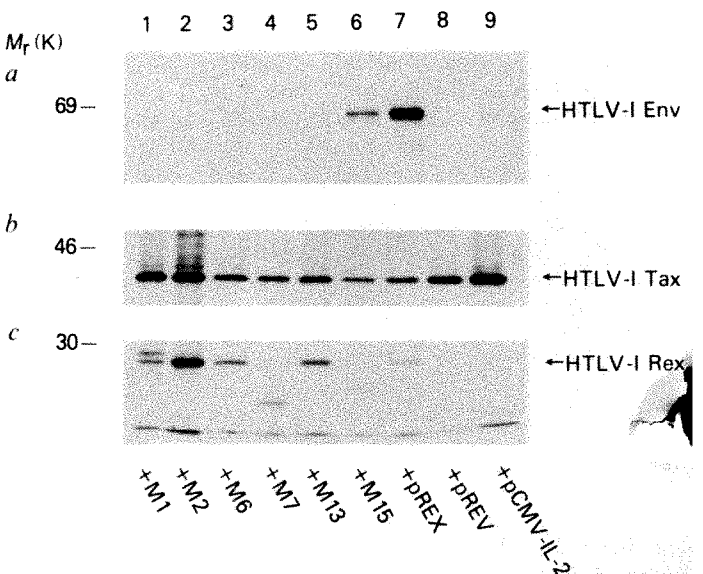

FIG. 3 Simultaneous analysis of HTLV-I Env, Tax, and Rex protein production in COS cells co-transfected with pgTAX-LTR (1.25 μg ml^{-1}) and the vectors encoding the biologically inactive (M1, M2, M6, M7, M13) or impaired (M15) mutant Rex proteins (1 μg ml^{-1}) or the wild-type pREX, pREV, and pCMV-IL-2 vectors (1 μg ml^{-1}). *a*, Analysis of HTLV-I Env production using the 0.5-alpha antibody for immunoprecipitation. *b*, Analysis of Tax protein production by pgTAX-LTR, which occurs in the absence or presence of Rex, using anti-Tax peptide specific antisera. *c*, Immunoprecipitation analysis of wild-type and mutant Rex protein production. In each case, the same radioactively labelled cellular extract was used for the three immunoprecipitations; only the relevant region of each of the resultant autoradiographs is presented. Immunoprecipitations were analysed on SDS-10% polyacrylamide gels.

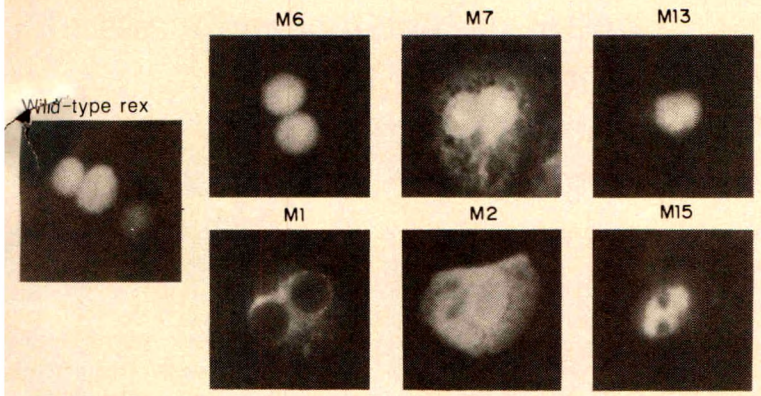

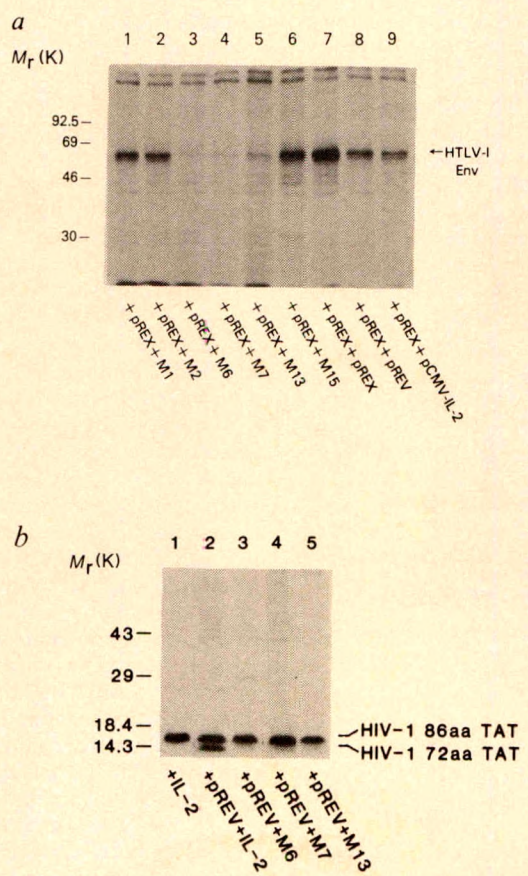

FIG. 4 Subcellular localization of the HTLV-I Rex mutants by immunofluorescence. COS cells were transfected with the expression plasmids indicated and fixed with paraformaldehyde 48 h later. The cells were then sequentially stained with rabbit anti-Rex peptide antiserum (1:100 dilution) and goat anti-rabbit IgG conjugated to rhodamine[23].

Rev proteins mediated through the RexRE and RevRE[9-13] (Fig. 5). When co-transfected with pgTAX-LTR and pREX in COS cells (panel *a*), a 10-fold molar excess of M6, M7 and M13 mutants displayed a dominant negative phenotype, as the action of the wild-type Rex protein was markedly inhibited (lanes 3–5). In contrast, the M1, M2 and M15 proteins functioned as recessive negative mutants, because the action of the wild-type Rex protein was not altered (lanes 1, 2 and 6). Similarly, the Rev protein of HIV-1 did not interfere with the action of the HTLV-I Rex protein (lane 8), nor did IL-2 (lane 9). We have previously shown that the HTLV-I Rex protein can functionally replace the HIV-1 Rev protein[14], so we next investigated whether *trans*-dominant Rex mutants could block the function of Rev in the HIV-1 system (Fib. 5*b*). As previously described, for cells transfected with the pgTAT vector[15], Rev induces the expression of a truncated (72 amino acids) rather than full-length (86 amino acids) form of the HIV-1 Tat protein (lane 2). When co-transfected with pgTAT and pREV (ref. 15) in COS cells, a 10-fold molar excess of M6, M7 or M13 Rex mutants inhibited the action of the Rev protein (lane 3, 4 and 5), as shown by the diminished expression of the 72-amino-acid form of the Tat protein.

The ability of these *trans*-dominant Rex mutants to block HIV-1 viral replication was also studied (Fig. 5*c*). Replication of a Rev-deficient HIV-1 provirus, pHXB2-Bam-p3 (ref. 14), in the presence of Rex and graded amounts of *trans*-dominant Rex

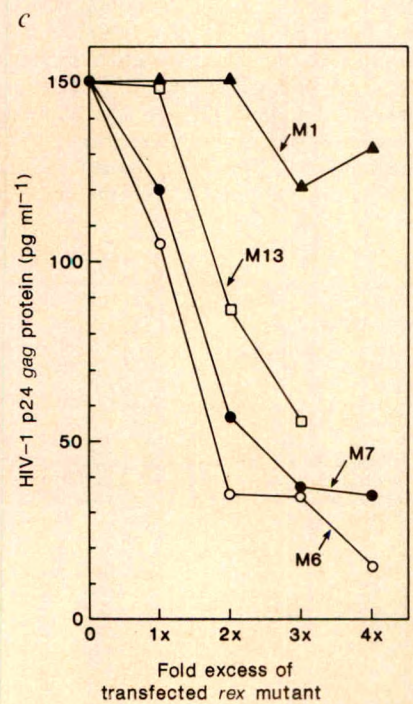

FIG. 5 *a*, Analysis of the ability of the *rex* mutants to inhibit function of the wild-type Rex protein. COS cultures were co-transfected with three plasmids, including pgTAX-LTR (1.25 μg ml^{-1}), pREX (0.1 μg ml^{-1}) and 1 μg ml^{-1} of the Rex mutants (lane 1–6), pREX (lane 7), pREV (lane 8) or pCMV-IL-2 (lane 9). HTLV-I Env production was analysed by immunoprecipitation with the 0.5-alpha monoclonal antibody and then analysed by electrophoresis through an SDS-10% polyacrylamide gel. *b*, The HTLV-I Rex trans-dominant mutants inhibit the function of the HIV-1 Rev protein. COS cells were co-transfected with pgTAT, pREV, and a 10-fold molar excess of pBC/CMV IL-2 or the M6, M7 and M13 *trans*-dominant Rex mutants. After 48 h in culture and biosynthetic labelling with [^{35}S]cysteine, cellular extracts were assayed by immunoprecipitation for Rev-induced production of the truncated 72-amino-acid form of the Tat protein (72aa, lane 2; ref. 15). At a 10:1 molar ratio, the M6, M7 and M13 (lanes 3–5) completely inhibited the action of the HIV-1 Rev protein, because only the full-length 86-amino-acid (86aa) form of the Tat protein was detected. *c*, The HTLV-I *trans*-dominant Rex mutants block Rex rescue of the replication of a Rev-deficient HIV-1 provirus. COS-cells were co-transfected with the *rev*-deficient HIV-1 proviral plasmid, pHXB-2Bam-p3 (ref. 24) and pREX in the presence of the indicated fold-excess of the M1, M6, M7 and M13 mutants. Total DNA concentration in the transfection cocktail was maintained at a constant level by the addition of varying amounts of the pBC/CMV-IL-2 parental vector. Three days after transfection, supernatant levels of the HIV-1 p24 Gag protein were measured by ELISA (Coulter Immunology kit). The M6, M7 and M13 mutants produced dose-related inhibition of HIV-1 p24 production, but the recessive negative M1 mutant did not.

mutants was studied by transfection of COS cells with these plasmids. As indicated by the supernatant levels of synthesized HIV-1 p24 Gag protein, the *trans*-dominant Rex mutants (M6, M7 and M13) produced dose-related inhibition of HIV-1 replication. In contrast, the recessive negative M1 mutant of Rex was without significant effect.

These findings, together with those from the various *rex* mutants, suggest that there are at least two different functional peptide domains within the Rex protein. One domain defined by the M1 and M2 recessive negative mutations is located at the N-terminus, involves amino acids 5–7 and 14–15, and seems to play a part in targeting of the protein to the nucleus. It is also possible that this positively charged domain may be involved in Rex binding, either directly to the RexRE or to other proteins that directly contact this RNA element. A second functional domain encompasses amino acids 59–60 (tyrosine-isoleucine), 64–65 (tyrosine-tryptophan) and 119–121 (threonine-phenylalanine-histidine). Alterations at each of these discrete sites (M6, M7 and M13 mutants) lead to the production of Rex proteins that lack biological activity and also display *trans*-dominant repressor properties. Of note is the fact that the five different mutations that retain full biological activity separate M6/M7 and M13 in the linear sequence of the Rex protein, raising the possibility that the interaction of these discrete regions requires proper protein folding. This domain seems to be important in the effector function of the Rex protein, which regulates HTLV-I structural gene expression.

These *trans*-dominant repressors of the HLTV-I *rex* gene thus join a small but expanding group of dominant negative mutant proteins which represent a novel class of theoretical anti-viral reagents. Specifically, *trans*-dominant mutants of the VP-16 protein of the herpes simplex virus[16], the Tax protein of HTLV-II (ref. 17), the Rev protein of HIV-1 (ref. 18), and the Tat protein of HIV-1 (ref. 19) have now been described. Should effective and safe delivery systems be developed, each of these mutant genes or proteins could in theory be used as 'intracellular immunogens'[20] to block the replication of the respective virus by inhibiting the essential function of its wild-type counterpart protein. Certain *trans*-dominant proteins might also prove active against more than one type of virus. Specifically, we have demonstrated that the HTLV-I Rex *trans*-dominants are active as repressors of Rev function in the HIV-1 system. These dominant negative Rex proteins, therefore, seem to be capable of mediating anti-viral effects in both the HTLV-I and HIV-1 systems. □

Control of topology and mode of assembly of a polytopic membrane protein by positively charged residues

Gunnar von Heijne

Department of Molecular Biology, Karolinska Institute, Centre for Biotechnology, NOVUM, S-141 52 Huddinge, Sweden

POSITIVELY charged amino acids have been shown to be important elements in targeting-peptides that direct proteins into mitochondria, nuclei, and the secretory pathways of both prokaryotic and eukaryotic cells[1]. The 'positive-inside' rule, which observes that regions of polytopic (multi-spanning) membrane proteins facing the cytoplasm are generally enriched in arginyl and lysyl residues whereas translocated regions are largely devoid of these residues[2,3], implies that the distribution of positively charged amino acids may also be a major determinant of the transmembrane topology of integral membrane proteins. If this is indeed the case, it should be possible to predictably alter the topology of a polytopic protein by site-directed insertions and/or deletions of positively charged residues in critical locations. I now describe a derivative of *Escherichia coli* leader peptidase, a polytopic inner-membrane protein, that switches from *sec*-gene-dependent membrane insertion with a N_{out}–C_{out} transmembrane topology to *sec*-gene-independent insertion with a N_{in}–C_{in} topology in response to the addition of four positively charged lysines to its N terminus.

Leader peptidase (Lep) from *E.coli*, Fig. 1, has two apolar transmembrane segments (H1: amino acids 4–22, H2: amino acids 62–76), is made without a cleavable signal sequence, and is oriented with its N- and C-terminal domains facing the periplasm (refs 4, 5 and see below). Its membrane assembly has been extensively studied; both apolar regions H1 and H2 are required for assembly[6–8] and like soluble periplasmic proteins, Lep depends on the products of the *secA* and *secY* genes for proper membrane integration[9]. To test the predictive power of the positive inside rule, I have sought to invert the topology of Lep by changing the distribution of positively charged residues from a typical N_{out}-C_{out} pattern to a N_{in}-C_{in} pattern by adding four positively charged lysines to the N terminus (between residues 4 and 5, called mutant 4K) and simultaneously removing the highly charged segment 30–52 from region P1 between H1 and H2 (mutant Δ30–52).

As shown previously[8], the 4K and Δ30–52 mutations do not by themselves affect the topology of Lep as judged by a protease-accessibility assay. The double-mutant 4K/Δ30–52, however, is completely resistant to proteases added to cells with permeabilized outer membranes (data not shown). This is consistent with an 'inverted' (N_{in}–C_{in}) topology where the large P2 domain is protected from protease attack by the inner membrane, but the location of region P1 remains undefined.

The P1 region might, even if translocated across the inner membrane, be too short and/or too tightly bound to the membrane surface to be protease sensitive. Mutant Lep' was created by adding to the Δ30–52 mutant a short spacer of eight mainly polar and one negatively charged amino acids (Gln-Ser-Leu-Asn-Ala-Ser-Ala-Ser-Glu, shown in single-letter code in Fig. 1) between residues 23 and 24 in P1. As shown in Fig. 2, Lep' behaves like its parent, the Δ30–52 mutant, and like wild-type Lep in the protease assay, demonstrating that the large C-terminal domain P2 is translocated across the inner membrane (and is therefore trypsin sensitive). When four positively charged lysines were added to the N-terminus of Lep', however, the resulting protein (Lep'-*inv*) was only trimmed to a slightly smaller form by trypsin as would be expected of a molecule with N_{in}–C_{in} topology. The protected fragment has a molecular

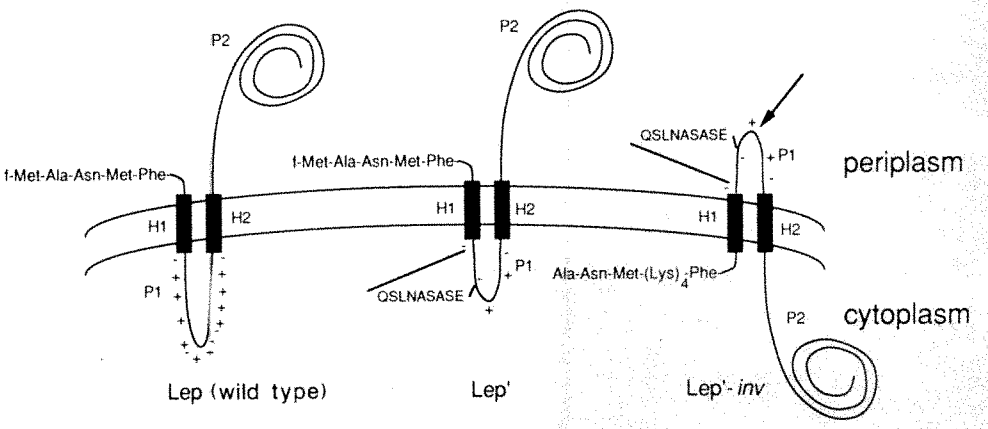

FIG. 1 Topology of wild-type *E. coli* leader peptidase, and of the Lep' and Lep'-*inv* derivatives. The trypsin cleavage site in Lep'-*inv* is shown by the arrow. N terminal amino-acid sequences, and the nine-residue spacer in Lep' and Lep'-*inv*, are indicated (single-letter amino-acid code). Mutants of Lep were constructed by oligo-directed insertions and deletions using the Kunkel method[14].

weight similar to the previously constructed Δ4–50 mutant[7], consistent with a cleavage site in the P1 region. Radiosequencing of the protected fragment unambiguously shows that trypsin cleaves after Lys 37 (Fig. 3*a*) demonstrating that P1 is exposed to the periplasm and that P2 is in the cytoplasm in Lep'-*inv*.

To localize the N-terminus of Lep' and Lep'-*inv*, I took advantage of the fact that wild-type Lep has the N-terminal sequence f-Met-Ala-Asn-Met-Phe- (ref. 4). It is known from protein sequencing that the N terminus is blocked[4]; yet, all known cytoplasmic *E. coli* proteins starting f-Met-Ala- are unblocked and have lost the f-Met[10]. A possible explanation for this anomalous property of wild-type Lep is that the N terminus is facing the periplasm and hence protected from de-formylating and Met-removing enzymes. If this is indeed the case, one would expect mutant Lep-derivatives with a cytoplasmic N terminus to be unblocked and to lack the initial Met residue.

To test this idea, Lep' and Lep'-*inv* were labelled with [^{35}S]-Met and subject to radiosequencing. Like wild-type Lep, Lep' did not give a sequence, but Lep'-*inv* gave a strong signal in cycle 3, as would be expected if the f-Met had been removed (Fig. 3*b*). As a further test, the non-translocated Δ5–22 mutant[8] lacking H1 also gave a strong signal indicating that f-Met had been removed (data not shown). Although indirect, these results suggest that wild-type Lep and Lep' have a periplasmic N terminus, whereas the N terminus of Lep'-*inv* faces the cytoplasm.

Finally, as our previous statistical studies[2,3] of polytopic membrane proteins led to the proposal that periplasmic regions shorter than 60–70 residues are translocated by a mechanism that is independent of the *secA* and *secY* genes, Lep' and Lep'-*inv* were transformed into the appropriate secA^{ts} and secY^{ts} strains. At the non-permissive temperature, translocation of Lep' and of the outer-membrane protein OmpA was blocked in both strains (Fig. 4). By contrast, the assembly of Lep'-*inv* was unaffected, confirming the prediction that translocation of the 25-residues-long P1 domain is independent of the SecA and SecY functions.

This study shows that the apolar regions H1 and H2 carry no topological information: the topology of Lep' is completely inverted when four lysines are placed at its N terminus. Although

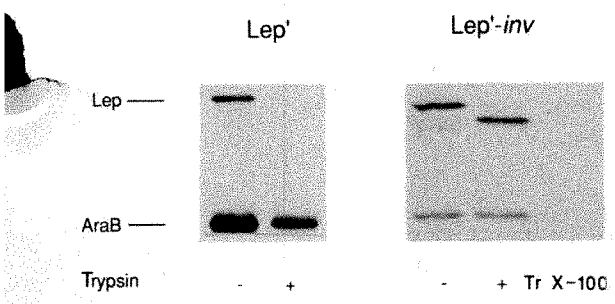

FIG. 2 Trypsin removes the P2 domain from Lep' and cleaves Lep'-*inv* in the P1 domain. The cytoplasmic protein, AraB, serves as a control for the integrity of the inner membrane. Mutants were expressed from the pING vector[15] in strain HJM114 essentially as described previously[8]. Cells were grown in M9 minimal medium supplemented with ampicillin, 0.5% fructose and all amino acids except Met to early log phase, expression of the mutant protein was induced for 5 min by addition of arabinose to 0.2% final concentration, cells were labelled with [^{35}S]Met for 2 min, injected into ice-cold sucrose–EDTA buffer to permeabilize the outer membrane and incubated with trypsin (0.75 mg ml^{-1}) (or with trypsin + trypsin inhibitor + PMSF) for 1 h on ice. Where indicated, cells were lysed by vortexing in 2% Triton X-100 (Tr X-100) before trypsin treatment. Subsequently, soybean trypsin inhibitor (1 mg ml^{-1}) and PMSF (0.8 mg ml^{-1}) was added, samples were acid-precipitated, resuspended in 10 mM Tris/2% SDS, immunoprecipitated with antiserum to Lep and AraB and analysed by SDS-PAGE and autoradiography.

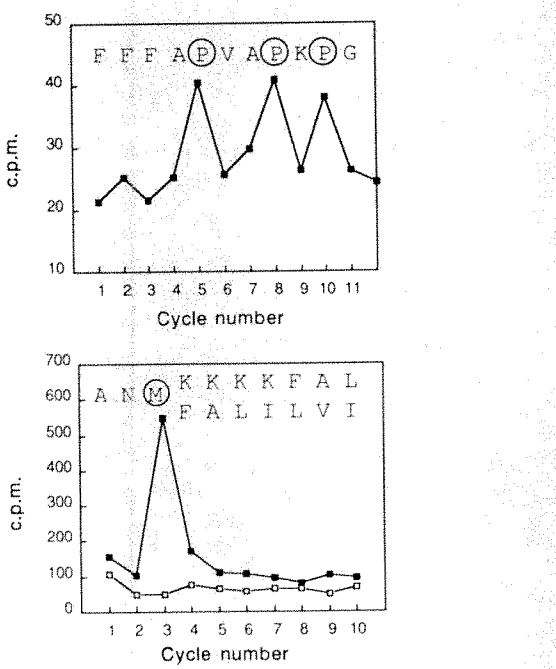

FIG. 3 N-terminal radiosequencing of the trypsin-resistant fragment from Lep'-*inv* (top) and of full-length Lep' and Lep'-*inv* (bottom, open and closed squares, respectively). The sequence following Lys 37 (top) and the N-terminal sequences following f-Met in Lep'-*inv* (bottom, upper) and Lep' (bottom, lower) are shown. Mutant proteins were expressed in strain MC1061 (0.5 ml) by induction with 0.2% arabinose for 5 min, labelled with 125 μCi [^{3}H]Pro (top) or 60 μCi [^{35}S]Met (bottom), trypsin-treated (top only), acid-precipitated, resuspended in 10 mM Tris/2% SDS, immunoprecipitated with antiserum to Lep, and sequenced on an Applied Biosystems 470A protein sequencer.

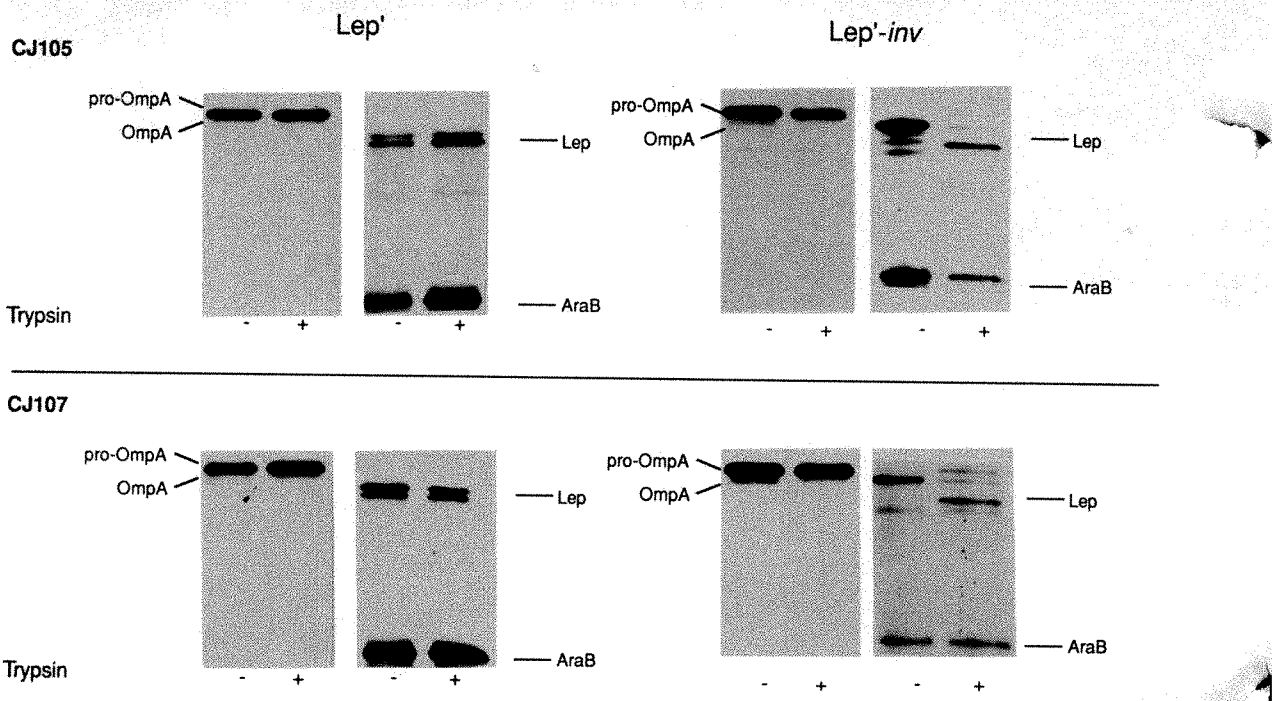

FIG. 4 Assembly of Lep' is SecA- and SecY-dependent whereas assembly of Lep'-*inv* is independent of the SecA and SecY proteins. pING plasmids encoding Lep' and Lep'-*inv* were transformed into strains CJ105 ($secA^{ts}$) and CJ107 ($secY^{ts}$) (ref. 9). Cells were grown at 30 °C to $A_{600} \approx 0.1$, and were then incubated at 42 °C for 3 h. Induction, labelling, and immunoprecipitation was done as in Fig. 1. Parallel immunoprecipitation of the outer-membrane protein OmpA and its non-translocated precursor pro-OmpA was carried out as a control of the sec^{ts} phenotypes. The doublet bands in the Lep'-lanes probably result from limited intracellular proteolysis of the non-translocated protein; similar doublets have been observed in other Lep-mutants[11].

we have not yet tested the effects of negatively charged residues, statistical[2,3] as well as experimental[11] studies suggest that their effect, if any, is weaker than that of positively charged residues. The results also strengthen the idea that short polar regions can be translocated by a *sec*-independent mechanism[2], irrespective of the size of the whole molecule[12]. Longer regions apparently can only be translocated by the normal *sec*-dependent pathway[13]. It seems, therefore, that efficient engineering of the transmembrane topology and mode of membrane assembly of polytopic membrane proteins can be based on the simple concepts of apolar membrane-spanning segments, polar flanking regions behaving according to the positive inside rule, and a critical length for *sec*-independent compared to *sec*-dependent assembly. □

ACKNOWLEDGEMENTS. Antisera were gifts from Dr Ulf Henning, Tübingen (OmpA), and from Dr Ross Dalbey, Ohio State University (Lep, AraB), who also provided technical guidance in the early phases of the project. This work was supported by the Swedish Natural Sciences Research Council and the Swedish National Board for Technical Development.

Unusual helical packing in crystals of DNA bearing a mutation hot spot

Youri Timsit, Eric Westhof, Robert P. P. Fuchs* & Dino Moras

THE target sequence of the restriction enzyme *Nar*I (GGCGCC) is a hot spot for the −2 frameshift mutagenesis (GGCGCC→GGCC) induced by the chemical carcinogens such as *N*-2-acetylaminofluorene[1,2]. Of the guanine residues, all of which show equal reactivity towards the carcinogen, only binding to the 3′-most proximal guanine within the *Nar*I site is able to trigger the frameshift event[3]. We selected the non-palindromic dodecamer d(ACCGGCGCCACA), whose sequence corresponds to the most mutagenic *Nar*I site in pBR322 DNA, for X-ray structure analysis. Its molecular structure determined at 2.8 Å resolution reveals significant deviations from the structure of canonical B-form DNA, with partial opening of three G·C base pairs, high propeller twist values and sequence-dependent three-centred hydrogen bonds. This crystal structure shows a novel kind of packing in which helices are locked together by groove–backbone interactions. The partial opening of G·C base pairs is induced by interactions of phosphate anionic oxygen atoms with the amino group of cytosine bases. This provides a model for close approach of DNA molecules during biological processes, such as recombination.

The crystal structure presented here is that of the second dodecamer duplex crystallized in the B form, with a sequence and packing environment totally different from the d(CGCGAATTCGCG) dodecamer[4]. It provides a new example for the evaluation of sequence and packing effects on DNA structure. The sequence of the two complementary strands (Fig. 1) contains the six nucleotides of the *Nar*I site in the centre of the duplex. The same sequence is present in the octamer d(GGGCGCCC), which was crystalized in an A form[5].

Crystallization conditions and preliminary crystallographic data are summarized in the legend to Fig. 1. Two points should be noted: (1) Ionic strength conditions used for crystal growth are quite similar to those generally used for growing B-form DNA crystals, but the diffraction power of the crystals is strongly dependent on a correct stoichiometric magnesium/oligonucleotide ratio. The best crystals diffract to 2.8 Å when the magnesium/oligonucleotide ratio is 16. (2) There is a high sensitivity to temperature variation: lowering the temperature by a few degrees induces a phase transition with a slight rearrangement of the molecules and loss of symmetry, leading to a space group change from *R*3 to *P*31. Here we discuss the crystal structure in space group *R*3, presently refined to 15.3% for 1,101 significant reflections.

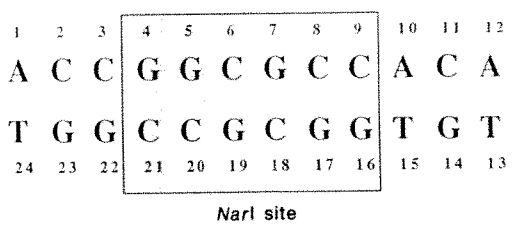
Mean values of helical parameters resemble those in canonical B-form DNA structures (Table 1). The minor groove width is 7 Å, in agreement with values found for mixed-sequence B-form DNA[6]. This value is close to that of the decamer containing two G·A mismatches (7.2 Å) (ref. 7) and to that of the phosphorothioate hexamer (6.4 Å) (ref. 8). But important deviations from standard B-form DNA[9] are observed in the centre of the helix. Figure 2*a* shows the $3F_0-2F_c$ map centred on the *Nar*I site region of the duplex. It is clear that the C6–G7–C8 step has some very unusual conformational features. The direct interaction between an oxygen atom of a symmetry-related phosphate group and the amino group of cytosine C6 induces the partial opening of the C6–G19 base pair: the distance between N4(C6)–O6(G19) is 3.7 Å, 3.3 Å for N3(C6)–N1(G19), and 2.9 Å for O2(C6)–N2(G19). The C18–G7 base pair is disrupted in the same way, with a very high propeller twist (−30°) leading to unstacking of C18 from its two adjacent base planes. The high propeller twist value of G7 and G17 leads to close contact of their O6 atoms and to the partial opening of the C8–G17 base pair (with distances N4(C8)–O6(G17) equal to 3.7 Å, N3(C8)–N1(G17) to 3.2 Å, and O2(C8)–N2(G17) to 2.9 Å). This distorted base pair seems to be stabilized by a cross-strand, three-centred hydrogen bond (N4(C8)–O6(G16) distance = 3 Å) and by a partially hydrated magnesium ion bridging the O6 atoms. The overall conformation is further stabilized by three-centred hydrogen bonds. Figure 2*b* and *c* shows the high propeller twist value of each base pair, which allows the formation of non-coplanar hydrogen bonds. Distances between N4 (C8) and O6(G16), N4(C9) and O4(T15), N6(A10) and O6(G14) are all ~3 Å. These interactions are strongly sequence-dependent and concern half of the helix from C6 to A12. Three-centred hydrogen bonds have already been observed in other B-form DNA structures having A-tract sequences[10–12], A-T tract sequences[6] and mismatched G·A pairs[7]. The results presented here extend the possibility of forming a network of three-centred hydrogen bonds to mixed sequences, including G·C base pairs, in a sequence-dependent manner.

These perturbations are probably induced and stabilized by

TABLE 1 Helical parameters of the dodecamer

	Roll (deg)	Tilt (deg)	Propeller twist (deg)	Twist (deg)	Rise (Å)
A1–G24	0	−4	−5	34	2.9
C2–G23	11	3	−20	35	3.7
C3–G22	3	−4	−26	38	3.5
G4–C21	−2	−4	0	33	3.1
G5–C20	1	4	−8	33	3.5
C6–G19	10	1	−7	35	3.7
G7–C18	2	−3	−30	36	3.2
C8–G17	3	1	−17	37	3.5
C9–G16	7	−2	−13	39	3.4
A10–T15	0	0	−14	28	3.3
C11–G14	6	1	−6	38	3.2
A12–T13	—	—	−17	—	—
Mean value	3.7	−0.6	−13.6	35.0	3.4

Helical parameters were calculated with the program NEWHELIX (distributed by R. E. Dickerson); nomenclature follows the Cambridge Conventions[16].



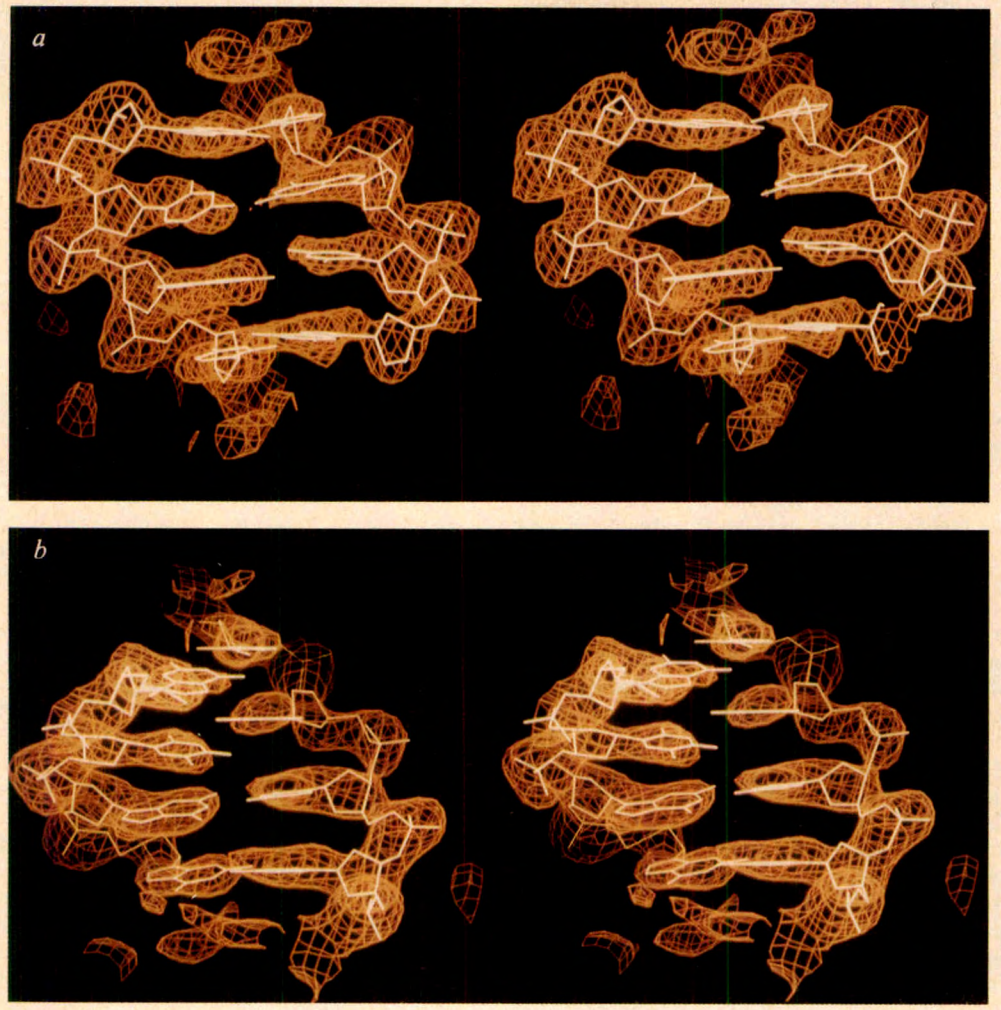


FIG. 1 Sequence of the dodecamer. The two complementary strands were synthesized by the phosphoramidites method. Single crystals were grown at 4 °C by the vapour diffusion technique from a solution containing 50 mM cacodylate at pH 6, 1 mM dodecamer duplex, 1.2 mM spermine tetrachloride and 18 mM magnesium acetate equilibrated against a reservoir of 45% 2,4-methylpentanediol. Crystals appeared in two or three days and grew during three weeks to reach 500 × 200 × 200 μm. The best diffracting crystals (2.8 Å) are produced at a magnesium/oligonucleotide stoichiometric ratio >16:1. For lower ratios, crystals only diffract at low resolution. Space group is *R*3, with cell dimensions: $a = b = 65.9$ Å, $c = 47.1$ Å, and one duplex per asymmetric unit.

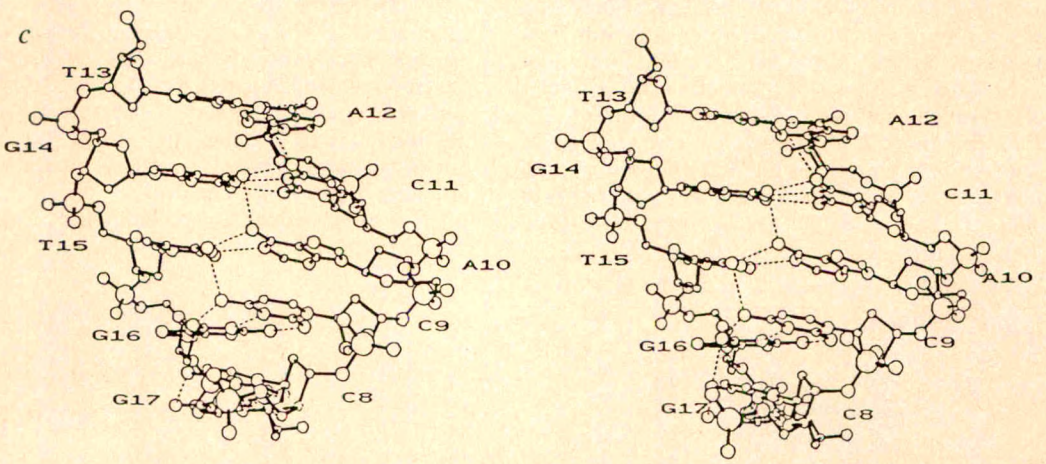

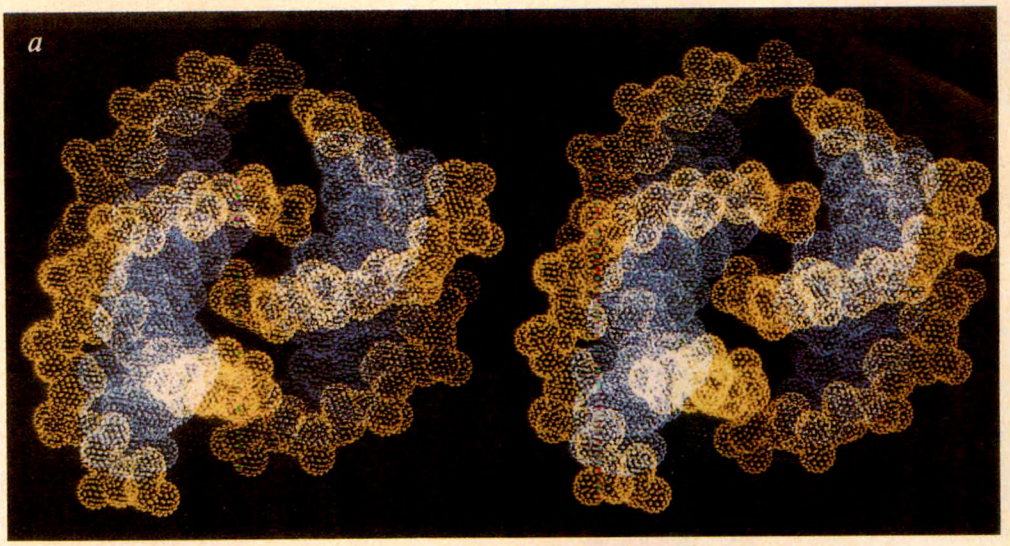

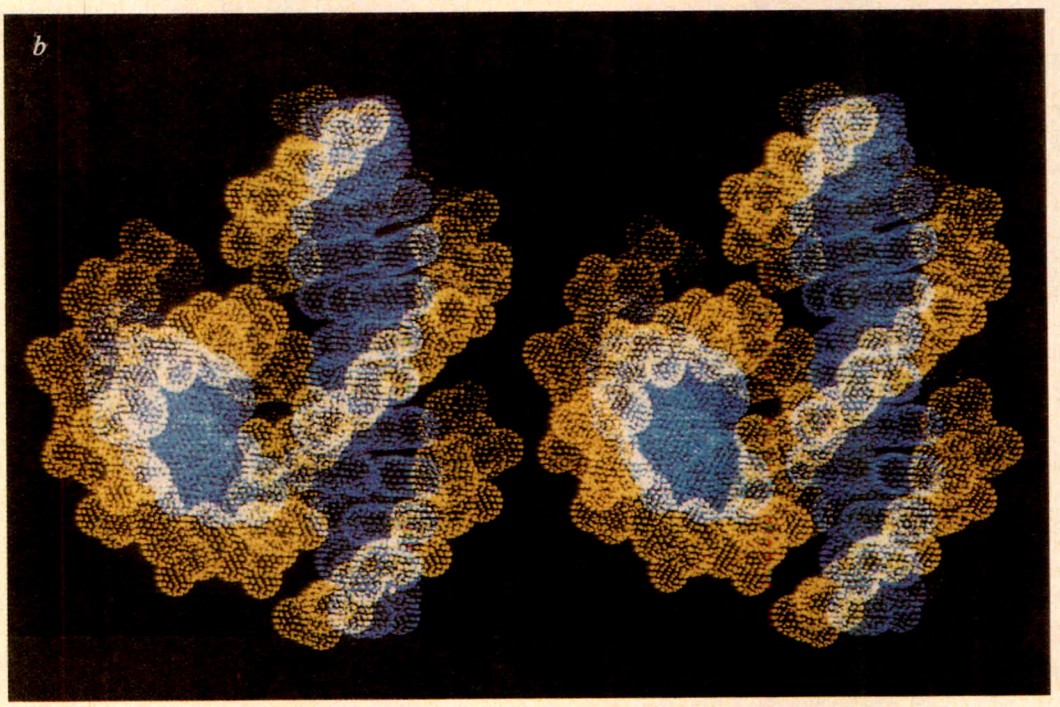

FIG. 2 *a*, $3F_o-2F_c$ map centred on the *Nar*I site region of the duplex, from the G5–C20 pair (bottom) to the C8–G17 pair (top). This stereo view of the major groove shows the unstacked C18 base with high propeller twist (30°), which leads to the disruption of the G7–C18 pair. *b*, $3F_o-2F_c$ map showing high propeller twist and three-centred hydrogen bonds, from the C8–G17 pair (bottom) to the C11–G14 pair (top). *c*, Stereo drawing of the sequence-dependent array of three-centred H-bonds. Cross-strand distances are N4(C8) to O6(G16), 3 Å; N4(C9) to O4(T15), 2.6 Å; N6(A10) to O6(G14), 2.7 Å, N4(C11) to O4(T13), 3.3 Å.

METHODS. Data were collected at 0 °C on a Nicolet detector, using three crystals. 1,584 independent reflections with R_{sym} on intensity equal to 7.7% were obtained above the 1σ level. The structure was solved by molecular replacement using the program ULTIMA (ref. 17), with a standard B-form DNA adapted from the fibre model of Arnott[9], with the proper sequence. Rigid body refinement led to an *R* factor of 21% for the 25–10 Å data. The refinement was continued with the molecular dynamic program GROMOS (ref. 18) using 10–3.5 Å data above the 4σ level (I_{obs}), to reach *R* factor of 13%. Resolution was gradually extended to 2.8 Å for further refinement with the NUCLSQ program[19]. No restraints were placed on base pairing. From the two possible orientations around the pseudo 2-fold axis of the helix, we kept the one that gave an unambiguously better fit on all three terminal base pairs. Further stereochemical arguments have confirmed this choice. Final *R* factor with 1,101 reflections above the 3σ level (I_{obs}) reached 15.3% and 19.6% with the 1,584 reflections above 1σ (I_{obs}). The cluster of 30 strong reflections in 3.4 Å area was eliminated from the data above the 3σ level used for $3F_o-2F_c$ map calculation. Twenty water molecules and one hydrated magnesium could be located on difference Fourier maps. Final coordinates will be sent to the Brookhaven Protein Data Bank.

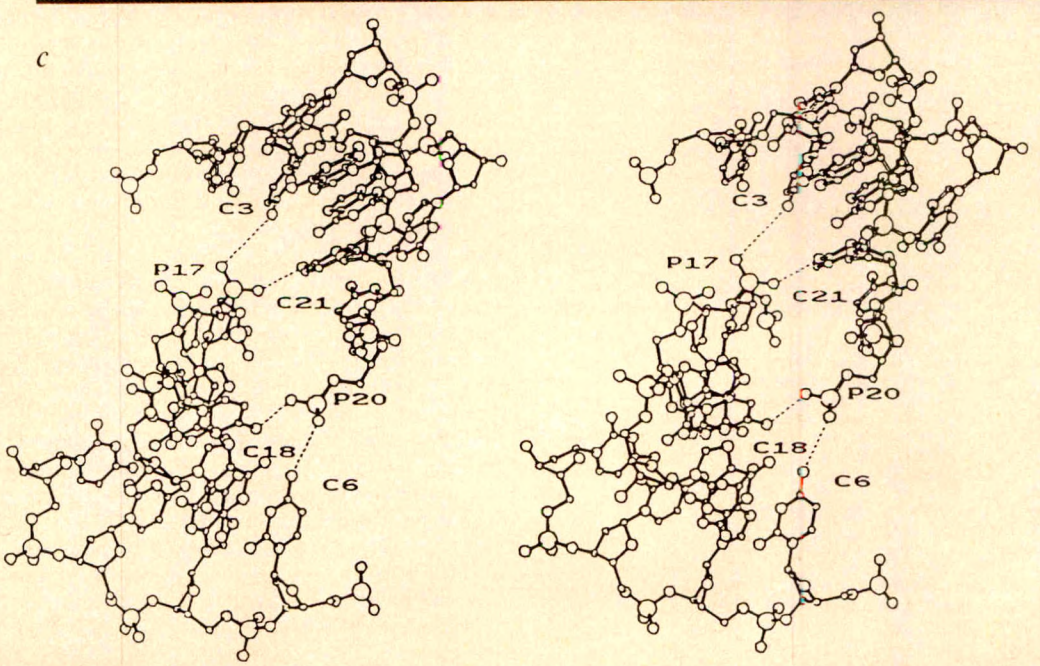

FIG. 3 *a* and *b*, Stereo views of the van der Waals representation of two symmetry-related molecules locked together by reciprocal groove–backbone interactions. The helical axes of the two molecules form an angle of 60°. *c*, Stereo view of the sequence-dependent intermolecular contacts between two symmetry-related molecules. Hydrogen bonds formed between oxygen atoms of phosphate groups of C17 and C20 and the amino N4 atoms of cytosines C3, C21, C6 and C18 are shown by dashed lines.

packing forces, and so crystallization selected one structural state among the various conformations possible for this sequence. Our crystal structure could be viewed as a snapshot picture of a CGC motif in a 'transition state' before base-pair opening. Two types of intermolecular contacts are present in the crystal packing: the end-to-end stacking of duplex molecules forming a pseudo-continuous helix, and the groove-backbone interactions, by which symmetry-related molecules are locked together as a result of shape and electrostatic complementarity between the backbone and the helix grooves (Fig. 3*a* and *b*). Direct interactions involving the N4 atoms of cytosines of one molecule and oxygen atoms from phosphate groups of a second molecule form the shortest intermolecular contacts. Figure 3*c* shows a detailed view of the sequence-specific packing contacts. It can be seen that alternate cytosines point in the major groove and interact with the phosphate group in a sequence-dependent manner: in the major groove of one molecule, N4 atoms of C18 and C6 interact with O1P and O2P atoms of C20 of a symmetry-related molecule. In the major groove of the second molecule, the same interaction is reversible between the N4 atoms of C3 and C21 and the oxygen atoms of the phosphate group of G17. The distances between the amino group and the anionic oxygen atoms of the phosphate groups are all ~3 Å. Indirect contacts involving both a magnesium ion and a water molecule bridge the O6 of G17 and the O1P atom of G19.

The new type of oligonucleotide packing observed in this structure, where helices are locked together in a sequence-dependent manner, presents an interesting analogy with the major groove-α-helix interactions found in repressor-operator complexes[13,14], in which important deviations of base-pair geometry with three-centred hydrogen bonds are also found. Furthermore, it provides a new model for close approach between helices as found, for example, during recombination, and extends the concept of specificity of molecular recognition to DNA-DNA interactions. Also, there might be a similar magnesium requirement influencing the stability of this crystal packing and the intermediate stages of recombination[15]. Alternate NH_2 groups in the major groove and magnesium ions might play an important part in specifying and stabilizing the Holliday junction. This crystal structure also illustrates how the introduction of a phosphate group in the major groove could provide an easy way to initiate denaturation through stabilization of open base pairs.

In addition, it is tempting to conclude that the pronounced deviations from the standard B-form DNA structure in the centre of the *Nar*I site are related to the mutation-hot-spot properties of this sequence. Indeed, these peculiar structural properties may favour the induction of a specific conformational change when N-2-acetylaminofluorene is bound to G7, the only binding event triggering mutation[3]. □

The α-lytic protease pro-region does not require a physical linkage to activate the protease domain *in vivo*

Joy L. Silen & David A. Agard

Department of Biochemistry and Biophysics, and

San Francisco, California 94143, USA

α-LYTIC protease, an extracellular serine protease of *Lysobacter enzymogenes 495*, is synthesized as a pre-pro-protein[1]. Previously it has been shown that when expressed in *Escherichia coli*, the protein is autocatalytically processed in the periplasmic space, and that the functional protease domain accumulates extracellularly[2]. Engineered proteins lacking the 166 amino-acid pro-region were enzymatically inactive and remained cell-associated[2]. By independently expressing the pro- and protease domains *in vivo*, evidence is provided here that direct covalent linkage is not required for production of active protease. We postulate that the pro-region acts as a template to promote the folding of the protease domain into an active configuration. Our results, combined with recent experiments on the evolutionarily unrelated subtilisin E (ref. 3), suggest that the ability of the pro-region of these bacterial proteases to facilitate folding of their protease domains is not a curiosity of a single system, but may reflect a general property of extracellular bacterial serine proteases.

On the basis of denaturation and renaturation experiments on a wide variety of small proteins[4–6], it seems that small, single-subunit, globular proteins fold spontaneously to reach a minimum energy state. For example, Anfinsen demonstrated that ribonuclease A could be unfolded and then refolded with full restoration of activity[4]. Unexpectedly, two small bacterial serine proteases, subtilisin (J. Wells, personal communication) and α-lytic protease (J. Richards, personal communication) could not be refolded. Experiments in both systems[2,7] indicated that the pro-region, which is covalently attached to, but only transiently associated with the protease domain, is necessary for correct folding of these enzymes. Several different models can be proposed for the role of the pro-region in folding the protease domain (Fig. 1). In models 1 and 2, the properly folded protease is considered to be at an energy minimum, but is kinetically inaccessible. That is, there are one or more non-productive folding pathways leading to improperly folded and possibly aggregated protein that have a lower transition-state energy and higher ground-state energy than the productive pathway. The pro-region would then facilitate production of active protease, either by stabilizing the transition state for the correct pathway (Fig. 1, model 1) or by destabilizing the non-productive pathways (Fig. 1, model 2). Unfortunately, it is not yet possible to distinguish between these two models as this requires a detailed kinetic analysis using purified components. Model 3 (Fig. 1*a*, *b*), however, which depends on the energy liberated from cleavage of the precursor, can be tested. In this model, the functional protease is not at an energy minimum (the misfolded forms on the non-productive pathway have lower energies), but is kinetically trapped. In such a model, the pro-region would act as in model 1 to lower the kinetic barrier, but in addition, the energy released by cleaving the precursor is required to shift the overall equilibrium in favour of the productive pathway. Once formed, the active high-energy protease would be unstable in the presence of functional pro-domain (Fig. 1*b*). To avoid unfolding active protease and subsequent accumulation in the lower-energy misfolded state, the pro-region must be physically separated from the protease or inactivated.

To test if the physical linkage and its subsequent cleavage

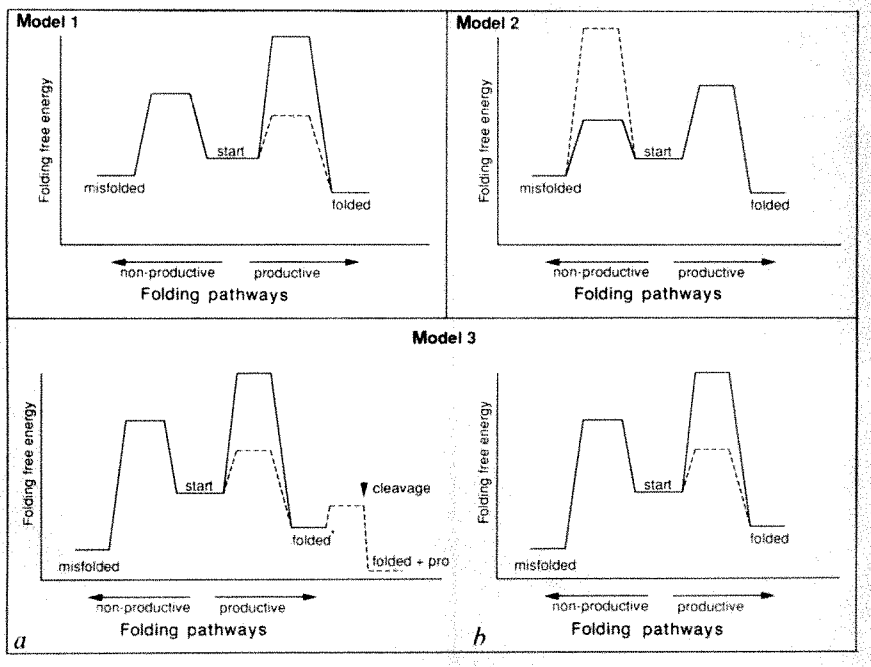

FIG. 1 Three models for the role of the pro-region in folding the protease domain. In all cases the folding process is considered to be a competition between a productive folding pathway that leads to the correctly folded protease, and a non-productive pathway that leads to misfolded and/or aggregated inactive protein. The free energy of folding from the point of view of the protease domain is shown in the absence (solid lines) and presence (dashed lines) of the pro-region. In model 1, the pro-region is seen to stabilize the transition state for folding, whereas in model 2 the pro-region destabilizes the transition state for the competing non-productive pathway. Models 1 and 2 are independent of the covalent attachment of the pro-region and thus, for simplicity, the energetics of the pro-region cleavage are not included. Model 3, depicting a kinetically trapped, higher energy folded state, is shown with either a covalently attached pro-region (panel *a*) or with a non-linked pro-region (panel *b*). The energy of bond cleavage can be used to shift the overall folding equilibrium in favour of the folded configuration only if the pro-region is covalently attached (*a* versus *b*). In model 3 there must be a folded (or mostly folded) intermediate that is still covalently linked to the pro-domain (folded* in panel *a*), which after cleavage results in the final, active form of the protease.

plays a direct part in the folding process (model 3), it was necessary to independently express the pro- and protease domains within the periplasmic space. Expression systems with signal sequences were employed because the protease has three disulphide bonds and thus requires an oxidizing environment to fold properly. The expression construct, pCOMP5 (Fig. 2), uses the *phoA* promoter and signal sequence fused to the protease domain[2] and the *lpp/lac* promoter and *ompA* signal sequence[8] fused to the pro-region. This construct allows induction of the pro-region by isopropyl-β-D-thiogalactoside (IPTG) and the protease domain by phosphate starvation. Only the dual conditions of phosphate starvation and IPTG induction would allow complementation and, therefore, accumulation of the active enzyme.

The results of the induction experiment are shown in Fig. 3. As expected, independent induction of either the protease or pro-domains results in little or no activity. The low level of proteolytic activity seen in the low-phosphate control culture, in which only the protease domain is induced, probably results from the basal expression of the pro-region by the *lpp/lac* promoter[8]. In the cultures containing low phosphate plus IPTG, in which both promoters are induced, α-lytic protease activity reaches levels more than 30 times that of the low-phosphate control culture. As the accumulation of active α-lytic protease occurs after the addition of IPTG and follows the induction of cellular alkaline phosphatase, it is clear that co-induction is required for α-lytic protease production.

These experiments, and the *in vitro* experiments with subtilisin[4], demonstrate the independence of the folding process from the direct linkage between the pro- and protease domains, thereby eliminating the kinetic trapping model (Fig. 1, model 3). By uncoupling the irreversibility of bond cleavage from the folding process, the thermodynamics of folding of the protease domain can be more accurately considered, and more easily

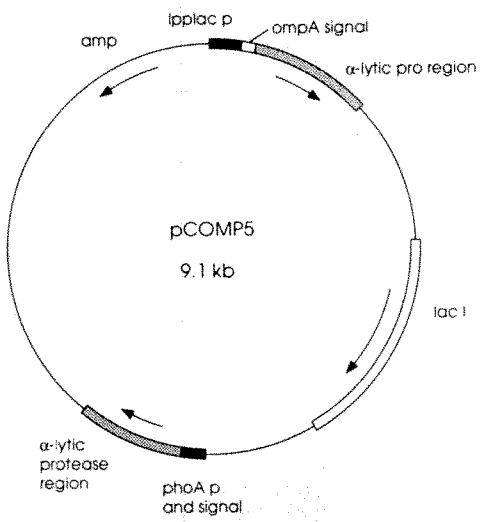

FIG. 2 The pCOMP5 plasmid (9.1 kilobases). This pIN-III-ompA2 derivative[8] places the pro-region of α-lytic protease under the control of the IPTG-inducible *lpp/lac* promoter and downstream of the *ompA* signal sequence. The protease domain of the α-lytic protease gene is fused to the *phoA* promoter and signal sequence; its expression depends on depletion of phosphate in the medium.

METHODS. The pro-region was originally isolated as a filled-in *Eae*I fragment from pDA13 (ref. 1) and cloned into a modified pDBR2 cut with *Sma*I and *Eco*RI (blunted). This construct (pPRO1) established *phoA*-promoter controlled expression and placed an in-frame stop codon six amino acids from the end of the pro-region. A filled-in *Eae*I-*Ball* fragment from pPRO1 was cloned into the filled-in *Eco*RI site of pINIII-ompA2, which placed it in frame with the *ompA* signal sequence (pPRO3). The coding region for the protease domain of α-lytic protease was added to pPRO3 at a unique blunted *Sty*I site by transferring in a filled-in *Not*I–*Nar*I fragment from pMALP4 (a derivative pMALP2 (ref. 2). Orientation of the protease-encoding fragment was established by restriction enzyme analysis. Constructs were transformed into *E. coli* strain HB101 (*recA*$^-$) for expression.

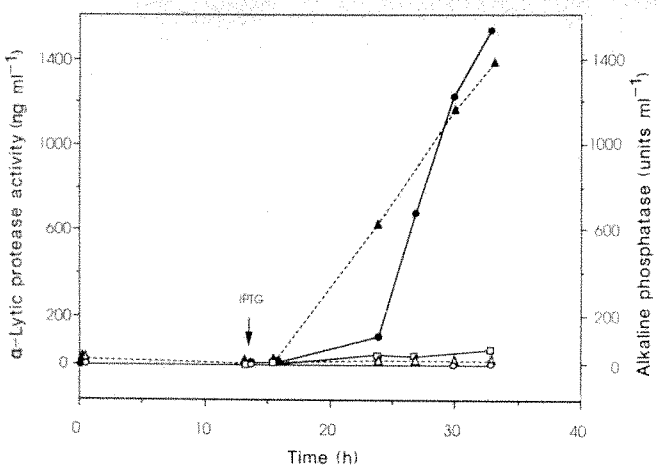

FIG. 3 Time course of α-Lytic protease and alkaline phosphatase production in cultures of HB101/pCOMP5. As the exact time of phosphate depletion is uncertain, levels of chromosomal alkaline phosphatase (--▲--) were monitored to follow the time course of the induction of the *phoA* promoter. Alkaline phosphatase levels under non-inducing conditions (high phosphate plus IPTG) remained at baseline levels (--△--). α-Lytic protease production was also monitored as a function of time: significant levels of activity are seen only when both the pro- and protease regions are co-expressed (compare low phosphate plus IPTG (—●—) with phosphate plus IPTG (—○—) or low phosphate alone (—□—)).
METHODS. Cells grown overnight in high-phosphate medium were concentrated, resuspended in low-phosphate medium, and diluted 1:100 in 250 ml low phosphate (0.1 mM K_2HPO_4/KH_2PO_4, pH 7.2) MOPS medium, or directly diluted 1:100 in 250 ml of high phosphate (20 mM K_2HPO_4/KH_2PO_4, pH 7.2) MOPS medium to an identical optical density at 600 nm ($OD_{600}=0.04$). Four 50 ml aliquots of the low-phosphate culture were taken into 500 ml shaker flasks for duplicates of the low-phosphate and low-phosphate-plus-IPTG cultures; two 50 ml aliquots of the high-phosphate culture were used for the high phosphate duplicates. Cultures were grown with shaking (200 r.p.m.) at 22 °C. After 14 h ($OD_{600}=1.0$), IPTG (2 mM final concentration) was added to the duplicate high-phosphate cultures and to one pair of the low-phosphate cultures. Levels of alkaline phosphatase (both from the cells and the medium), and α-lytic protease (medium only) were determined as previously described[2], using *p*-nitrophenyl phosphate and suc-Ala-Pro-Ala-*p*-nitroanalide, respectively, as substrates (α-lytic protease purified from *Lysobacter enzymogenes* has 188 units mg^{-1}; 1 unit hydrolyses 1 μmol substrate per min). Data shown is the average of the duplicate cultures, except for the low-phosphate culture alkaline phosphatase induction, which is the average of all four low-phosphate cultures, plus and minus IPTG.

investigated experimentally. Because active α-lytic protease displays remarkable temperature stability[9], resistance to autolysis and a high degree of structural rigidity[10], there is probably a high-energy barrier close to the folded state that provides the active enzyme with its high stability, as in model 1. Apparently, this barrier is too high to be traversed unaided. Thus, the pro-region can be thought of as a template that preferentially binds to, and stabilizes, the transition state for folding, just as an enzyme binds and stabilizes the transition state for catalysis of a reaction.

It is quite remarkable that these two classes of serine protease[5], which are unrelated in structure and sequence, have, through convergent evolution, developed both a spatially identical Asp-His-Ser catalytic triad and what appears to be a similar folding mechanism. Molecular analysis of the genes for a wide variety of secreted proteases from both Gram-positive and Gram-negative bacteria[11-18] reveals that these enzymes are also synthesized in precursor form. The widespread use of pro-regions by extracellular bacterial serine proteases indicates that these domains must have an extremely important function.

The folding activity of these pro-regions is reminiscent of the recently discovered class of proteins, called chaperonins, which facilitate the folding and assembly of multi-subunit proteins in chloroplasts[19], mitochondria[20] and of bacteriophage in *E. coli*[19]. Although the chaperonins are capable of aiding the folding of a number of proteins, these extracellular bacterial serine proteases seem to have evolved their own specialized folding aids which are covalently attached. Further examination of the structure and mechanism of the α-lytic protease pro-region may provide new insights into the function of other more generalized folding and assembly systems. □

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

Modelling in peptide design

B. A. Jameson

Powerful molecular modelling software can be used to visualize the tertiary structures of biologically significant proteins, with important implications for rational drug design.

THE increasing database of crystallized protein structures combined with the increasing user-friendliness of powerful computer algorithms designed to calculate folding patterns of proteins has created an environment in which the empiric art of peptide and drug design is being replaced with designs based on shape. There is a current trend towards protein engineering where, for example, the goal is to change a protein's shape in order to alter its biological activity. Altering activity, however, requires extensive assumptions about a protein's mechanistic details that often extend far beyond available information. The goal of isosteric (same-shape) analogue design, on the other hand, is to mimic, not alter, the shape of a protein. This requires less guess-work and is, consequently, a more feasible approach at present.

In order to design an isosteric analogue of a protein, a template structure must, obviously, be available. Although the number of protein structures being deposited in the protein databank at Brookhaven National Laboratory is increasing at an astounding rate, the total number of available structures is still limited. Molecular modelling based on homology is a powerful means of extending this structural database. Recently, a high-resolution crystallographic structure of HIV-1 protease became available[1]. Before the availability of this structure, there were two published reports of molecular models of this protein based on the assumption that backbone folding patterns within a given family of proteases is conserved. In one case a distantly related pepsin structure was used as a folding template[2], and in the other case a more closely related retroviral protease was used[3]. In both cases, the high-resolution crystal structure showed that these predicted structures were remarkably accurate. In this manner the structural database can be expanded to include evolutionarily related protein family members and, thus, increase the general applicability of rationally designed synthetic peptides.

Modelling parameters

There are currently five major software packages available for molecular modelling (BioDesign, Inc., Pasadena, California; Biosym Technologies, San Diego, California; Tripos, St. Louis, Missouri; Polygen, Waltham, Massachusetts; and Chemical Design Ltd, Oxford, UK). All of the molecular modelling packages operate by using three basic parameters: a descriptive energy field, an algorithm for performing molecular mechanics and an algorithm for performing molecular dynamics[4,5].

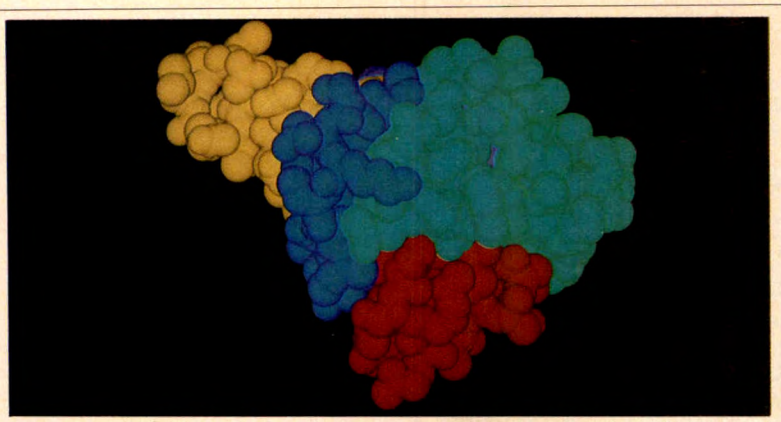

FIG. 1 Molecular model of the V_1 domain of the CD4 protein (residues 1–104). The model was constructed using an immunoglobulin light chain variable domain homodimer (Brookhaven database code: REI, Epp[13]) as the backbone template and using the molecular modelling package Biograf (BioDesign, Inc., Pasadena, California).

The first component of a modelling package, the energy field, involves a set of parameter tables that are used to create mathematical descriptions of atoms and their potential interactions with one another based on averaged values determined from known structures. One of these parameter tables is an atom data file. This file contains descriptions of individual atoms, such as their partial charge, mass and type. Such tables provide the basic information necessary appropriately to represent the stereochemical properties of each atom. For example, carbon–carbon interactions with sp^3 and sp^2 hybridizations need to be distinguished (single bond versus double bond) in terms of geometry, bond strength, ideal strength and other parameters. A bond description file is used in depicting the covalent structure of the molecule on the basis of the number and type of covalent bonds occurring between atom pairs. This type of table also includes descriptions of the 'spring-like' properties of various bonds and favourable and unfavourable torsional rotations. Finally, there is a table used in the consideration of nonbonded interactions such as van der Waals and electrostatic attractions.

The second and third components of the modelling package involve energy minimization functions, molecular mechanics, and energy-dependent molecular motion simulations and molecular dynamics. The theoretical goal of molecular mechanics is to calculate a local energy minimum for a given structure. Due to the number of independent variables and quantum mechanical considerations, such calculations are not truly feasible and must be simplified. The algorithms used in treating potential energy functions of a structure through molecular mechanics serve to reduce or eliminate steric conflicts and adjust bond lengths and bond angles to approximate their ideal values. Generally, this technique will not produce structures grossly different from the initial structure. Molecular dynamic calculations are used to alter backbone structures. These programs rely on many of the same basic parameters as mechanics, except that temperature, pressure and atomic velocities are included in the calculations as a function of time. Typically, these calculations are performed repetitively in 0.002 ps stepwise intervals.

There are quite a few practical restrictions placed upon the modelling algorithms. One of the greatest limitations is that most of the spontaneous protein folding events in nature occur on a nanosecond time scale. Outside of calculations performed on Cray supercomputers (which are also time-restricted), most computational times are limited to under 100 ps. This means that a substantial body of information should be known about the protein's folding properties, such as its backbone folding architecture, before attempting to create a protein model. There exists a commonly held belief that the computer modelling algorithms are capable of taking a linear amino acid sequence and predicting a meaningful tertiary structure. Such is not the case. Understanding the basic limitations of these folding techniques is critical to producing a meaningful structure.

Our laboratory has been studying the

binding events that occur between the envelope protein (gp120) of the virus causing AIDS (HIV) and its cellular receptor, the CD4 protein. It has recently been shown that the first 104 amino acids of the CD4 protein are sufficient to account for the high-affinity interaction observed in binding to the gp120 protein[6]. This region of the CD4 protein is a part of the immunoglobulin superfamily of proteins[7,8]. Although a crystal structure for this protein is not yet available, its relationship to the immunoglobulin family of proteins and the fact that it is a small, well-defined region make it an ideal candidate for molecular modelling. Our computer-generated model of this protein is shown in Fig. 1. The regions that correspond to antigen-binding domains on an immunoglobulin protein are highlighted (blue — CDR1, red — CDR2, yellow — CDR3). The CDR2-like region projects well away from the surface of the protein relative to the parent immunoglobulin structure. Site-directed mutagenesis experiments suggest that this region is directly involved in binding to the gp120 envelope protein[6,9-11]. Our model agrees well with this finding.

We have now used the modelled CD4 protein as a template in the design of conformationally restricted synthetic peptides. This has been done by introducing artificially positioned disulfide bridges to force conformational folding of the synthetic peptide. While previously designed peptides that encompassed the linear sequence of the CDR2-like domain failed to show any effect, our crude isosteric analogues appear to have biological activity[12].

The work described above serves as an illustrative example of the limitation and potential power of the use of molecular modelling techniques. The protein, whose structure is unknown, belongs to a larger evolutionary family of proteins that include members with established structures. Biological data has defined a discrete subdomain of the protein for analysis, thus limiting the scope of the modelling problem. Perhaps most importantly, there exist biological assays to test the validity of the structural model. We feel that this type of approach can be successfully applied to a variety of different systems, and it may be possible to create powerful new peptide analogues for understanding structure/function relationships as well as reagents that may have useful applications as therapeutic drugs. □

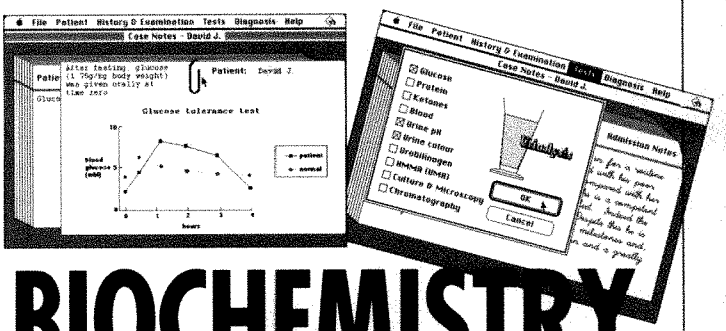
Creative computing

A robotic titration workstation and 3-D molecular modelling software are a selection of what next week's Scientific Computing and Automation Conference in Philadelphia, Pennsylvania, has to offer.

Sun Microsystems, Inc. are emphasizing the compactness, high-performance capabilities and affordability of the SPARCstation 1 **desktop computing system**, which can be seen in booth 311 (*Reader Service No. 101*). Geared to reduced instruction set computing and delivering 12 million instructions per second, the $8,995 (US) SPARCstation 1 provides, says the company, enhanced productivity for chemical database management, low-end molecular modelling, electronic publishing of technical findings and laboratory management. Special features include multitasking and windowing capabilities which allow several applications to be performed simultaneously in different windows. The SPARCstation 1 is binary compatible with all other SPARCsystem workstations and Sun-4 family machines, and will run Sun software and a range of third-party software. An optional DOS Windows emulation package is available.

World Precision Instruments, exhibiting in booth 628, will be featuring WavEdit — new **software for reviewing and editing data** recorded in Apple Macintosh files (*Reader Service No. 102*). The $395 (US) waveform editing software can open files created by WPI data acquisition systems as well as any 12-bit data files that are saved in text or binary format. Regions of interest are selected using cursors and scrolling and indexing functions. Selections are then cut, copied and pasted into a new window. Recordings appear as chart recorder-type displays, which can be overlaid, displayed side-by-side, or compared numerically. According to WPI, the integrity of the original data is maintained as WavEdit does not delete or modify the raw data file. The software will run on any Macintosh computer that has at least one MByte of memory, however, the company says that the performance can be enhanced by using Macintosh II, IIx, or IIcx hardware. A demo version of WavEdit is available from WPI for a nominal price.



Review and edit data with WaveEdit software from WPI.

Source for Automation, Inc. will be showing off their new general purpose **robotic titration workstation** in booth 226 (*Reader Service No. 103*). Titration routines can be tailored to individual requirements by selecting from a range of sample preparation procedures, including grinding, heating, cooling, weighing, shaking, stirring, vortexing, diluting and filtering. Samples are identified by barcodes. The system then searches for the relevant titration routine, prepares the sample, and places it in the titration head, with automatic presentation of the cup to the probes. Liquids are transferred by peristaltic transfer by volume or weight, or by syringe pump or burette by volume. The workstation automatically records results and performs calculations, and allows users to create individualized report formats. The general purpose titration workstation costs about $40,000 (US) and can function as an unattended standalone system or as part of a network.

Molecular modelling

Visitors to Molecular Design Ltd's booth, number 112, will be able to see the latest addition to the graphics-based MACCS II **chemical information management system** — MACCS-3D (*Reader Service No. 104*). The software can be used for storing, searching and retrieving 3-D chemical

How to keep your biochemistry classes awake . . .

CASE NOTES IN BIOCHEMISTRY

Teaching software for courses in pre-clinical medicine

Four modules for IBM® PC (running Microsoft® Windows) and Apple Macintosh®

Case Notes in Biochemistry will help make sure that by the end of their pre-clinical/basic science courses your students have gained a thorough understanding of the role played in medicine by biochemistry.

The software models "patients" with the symptoms of particular conditions: students find their way through encounters with these patients, eliciting their symptoms and calling for crucial biochemical tests in order to reach diagnoses.

FOUR MODULES:

- **Glycogen storage disease (type 1)**
- **Coma**
- **Jaundice**
- **Diabetes**

Each module simulates a number of patients with the symptoms of a particular condition. For each patient the system can produce the notes of the physician that referred the patient, his or her history and the notes that would be taken at an examination. To acquire the information needed to reach a diagnosis, the user must ask the software to model the appropriate tests.

The example conditions and the standard diagnostic tests associated with them are already used widely in conventional teaching at this level. Too frequently, however, students do not retain the content of lectures and textbooks. **Case Notes in Biochemistry** addresses the teaching process in another way, encouraging students to think for themselves and learn more actively. It makes the students' success dependent on their own decision-making and increases their enthusiasm and commitment to the course.

Case Notes in Biochemistry uses the elegant interface between user and software provided as standard by the Macintosh and, on PCs, with MS-Windows. This creates a learning environment where students can intuitively find their way. Visual cues and conventions encourage rapid involvement and whole-hearted entry into the simulation.

ACADEMIC DISCOUNT 20% ACADEMIC DISCOUNT

AUTHORS

Dr Andrew Booth: senior lecturer and director of the Biochemistry Microcomputer Group in the Department of Biochemistry at the University of Leeds, UK. He is the author of several teaching software packages in biochemistry.

Dr Jonathan Danks: principal of a family practice in Leeds.

DEMONSTRATION DISKS

To find out for yourself if **Case Notes in Biochemistry** could put extra life into your biochemistry classes, you will need a demonstration disk: use the coupon below to request a copy.

TECHNICAL DETAILS AND PRICES

To run the software you need either an Apple Macintosh (minimum 512 K Enhanced), or a PC, eg an IBM AT, running Microsoft Windows 2.01 or above (a hard disk and a mouse are strongly recommended). The demonstration disk for the PC also requires MS-Windows.

Each module costs US$150/£95 (plus VAT in UK only) – less 20% discount for all academic purchasers. You can save an extra 10% by purchasing all four modules together, at US$540/£342 (less 20% discount for academic purchasers and plus VAT in UK).

Microsoft is a trademark of Microsoft Corp, IBM of International Business Machines Corp and Macintosh of Apple Computer, Inc.

Repligen IPA-300: The Protein A that can cut development time

Repligen provides ultrapure and immobilized rProtein A with complete documentation on file with the FDA and full support from our experienced staff of regulatory affairs specialists. This means that you lose less time substantiating your materials and complete your IND submission faster. Plus IPA-300 guarantees high binding and virtually no leakage to the toughest specifications in the industry. So for the consistent purity you need for single pass purification of therapeutic grade monoclonal antibodies, specify Repligen's IPA-300. Whether it's 2 milliliters or 2 liters, we'll ship in one business day. Cut through the paperwork. Call us today.*

GRAPH

Much easier to use than Sigma-Plot, and far less expensive!

For $79 MicroMath's GRAPH program provides you with most of the plotting features found in much more expensive packages. Included are several built-in empirical curve generating routines and data may be transformed using a variety of operators. The program can be configured at run-time for output to PostScript or HPGL devices, or to a wide variety of dot matrix printers. Call our toll free order line for a FREE copy of our full featured GRAPH demo program.

If you need full fledged nonlinear curve fitting in addition to simple data plotting, then MINSQ is the solution. For $179 MINSQ offers tremendous flexibility for fitting model equations entered at the keyboard or read from a file. Call for a FREE copy of our catalog - it includes detailed technical application notes regarding MINSQ and our other scientific software packages.

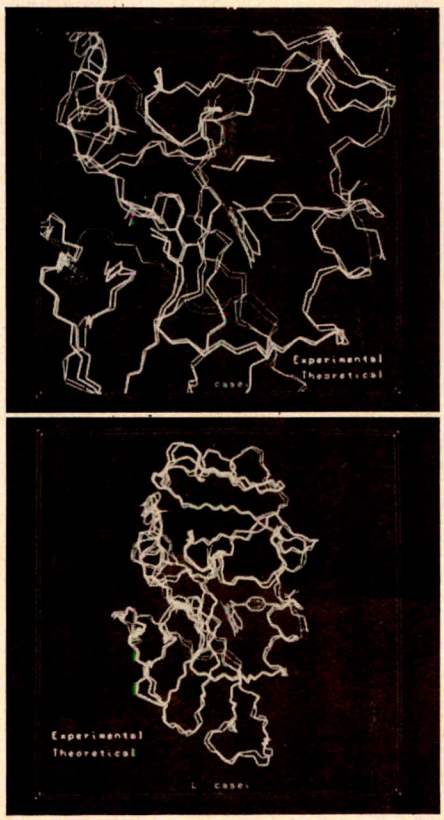
Researchers can add geometric constraints to a query using MACCS-3 D from Molecular Design.

models and model-related data, including data specific to atoms and atom pairs. Developed by a consortium of nine chemical and pharmaceutical companies, the models in MACCS-3D are standard MACCS II structures for which additional 3-D information is stored, including Cartesian coordinates, partial atomic charges and MM2 energy. The software allows exact-match, substructure, and submodel



Conformational analyses can be performed using the system's 3-D tools.

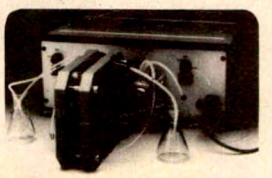
searching of 3-D models, where geometric constraints on angles, dihedral angles and exclusion spheres can either be set by the user or left at MACCS-3D's default. Molecular Design emphasizes the application of MACCS-3D in identifying candidate drugs based on geometric properties. The software will be available in November, says the company.

A second generation version of TOPFRAG — Derwent Publications' chemical fragment coding system — which allows the user to **develop search strategies for generic structures** or groups/families of chemical compounds is being developed by Hampden Data Services Ltd (*Reader Service No. 105*). Generic TOPFRAG provides automatic generation of fragmentation codes from graphic search queries of specific compounds, and produces a search strategy that aids in the search of the World Patents Index files on three major online hosts. Other features include improved drawing capabilities made possible by Hampden's Psidom industry standard Chemical Structure Drawing Interface, a wider range of PCs, printers, and mice. Generic TOPFRAG is currently undergoing β testing and is scheduled for release at the end of the year, says the company, who can be seen in booth 425.

Chemical Design, Inc. and ORAC Ltd have joined forces to produce KERNIX — a computerized system for **chemical information management**, which is due for release later this year (*Reader Service No. 106*). Based on compound document architecture (CDA) and run under DECwindows, KERNIX is designed for the management and exchange of information between databases, computerized documents, modelling systems and other information sources. CDA uses the file format called Digital Document Interchange Format to allow files with values from databases, text, digitized images and graphics to be created, stored and exchanged over a range of devices and operating environments. Chemical Design says the use of DECwindows provides an easy-to-use windowing interface with pull-down and pop-up menus, while taking full advantage of a networking facility. Chemical Design will be in booth 322.

BIOGRAF backgrounder is the new **molecular modelling and simulation software** package from BioDesign Inc., which allows researchers to evaluate the structure, properties and behaviour of molecules at the atomic level (*Reader Service No. 107*). The software uses molecular dynamics and mechanics algorithms and conformational searches to allow researches to visualize and model molecules, examine their active binding sites in 3D, and perform energy calculations on the model. BIOGRAF offers support for many classes of compounds and has applications in protein research, drug design and interaction studies, and DNA modelling, says the company. Central to the accuracy of the simulation are the force fields which are based on theoretical calculations and predictions. BIOGRAF provides its own proprietary force field called Drieding but can interface with MM2, AMBER and CHARMM force fields. The software will run on selected leading computers, graphics terminals and workstations and prices range from $30,000 to $150,000 (US). BioDesign will be in booth 122.

Two views of dihydrofolate reductase with methotrexate bound, simulated using BioDesign's BIOGRAF software.



Data handling

Hewlett-Packard Company, exhibiting in booth 203, will be launching HP LAB/UX — a **laboratory information management system** for the efficient organization of laboratory data (*Reader Service No. 108*). The system is based on proven LIMS software and the latest HP precision architecture computer systems. LAB/UX can be customized to suit user and laboratory needs, and can support up to 20 simultaneous users. LAB/UX can be expanded

LIPOSOMES
NEW
REPRODUCIBLE — HOMOGENEOUS — EXTREMELY RAPID

Our new LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized unilamellar liposomes. Liposome size is selectable between 25 and ca. 600 nm diameter. Sample volume is normally 5-10ml or up to 200ml if used in combination with an additional instrument. Lipid concentration can be up to 300 mg/ml.
BIANORM

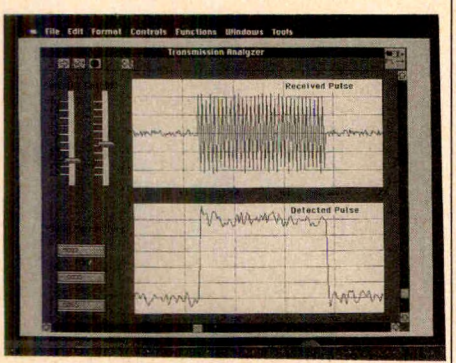
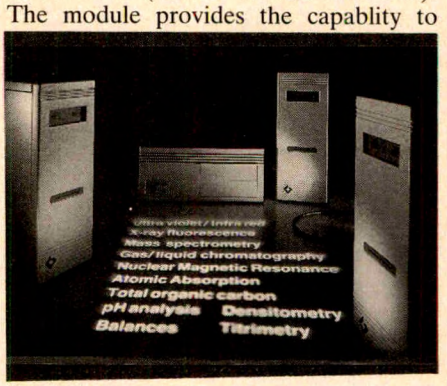
Reader Service No.45



and updated without the need for reprogramming or system shut-down, says the company. Special features include sample log-in, test scheduling, result entry and validation, reporting, storage, search and retrieval of results from the database, and laboratory resource scheduling. Using the report generators, users can customize their own reports, and integrate both text and graphics into the report. Audit Trail and Labquest programs for tracking data history and for the rapid search, sort and presentation of information in the database are supplied as standard. As part of HP's Unified Laboratory Strategy, LAB/UX can communicate with PCs, mini- and main-frame computers.

National Instruments will be highlighting, in booth 519, LabVIEW 2 — a **graphical programming language** that allows researchers to develop control and monitoring programs for laboratory automation, data aquisition and instrumentation (*Reader Service No. 109*). Designed to run on an Apple Macintosh II computer, the

Improved editing facilities are a feature of the Version 2 of LabVIEW from National Instruments.



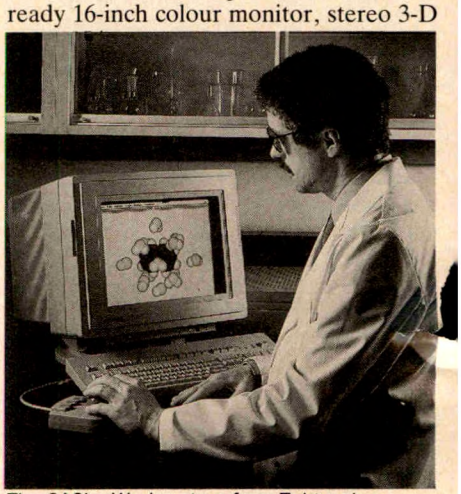
software allows the build-up of control programs from functional blocks called virtual instruments (VIs). The VIs can control analysis equipment, process data or display information and, says the company, can be combined in a heirarchy to produce complex application programs. An important feature of the $1,995 (US) LabVIEW 2 is the compiler, which con-

Data presentation with LabVIEW 2.

verts block diagrams into machine code, greatly increasing the execution speed, says the company. Improved editing features include wire-stretching and cut-and-paste facilities, colour data presentation, and an extended library of functions. LabVIEW 2's open architecture allows its programs to be interfaced with those written in conventional languages.

VG Laboratory Systems, exhibiting in booth 420, has a new **data aquisition device** — the VG Instrument Server — which provides the hardware interface link between Data Manager and analytical instruments (*Reader Service No. 110*). The module provides the capablity to

The VG Instrument Server.



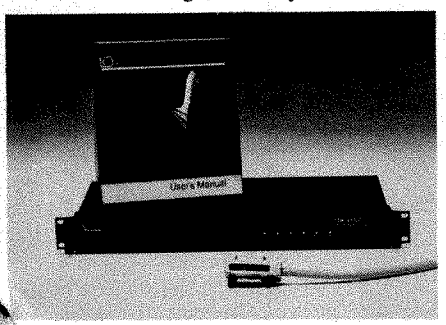
automatically collect test results for storage in the LIMS database, speeding up data entry and eliminating possible transcription errors, says the company. Either four or eight RS232 serial lines can be attached to one instrument server, which can then be connected either directly to a VAX or via Ethernet. The Instrument Server can connect to any instrument with serial, parallel, BCD, or analog interfaces. Other features include 1/2 MByte RAM, worksheets for instruments with autosamplers, selection of data from reports, non-stop data aquisition, barcode option, and hand-held data collection.

OMEGA 235 is the new **liquid chromatography software package** from Perkin-Elmer Nelson Systems for the aquisition and analysis of spectral data (*Reader Service No. 111*). Designed for use with OMEGA-2 or OMEGA-4 chromatography workstations integrated with the Perkin-Elmer LC-35 detector, the application software package provides automatic uploading from the detector after each chromatographic run. The chromatogram and spectral data can be displayed side-by-side on the same screen, stored on the system's hard disk, or printed on a GP-100 printer/plotter. The facility for multiple spectral overlays allows the user to identify peaks and confirm peak purity. When using OMEGA 235 software, all normal data handling functions of the workstation are maintained. The package comprises the OMEGA add-on LC application software and LC-235 spectral view program. Perkin-Elmer Nelson Systems will be exhibiting in booth 304.

In addition...

Designed to make conventional integrators obsolete in terms of performance and cost, the latest Peakmaster PC-based **chromatography data station** from Harley Systems Ltd can store raw and processed data on disc, allowing reintegrations to be performed without the need for reinjection (*Reader Service No. 112*). The £2,850 (UK) system comprises a Masterlink interface and the software to connect two chromatographs to an IBM PC or compatible: a further two channels can be added for £850 (UK). Other data analysis features include the facility for the enlargement of sections of chromatograms and the subtraction of one curve from another to highlight sample differences. The Peakmaster system provides control of integration parameters, including baseline incline, convolution, skim type and skim ratio, control of external devices such as fraction collectors, pumps and autosamplers, and numerical and graphical reprocessing of chromatograms. The system can be interfaced with most chromatography instruments and can function in a stand-alone form or can be networked.

Apple Macintosh Cx or IIx users can now upgrade their machine with the CAChe Worksystem — the **stereo 3-D molecular modelling system** — for less than $20,000 (US), says Tektronix, Inc. (*Reader Service No. 113*). The upgrade package includes an 88-K accelerator board, Trackball input device, stereo-ready 16-inch colour monitor, stereo 3-D



The CAChe Worksystem from Tektronix.

graphics card, graphics software, molecular editor software, manuals, system assembly, test and installation. The package incorporates MM2 force fields, conformational analysis, and extended Hückel for the quantum mechanical calculation of electronic properties. The CAChe Worksystem features a cut-and-paste facility for importing molecular structures into other Macintosh applications such as ChemDraw, Microsoft Word and Excel, and provides full colour graphics output support for slides, reports and documents.

Keithley Instruments Ltd has an IOtech DAC488 **digital-to-analog converter** with built-in waveform buffer that is available

in either a two- or four-channel version (*Reader Service No. 114*). The DAC488/4 four-channel version, has four analog outputs that can be programmed for range and output voltage. Each independent channel has three voltage ranges: ± 1 V, ± 5 V and ± 10 V. Outputs can be described in either volts or binary bits from the IEEE bus. Special features of the unit include an autorange feature that automatically switches to the range that provides the best resolution for the commanded voltage, and a synchronization

The DAC488: Keithley Instruments' digital-to-analog converter.

feature that allows all four channels of the digital output to be updated simultaneously. A 1024-point voltage waveform can be saved in non-volatile RAM for each output channel, which, says the company, allows the user to store a different waveform for each channel.

Map drawing

According to GeneSystems, Plasmid Artist is the first graphics program that produces publication-quality **plasmid diagrams** (*Reader Service No. 115*). Using a MacDraw-like user interface, pull-down menus and a mouse, users can draw linear or circular restriction map diagrams of recombinant DNA molecules containing, says GeneSystems, a virtually unlimited number of restriction sites and fragments. The 'Site' menu has over 60 common restriction enzyme names, but others can be added by the user. Plasmid Artist, costing about $395 (US), automatically keeps track of the map size and positions all restriction fragments and sites in their scaled positions. GeneSystems says, high-quality images can be printed on a PostScript printer. Alternatively, the image can be exported as an encapsulated PostScript file to page layout programs such as Page Maker and Cricket Draw for incorporation into reports and manuscripts.

CLONE 2 is the upgraded version of the CLONE Manager Program from Scientific & Educational Software for **constructing and drawing circular and linear restriction maps** of recombinant DNA molecules (*Reader Service No. 116*). Designed to run on an IBM PC/XT, AT, PS/2, CLONE 2 uses pull-down menus to create maps of presentation quality, says the company. Enzymes can be used to 'cut' molecules into fragments, which can then be ligated onto other DNA fragments. After ligation, the base positions of enzyme sites, genes and markers are automatically recalculated and the maps can be printed immediately. The program automatically determines the cohesive ends produced by each enzyme used, and uses this information to identify compatible ends. CLONE 2 contains a comprehensive list of restriction enzymes, however, the user may add to these if necessary. The program is supplied with a 50-page user manual: demo versions are available on request.

Handy helpers

Using only a few keystrokes, users can **convert units of measure** from one unit system to another with the S.I. Plus PC software program from Geocomp Corp. (*Reader Service No. 117*). Designed to run on IBM PCs or compatibles, S.I. Plus contains all the unit conversion factors commonly used by engineers and scientists, and over 70,000 different conversions can be performed in 80 classes of units, says Geocomp. The $79 (US) S.I. Plus can also be used as a memory-resident program, whereby the S.I. Plus menu can be accessed while running another program.

Version 4.2 of Get-A-Ref — DatAid, Inc.'s **reference handling software program** — is now available (*Reader Service No. 118*). Get-A-Ref is designed to run on IBM PC/XT/AT/386/PS computers or compatibles and features an Editor with context-sensitive help, an improved user interface, and a cut-and-paste facility for integrating citations into manuscripts. The software comes complete with its own database conversion utility, which allows users of databases such as Medline, BIOSIS, Chemical Abstracts, Excerpta Medica and IRIS to convert screen dumps of information into Get-A-Ref files. According to DatAid, the program can store up to 32,000 references in ASCII format, with up to 16,000 characters of text in each file. Searches can be conducted at a rate of 100,000 characters per second and without the need for user-defined keywords, says the company.

Mathematical problem solving is made easy with the Version 4.3 of Maple — an interactive **computer algebra system** for both symbolic and numerical computations — from Waterloo Maple Software (*Reader Service No. 119*). Designed for IBM PS/2 Models 70 and 80, and other 80386-based machines running PC-DOS or MS-DOS, the $1,100 (Cdn) Maple software has scientific, engineering, business and educational applications. The software uses standard mathematical notation for problem solving in an interactive environment, and can be used to solve equations and perform integrals at all levels. □

These notes are compiled by Diane Gershon from information provided by the manufacturers. To obtain additional information about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

Information skills still in demand

Richard Pearson

Employers may have to pay a high price for not taking the responsibility for training their own staff in information technology skills.

THE production and use of information technology (IT) continues to be a key factor in the growth of many economies. In the United Kingdom the market has been growing at around 15 per cent a year, and is now worth more than £20,000 million. But since the early 1980s, there has been concern that shortages of suitably qualified staff have been constraining the development of both the IT industry and the use of IT throughout the economy.

The fastest rates of IT employment growth in the late 1980s have been in the IT consultancy, software and services companies. In electronics, employment has been recovering after the slump of 1986–87. Among the users, growth has been variable, but has been strongest in the service sector with industry still lagging behind[1]. In 1988, there were more than 240,000 professional IT staff employed in the United Kingdom, an increase of about 5 per cent since 1987, and 20 per cent since 1985. Total employment is now divided almost equally between the electronics and IT services sectors and users of IT in industry and the service sector; this represents a shift towards the user sector.

The recruitment of experienced staff continues to be the principal way in which most employers fill vacancies for professional IT staff. This, however, simply involves a reallocation of existing staff between organizations as employers chase staff with two or more years' experience of a particular technology or application. New graduates remain the main source of new entrants to the stock of professional IT staff, with demand continuing to rise throughout the 1980s.

In 1988, half the graduates recruited for IT work had electronics or computer studies degrees, while most of the remainder were from numerate scientific or technical disciplines. Electronics graduates went chiefly to the electronics sector. Computer science graduates were recruited to all sectors although recruiters still have mixed views about the quality and relevance of such graduates. Graduates from non-IT disciplines were principally recruited for computing work, few being taken into electronics areas. Very few graduates from non-numerate disciplines take up computing work. There remains only a small demand for postgraduate qualifications in IT, principally for research work in the electronics sector and higher education.

The output of IT graduates increased rapidly in the 1980s, and most electronics and computer science graduates moved straight into relevant employment. The downturn in female students both applying for and entering university IT degree courses has been of particular concern, although some improvement is visible in the 1988 figures. The fall-off in interest from women has been particularly marked in computer studies; it is also reflected in the difficulties of many employers in their attempts to increase the recruitment of women to IT posts.

Recruitment difficulties continue across all professional IT occupations and sectors; the improvement shown in 1987 has not continued into 1988. Problems have been most acute for employers seeking experienced computing staff and software engineers and project managers/leaders, and where very specific technical expertise is required or combinations of technical/commercial/personal skills. Problems in recruting new graduates seem to have been least accute in South-East England.

An increasing but still small number of employers are responding to recruitment difficulties by improving career development, retraining and deployment of staff; seeking to control wastage; increasing internal pay flexibility; reorganizing and redesigning IT work; and in some cases relocating the work to easier provincial labour markets. But progress remains slow outside the public and financial sectors where there is a history of internal staff development and retraining and salary increases remain the primary response for most employers.

Looking to the future, continued growth is expected in the IT market and in employers' needs for professional IT staff to service both business growth and the growing use of IT in new areas. Considerable uncertainty exists, however, about the rate of market growth, and the effects on employment patterns of mergers and acquisitions, European markets and competition and the contracting out of IT work.

Few employers have a developed form of manpower planning. Most plan employment and recruitment levels over no more than 12–18 months and are therefore unable to forecast future IT employment levels with any precision.

What is clear, however, is that the labour market for professional IT staff will become increasingly compartmentalized, with the balance of supply and demand varying between sectors, locations, occupations and types of experience. There is expected to be a continuing growth in the demand for software and computing skills and applications experience, but little growth in the case of hardware skills. With the growing 'user-friendliness' and spread of IT, there will be a need for more 'hybrid' staff with both IT and application skills. Occupational boundaries will become increasingly blurred. The main growth occupations are likely to be based on communication and networks, and IT consultants/business analysts because of the greater integration of IT into the business. Demand for analysts/programmers and computing is also expected to continue to grow. Overall demand is likely to grow at under 5 per cent per annum, assuming economic growth continues, representing a slowdown on recent years.

Graduates will continue to be the main source of new entrants to IT jobs and graduate intakes are expected to increase. While the supply of IT graduates is expected to continue to rise into the early 1990s, the increased demand from recruiters in general will put pressure on recruiters seeking to fill IT jobs from a wider range of subjects than just IT. In the mid-1990s, the output of graduates is expected to stop growing, because of the demographic downturn[2]. As demand is expected to continue to rise, there will be increasing competition from IT and other employers for graduates from IT and other numerate disciplines.

The outlook is for a continuation of the tight labour market for IT skilled staff. Employers will continue to face difficulties recruiting experienced professional IT staff unless they give more attention to the use of in-company resources for retraining/conversion, to non-traditional recruitment sources and to greater flexibility in working arrangements. A start has been made by a few employers, but there is need for more innovative practices both within the IT industry and beyond in the expanding user sector. □

Richard Pearson is at the Institute of Manpower Studies, Mantell Building, University of Sussex, Brighton, Sussex, BN1 9RF, UK.

THE PERFECT BIND

When did Nature cover Science in Switzerland?

Where are the latest research results about AIDS?

What's the latest development in superconductivity?

Have you noticed that you never manage to lay your hands on that issue of Nature when you need it most!

For a very reasonable cost, why don't you save time and effort by investing in a set of smart and durable Nature binders.

	Single binder	Set of 4	
UK	£5.25	£16.00	Prices include
Rest of World	£7.75	£22.00	postage and packing

Never again will you be at a loss for that vital information. Each binder holds approximately 16 issues and makes sure that key knowledge is kept at your fingertips.

Complete the order form and in no time your copies of Nature can be kept in order.

Please send me_____Nature binders

☐ I enclose a cheque for £_____ made payable to Nature

☐ Please charge my credit card for £_____
☐ Visa ☐ AMEX ☐ Access
☐ Diners Club

Peptide and Amino Acid Transport Mechanisms in the Central Nervous System

Edited by L Rakic, Professor of Neurobiology and Biochemistry, Belgrade Clinical Centre; David J Begley, Lecturer, Department of Physiology, King's College London; Hugh Davson, Professor of Physiology, St Thomas Hospital, London and Berislav, Associate Professor, Belgrade University Institute of Medical Physiology

The way in which the brain regulates its internal environment separately and distinctly from the rest of the body has long generated intense interest and debate. Today, advances are being made at an ever accelerating rate. This volume addresses itself to regulation, within the brain extracelluar fluid, of peptide and amino acid levels, particulary those which are known or putative neurotransmitters and neuromodulators. Particular attention is also devoted to the way in which peptides may penetrate the blood-brain barrier or alter its permeability to other solutes. This volume is of vital relevance to anyone studying central nervous system disease, especially the fundamental problem of designing drugs and agents which will penetrate the blood-brain barrier and excert central nervous actions. The relevance to mental health and disease is also unquestioned.

Contents: Introduction; H.Davson / Neuropeptide Transport Mechanisms in the Central Nervous System; B.V. Zlokovic et al / Peptides and the Blood-Brain Barrier: Penetration and Modulating Influences; W.D. Banks et al / Structural Aspects of the Blood-Brain and Blood-CFS Barriers with Respect to Peptides and Proteins; K. Mollgard / Proteins in CFS of the Developing Brain; N.R. Saunders & K. Dziegiewska / Cyclic Necleotide Mediated Regulation of Albumin Transport in Brain Microvessels; F. Joo / Peptides and Cerebral Microvessels; M. Spatz / Transport and Barrier Systems of the Cerebral Microvasculature: Enzymatic Aspects; B.M. Duricic & B.B. Mrsulja / Transport of Insulin at the Blood-Brain and Blood-CFS Barriers; L.K. Squires & D.J. Begley / Insulin as a Regulatory Peptide in the CNS; D.G. Baskin et al / Experimental Psychosis and Transport of Amino Acids and Peptides Across the Blood-Brain Barrier; L.K. Rakic et al / Transport of Enkephalins from the Cerebrospinal Fluid of the Rabbit; D.J. Begley / Control of Opioid Peptide Levels by Peptidases in the CNS; L.B. Hersh / The Effect of Cyclic AMP and Adenylate Activators on CSF Production; S. Hyman et al / Peptide Receptors of the Cerebral Capillary Endothelium and the Transport of Amino Acids Across the Blood-Brain Barrier; A. Ermisch et al / The Effects of Vasopressin and Related Peptides on Tolerance to Ethanol; P. Hoffman / Sleep Effects of Delta-Sleep Inducing Peptide DSIP; V. Susic / Techniques for Investigating the Blood-Brain Barrier in Non-Mammalian Species; J. Abbott & B.V. Zlokovic / Amino Acid and Prolactin Transport into CNS; A. Lorenzo / Amino Acid Uptake in Synaptosomal Preparations; A. Lajtha & E.A. Debler / Exchange Diffusion of Neutral Amino Acids from Blood to Brain; A. Gjedde / Kinetic Analysis of Blood-Brain Barrier Transport with References to Amino Acids; J. Hargreaves & V. Cunningham / The Mechamism of Amino Acid Transport Across the Choroid Plexus; M.B. Segal & B.V. Zlokovic / A Comparative View of Amino Acid Transport at the Blood-Brain and Placental Barriers; D.L. Yudilevich & C.P.D. Wheeler / Discussion and Conclusions / Index

Peripheral Actions of Dopamine

Edited By Christopher Bell, Department of Physiology, University of Melbourne, Australia and Barry McGrath, Monash University Medical School, Melbourne, Australia

This book reviews the current state of research in three main areas concernng the actions and significance of dopamine in the periphery: the source and effects of endogenous dopamine; the classification and distribution of, and the effects of activating, various populations of peripheral dopamine; and the therapeutic significance of dopamine receptor activation and renal disease.

Contents: Sources of Circulating Dopamine: A Personal View; J-L. Cuche / Dopamine Storage in Sympathetic Nerves; P. Soares-Da Silva / Neurochemistry of Dopaminergic Nerves; C. Bell, M. Ferguson & T. Petrovic / Release of Dopamine from the Kidney in vivo; P. Hjemdahl, T. Bradley & B. Tidgren / Dopamine and Renal Failure; W. Adam / Dopamine and Hypertension; M. Yoshimura & H. Takahashi / The Vascular (DA1) Dopamine Receptor; J.D. Kohli & L.I. Goldberg / Renal Dopamine Receptors; R.A. Felder, C.C. Felder, G.M. Eisner & P.A. Jose / Gastrointestinal Dopamine Receptors; R.A. Lefebvre / Neuronal Dopomine Receptors; M.F. Lokhandwala & M.L. Defeo / Drug Design for Cardiovascular Therapeutics: Activation of DA1 Receptors; B.A. Berkowitz / Use of Dopamine Agonists in Cardivascular Disease; B.P. McGrath, N. Sano & B.F. Jover / Modified Dopamine Agonists; R.D. Hoskins, R.A. Brown, R.A. Foulds, F. Ince, S. O'Connor & G.W. Smith / Dopamine Pro-Drugs; M.R. Lee / Index

Pharmacology and Functional Regulation of Dopaminergic Neurons

Edited by Philip M Beart, Geoffrey N Woodruff and David Jackson

This is the proceedings of a Satellite Symposium of the 9th IUPHAR Congress in Sydney in 1987 entitled Dopamine 87. It covers all aspects of research into dopamine systems and their regulation.

Contents: All 66 Papers presented at the Satallite Symposium of the 9th IUPHAR Congress

1988 424pp 234x156mm Hardback £45.00 0-333-45944-X

New Concepts in Depression

Pierre Fabre Monograph Series, Volume 2

Edited by M. Briley, Pierre Fabre Medicament, Castres, France and G. Fillion, Head of Neuroimmunoendocrinology, Pasteur Institute, Paris

Depression is increasingly seen as an important debilitating neurological condition. This book brings together a timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression. In addition, a number of chapters concentrate on clinical or physiological phenomena associated with depression. The general attitude of the book is one of openness to new ideas several of which are presented here for the first time.

Contents: The Contributors / Preface to the Series / Preface / Biochemical Mechanisms in Depression / 5-HT and Depression / Physiological Correlates in Depression / From Experimental Models to Man / Clinical Pharmacology of Depression and Associated Phenomena

1988 392pp 234x156mm Hardback £45.00 0-333-44133-8

You can order any of these titles from your bookseller. Alternatively, send your order to: ***Richard Gedye, Macmillan Press Ltd, Houndmills, Basingstoke, RG21 2XS, UK.*** *Please add £1.00 to cover post & packing & allow 28 days for delivery.*

THE FELS INSTITUTE FOR CANCER RESEARCH AND MOLECULAR BIOLOGY

POSITIONS AVAILABLE

FACULTY-POSTDOCTORAL MOLECULAR BIOLOGISTS

Tenure-track positions. All areas of molecular biology and genetics are of interest. Some preference will be given to developmental molecular biology and research on transgenic animals. Send curriculum vitae, a brief statement of research plans and request that three letters of recommendation be sent to the address below.

PROTEIN CHEMISTS

Tenure track positions. Send curriculum vitae, a brief statement of research plans and request that three letters of recommendation be sent to the address below.

POSTDOCTORAL POSITIONS

Postdoctoral positions are available in the areas of molecular biology and genetics, gene mapping, cell biology, biochemistry and carcinogenesis. Active programs include oncogenes, genetic alterations in cancer formation, gene mapping, genes in growth control, DNA repair mechanisms, receptors and cellular transduction systems. Send curriculum vitae, a short statement on training interests, if known, and request that three letters of recommendation be sent to the address below.

Send information requested above to: **Dr. Gerald Litwack, Deputy Director, The Fels Institute for Cancer Research and Molecular Biology, TEMPLE UNIVERSITY SCHOOL OF MEDICINE, 3420 North Broad Street, Philadelphia, PA 19140.**

An Equal Opportunity Employer. (NW4333)A

The University of Queensland

Equal Opportunity in Employment is University Policy

Lecturer in Pharmacology
(Fixed Term)
Physiology & Pharmacology Department
(Re-advertised)

The Department is seeking to recruit a pharmacologist with active research interests which complement the current departmental activities in pulmonary pharmacology, sensory and autonomic neuroscience, molecular endocrinology and reproductive biology, immunology and toxicology. Some departmental support will available, but the applicant will be expected to have the ability to attract outside funding for his/her research. Interaction with other research programs in the Department will be encouraged.

The appointment will be expected to participate in the Department's teaching programs in Pharmacology to Medicine, Veterinary Science, Dentistry, Pharmacy and Science students. Appointment will be for 5 years with salary in the range of $31,258–$40,621pa.

Further information may be obtained from Professor McLachlan (07) 377 3133.

Closing Date: October 27, 1989. **Ref. No:** 41989.

Application forms and further details concerning method of application are available from the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London, WC1H OPF. (W6550)A

RESEARCH FELLOW

A$31,525–A$38,567 per annum

DIVISION OF PLANT INDUSTRY
CANBERRA A.C.T.
AUSTRALIA

THE DIVISION: The CSIRO Division of Plant Industry conducts research on problems fundamental to plant biology and agricultural production. Prominent among the research activities are programs concerned with gene transfer and expression, cell culture, herbicide biology and synthesis, photosynthetic processes and biological nitrogen fixation. The prime objective of this research is to develop the capacity for the genetic manipulation of crop plants to improve productivity.

THE JOB: The Rockefeller Foundation is funding a program to provide resistance against ragged stunt virus infection in rice. The appointee will undertake research into this problem. The research will involve the synthesis of gene constructions based on viral genome components which are to be cloned during the research program.

THE PERSON: Applicants should have a PhD or equivalent qualifications with demonstrated research achievement in molecular biology or virology. Sound communication skills and the ability to clone and sequence nucleic acids are essential.

CONDITIONS: Appointment will be for a term of 3 years with Australian Government Superannuation benefits available.

MORE INFORMATION: Prospective applicants are invited to telephone Dr P. Waterhouse 61 62 46 5463 or Dr W. Gerlach 61 62 46 5204, for further information. A copy of the detailed duty statement and selection criteria may be obtained by telephoning 61 62 46 5206.

APPLICATIONS: Applications should be submitted by **four weeks after date of publication** and quote reference number **N8915**. They should be framed against the selection criteria, and state relevant personal particulars including details of qualifications and experience. Applicants should give details of at least two referees, and address their applications to:

The Chief
CSIRO
Division of Plant Industry
GPO Box 1600
CANBERRA ACT 2601
AUSTRALIA

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

CSIRO AUSTRALIA

AB1-PLN 89/15

MEDICAL RESEARCH COUNCIL
BRAIN METABOLISM UNIT — EDINBURGH
MOLECULAR/CELLULAR NEUROBIOLOGY

Applications are invited for the position of non-clinical short-term scientist for a term of 3 years with a possible extension to 5 years. The successful candidate will join a group of 5 scientists investigating the regulation of neuropeptide gene expression in the nervous system, with special emphasis on the role of nerve growth factor. Previous experience of molecular biological techniques and/or neuronal cell culture would be an advantage. The person appointed should hold a PhD or equivalent.

Remuneration will be at an appropriate point on the MRC non-clinical scientific scale Grade 2 (£10,458-£15,372). Informal enquiries may be directed to Dr A J Harmar or Dr K Chapman (Tel 031-447 2011 ext 4530).

Further information may be obtained from **Mrs Janet Dalitz, Administrator, MRC Brain Metabolism Unit, University Department of Pharmacology, 1 George Square, Edinburgh EH8 9JZ (Tel 031-667 1011 ext 2311)** to whom applications, including a curriculum vitae and the names of three professional referees, should be sent. Closing date for applications is 6 November 1989.

The MRC is an Equal Opportunity Employer. (1767)A

MRC

UNIVERSITY OF CAPE TOWN

Electron Microscope Unit:

Director (Associate Professor Level)

Applications are invited from suitably qualified persons with wide experience in the use of transmission and scanning electron microscopes in the biological and physical sciences, and in the application of electron microscopy for research.

Preference will be given to applicants with leadership and managerial skills who are prepared to negotiate for funding with the University authorities and industry for the purchase of equipment for the EMU, and whose research record would qualify them for financial support from an appropriate funding agency. Nevertheless, all suitably qualified candidates are encouraged to apply.

A negotiable salary package includes attractive staff benefits such as medical aid, a pension scheme and a housing subsidy in certain circumstances. Further details concerning remuneration will be sent to applicants on request. In the case of academic appointment, the post will be at Associate Professor level. The University reserves the right to make an appointment at any other level, or on other than academic conditions of service.

The selection committee for this post will meet soon after 30 November 1989, but the post will remain open until filled. However, the University reserves the right to make no appointment or to appoint a person other than one of the applicants.

Dept of Microbiology:

Senior Lecturer / Lecturer

Applications are invited for this post, for appointment as soon as possible.

An interest and experience in bacterial physiology and biochemistry, or anaerobic bacteriology, microbial genetics or recombinant DNA technology will be a strong recommendation.

A negotiable salary package includes attractive staff benefits such as medical aid, a pension scheme and a housing subsidy in certain circumstances. Further details concerning remuneration will be sent to applicants on request.

The post may be filled on a permanent basis or on a three year fixed-period basis, whereafter it may be renewed or converted to a permanent post.

Applicants should state the level of post for which they are applying and whether they wish to be considered for a temporary or permanent appointment. Applicants for the Senior Lectureship should also indicate whether they would be prepared to be considered for a Lectureship.

The closing date for applications is 30 November 1989.

Applicants should submit a full curriculum vitae (stating the post for which they are applying) and the names and addresses of three referees, to the Appointments Officer (Ref: NB), University of Cape Town, Rondebosch 7700, Republic of South Africa (telephone: (21) 650-2192; fax: (21) 650-2138). Further information may be obtained from the above, or from the Secretary, SA Universities Office, 2nd Floor, 16 Charles II Street, London SW1Y 4QU.

The policy and practice of the University of Cape Town is to oppose discrimination on grounds of gender, race or creed in any sphere of university life.

(W6546)A C66512/956-O

THE UNIVERSITY OF BIRMINGHAM
SCHOOL OF EARTH SCIENCES
RESEARCH ASSOCIATE IN GEOPHYSICS

A computer literate geophysicist with interests in shallow (resistivity) techniques is required to work on a major NERC funded project to set up a national database of resistivity soundings and develop associated software. The preferred applicant should have an M.Sc. in geophysics and proven computing ability. The post is at Research Associate level, £9,816-£12,381 (plus superannuation) according to experience and qualifications.

The post is initially offered for a six-month period, although funding for a two-year project has been provisionally agreed.

Informal enquiries may be made to Dr R.D. Barker on 021-414-6158. Application forms and further details are available from **The Staff Office, The University of Birmingham, Edgbaston, Birmingham B15 2TT, telephone 021-414-6483** (24-hour answerphone, please quote Ref ES/2160) to whom they should be returned by 20th October.

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE seeks a NEWS REPORTER

Essential qualifications:
* A good science education
* Capacity to write fluently

Other relevant qualifications:
* Experience as a journalist
* A second European language
* First-hand knowledge of research

Salary by negotiation. London-based, but the successful applicant must be prepared to travel. Apply with full *curriculum vitae* and names of two referees to the **Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF** as soon as possible. (1780)A

AMERICAN CANCER SOCIETY
BASIC CANCER RESEARCH EMINENT SCHOLAR CHAIR
UNIVERSITY OF FLORIDA
(Edward R. Koger Professorship)

Applications are invited for candidates to fill a faculty professorship in Basic Cancer Research, funded through an Eminent Scholar Chair sponsored by the American Cancer Society. The candidate should have demonstrated a strong commitment to academic medicine. Candidates must hold an Ph.D., M.D., or both, and have an accomplished research record in the investigation of fundamental processes of neoplasia. A highly interactive individual would be desirable to take advantage of the research collegiality available at the University of Florida. The scholar could be appointed in a basic science department or jointly with a clinical department. Salary is negotiable and will be based on credentials. Deadline for receipt of applications is January 15, 1990.

Candidates for this position should be nominated or they should submit a letter of application stating teaching and research goals, and include a curriculum vitae and at least three names of reference to **Edward M. Copeland, III, M.D., Chairman of Professorship Search Committee, Department of Surgery, Box J-286, JHMHC, Gainesville, FL 32610.** (NW4319)A

IMPERIAL COLLEGE OF SCIENCE, TECHNOLOGY & MEDICINE
University of London

LECTURESHIP IN ORGANIC CHEMISTRY

Applicants will be expected to have a doctorate and some postdoctoral experience. Salary will be within Lecturer A scale (£12,108-£17,022) or Lecturer B scale (£17,664-£22,119) inclusive of London Allowance.

Applications (including curriculum vitae, list of publications and names of two referees) and requests for further details to **Professor C W Rees FRS, Department of Chemistry, Imperial College, London SW7 2AY.**

Closing date: 31st October 1989. (1739)A

UNIVERSITY OF CAMBRIDGE
UNIVERSITY LECTURESHIP IN PETROLOGY

Applications are invited for a University Lectureship or Assistant Lectureship in any area of petrology. Salary scale £14,170-£21,850, or £11,088-£15,370.

Applications, with c.v. (10 copies) and names of three referees to **The Administrator, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ** by 30 November, 1989. (1777)A

A rewarding career with Glaxo

Eine lohndende karriere mit Glaxo

Een veelbelovende carrière bij Glaxo

Mass Spectroscopist

Bioanalytical Unit, Ware, England

The Mass Spectrometry group at Ware has an important role in the development of new medicines and we are expanding this section to meet the continuing increase in sample numbers.

We are involved in the identification of metabolites, drug degradation products and the development of bioanalytical assays. We have four mass spectrometers, incorporating state-of-the-art techniques, one of which is a recently installed triple quadrupole. All of which have helped us to establish an excellent reputation for qualitative and quantitative mass spectrometry.

We are now seeking an enthusiastic chemistry graduate to contribute to the solution of analytical problems and to the development of new techniques. You should hold a good degree in Chemistry coupled with one to two years' experience of operating a mass spectrometer. Experience in interpreting mass spectra is essential.

Applications are positively encouraged from candidates currently working in Europe.

In return, you can expect to receive a highly competitive salary package which includes guaranteed bonus and site allowance. Benefits include 25 days' holiday, flexible working hours, sports and social facilities and subsidised staff restaurant. A generous relocation package is available where appropriate.

To find out more, please telephone for an application form or send full career details to Sue Wilson, Glaxo Group Research Limited, Ware, Hertfordshire SG12 0DP, England. Tel: (0920) 469469, ext. 2732.

Glaxo Group Research

(1781)A

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND

ANATOMICAL SOCIETY RESEARCH STUDENTSHIPS

Applications are invited from prospective supervisors in Departments of Anatomical Sciences in the U.K. and Ireland for Research Studentships tenable in the Anatomical Sciences. These are tenable for a period of up to three years commencing in October 1990. Students nominated by Departments must be graduates of British or Irish Universities and will be expected to register for a higher degree. The stipend will be commensurate with basic Research Council rates.

ANATOMICAL SOCIETY SENIOR VISITING FELLOWSHIP

Applications are invited from senior Overseas Scientists with established reputations in the Anatomical Sciences, for one Fellowship tenable for a period of less than a year in a Department of Anatomical Sciences in the U.K. or Ireland. Applicants must have arranged sponsorship in the Department in which they intend to work. Some assistance towards travel and subsistence will be provided.

Further particulars should be obtained before application from the Honorary Secretary, Dr. Ian Whitmore, Department of Cell and Structural Biology, Stopford Building, University of Manchester, Oxford Road, Manchester, M13 9PT, to whom applications should be sent by 20th December, 1989.

(1733)A

THE UNIVERSITY OF SHEFFIELD
Department of Computer Science
SYLK Project: Combining Knowledge and Statistics in Speech Recognition

Research Associateship

The above post is available for research on a collaborative project involving the Department of Computer Science at Sheffield University and the Department of Linguistics & Phonetics at Leeds University funded by the Information Engineering Advanced Technology Programme.

The aim is to develop a speech recognition 'front-end' which attempts to answer the question 'Given an organised description of the acoustic evidence that seems to belong to the same syllable, what could the syllable be? The work develops from Alvey-funded projects on statistically-based broad phonetic classification (at Leeds) and object-based fine phonetic distinctions (at Sheffield).

Candidates should have research experience in Speech Technology, Phonetics, Statistics, Applied Mathematics, Computer Science, Machine Perception or a similar field.

Salary on the R/A IA scale or possibly on R/A IB. Informal enquiries to Dr P D Green (0742-768555 ext 5578). Further particulars from the **Director of Personnel Services, The University, Sheffield S10 2TN,** to whom applications, including a CV and the names and addresses of two referees should be sent by 31 October 1989. Please quote reference R940/G.

An Equal Opportunity Employer (1756)A

Postdoctoral Positions in Molecular Genetics

Applications are invited for two postdoctoral positions in the Molecular Genetics Group of Ciba-Geigy Ltd, Basle, for a period of up to three years. Successful candidates would join established research teams and participate in the following projects: (1) Structure/function analysis of peptide receptors in mammalian tissues as a basis for drug design, and (2) Genetic manipulation of antibody structure and its therapeutic applications. For both posts candidates should have a PhD with 0-3 years post-doctoral experience with sound training/expertise in recombinant DNA technology and an interest in protein engineering problems. For the second of these posts some experience with mammalian cell culture and/or immunological methods may be an advantage.

Ciba-Geigy is a major pharmaceutical company with an active interest and commitment to molecular biology. The Molecular Genetics Section is located in the Company's main research facility situated in Basle, Switzerland.

Applications, including a curriculum vitae, a summary of relevant research background and the names of two referees should be sent under ref. "Cell 2603" to Mr. H. Schmid, CIBA-GEIGY Limited, Personnel Department, P.O. Box, 4002 Basle, Switzerland.

(W6545)A

CIBA–GEIGY

University of Southampton

Institute of Biomolecular Science

Postdoctoral Research Assistant

Applications are invited for a PD to work in the field of biolo NMR. A VXR500 spectrometer been installed recently and supp a number of projects including con formational studies of antigenic peptides and structural studies of mutant enzymes. The successful applicant will assist in this work and develop new NMR experiments for biological applications. Experience of high resolution NMR is essential.

The appointment is available immediately and will be for one year in the first instance with a salary on the RA1A scale in the range £10,458–12,381.

Applications with a full CV and the names of two referees, or requests for further information, should be sent as soon as possible to **Dr. David Turner, Department of Chemistry, The University, Southampton SO 5NH, Tel: (0703) 593330.** Please quote reference no. 797JAD/nvs.

(1745)A

POSTDOCTORAL POSITION

available immediately to work on mitochondrial ATP synthase and structure function of its coupling factor B. A Ph.D. in biochemistry with training in enzymology and/or protein chemistry is needed. Send c.v. and 3 letters of reference to: **D.R. Sanadi, Dept. of Cell Phys., Boston Biomedical Research Institute, 20 Staniford St., Boston, Mass. 02114.** (EEO/AAE).

(NW4331)A

THE UNIVERSITY OF SHEFFIELD

Robert Hill Institute and
Department of Animal and Plant Sciences

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for the above post tenable from 1 January 1990 for three years to study the effects of viral infection on carbon partitioning in leaves. The work is funded by the AFRC through a Linked Research Group between the University of Sheffield and the AFRC Institute of Plant Science Research, Norwich. The work will involve measurements of gas-exchange, enzymes and metabolites in virus-infected cucumber and cowpea. Approximately one-third of the work will be done in Norwich.

Salary on Research & Analogous Grade IA, points 1 or 2.

Applications, including a curriculum vitae and the names/addresses of three referees, to **Dr R C Leegood, Department of Animal and Plant Sciences, The University, Sheffield S10 2TN.** Ref. MAP 198/G.

Of Guy's and St Thomas's Hospitals

Guy's Campus — close to London Bridge Stations

LABORATORY SCIENTIFIC OFFICER

required to work on an MRC project on HLA and autoimmune disease, involving molecular genetic studies.

The post would be suitable for someone with a good BSc in immunology, biochemistry or related subject, who may wish to go on to register for PhD.

Salary in the range of £7,605-£8,682 pa inc. depending on qualifications and experience.

For further information please contact Dr Steven Sacks on 01-955 4161. To apply, please send two copies of your CV to; **The Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH,** quoting reference no. G/CSL/383a. (1766)A

UNIVERSITY COLLEGE LONDON
DEPARTMENT OF ANATOMY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from nationals of the European Community for a postdoctoral position funded by ESPRIT. The work involves tracing specialised pathways in the primate visual cortex and studying their functional characteristics. Candidates should have or wish to acquire experience of modern anatomical and physiological techniques and computer reconstructions. Salary is £13,900.

Applications, with CV and the names of two referees, to **Professor S. Zeki, Anatomy Department, University College, London WC1E 6BT. Telephone 01-380 7187.** *Equal Opportunities Employer.* (1736)A

POSTDOCTORAL POSITION

to investigate mechanisms involved in adaptation of pituitary cells to increases in cytosolic Ca^{2+}, with emphasis on identifying the proteins involved. The position is available 1 January 1990. Send curriculum vitae, a summary of research experience, and the names and addresses of three references to: **Priscilla S. Dannies, Ph.D., Department of Pharmacology, Yale University School of Medicine, 333 Cedar Street, New Haven, CT 06510.** (NW4338)A

POSTDOCTORAL POSITION

A NIH grant funded postdoctoral position is available to join studies of the transcription, 3′ processing, RNP assembly and intracellular trafficking of the U-small nuclear RNA's, as well as mRNA splicing machines. Send curriculum vitae and names of two references (with phone numbers) to: **Personnel Office, Attn: Thoru Pederson, Ph.D., Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, MA 01545, USA.** *An Equal Opportunity/Affirmative Action Employer M/F/H.*

(NW4339)A

SPECIALIST IN AGRICULTURAL RESEARCH

How about working in Finland...?

Kemira is Finland´s largest chemicals company. It also has operations and production facilities in 14 other countries, mostly in Western Europe.

The company has a turnover of GBP 1.600 million, of which 75% comes from abroad.

Kemira has over 16 500 employees, over half of them working outside Finland.

The company´s main products are: fertilisers, TiO_2 pigments, paints, viscose fibres, various industrial chemicals, agricultural pesticides and explosives.

Kemira conducts a wide range of research activities, mainly at its Espoo Research Centre, near Helsinki, the capital of Finland. The Research Centre, which has a staff of 250, is responsible for research and development work on products and processes to meet the needs of Kemira´s domestic and foreign production plants.

We have a vacancy in our Agricultural Research Department for a

HEAD OF DEPARTMENT

to lead the Research Centre´s agricultural research work.

The department´s research is carried out in its laboratories and greenhouses, and on a research farm. Its staff currently numbers 25. Research is being done to develop fertilisers, agrochemicals and biotechnology products, particularly at the pot and field trials stage. The department is extensively involved in collaborative research with universities and research institutes, both at home and abroad.

The challenging task of the Head of Department will be the dynamic development of Kemira´s rapidly expanding, increasingly international agricultural research, in close collaboration with the other departments at the Research Centre.

You should offer:

- Solid evidence of scientific research work (Ph.D or equivalent)
- Sound experience of agricultural research or applied botany (forest science, relevant field of plant ecology, etc.) preferably also at international level
- The ability to collaborate internationally

We offer:

- A demanding and interesting leadership position in product development
- Salary commensurate with responsibilities
- Excellent opportunities for personal development and advancement in a large, dynamic company, rapidly becoming more international
- A modern, pleasant and flexible working environment.

For further information about the post, the Research Centre, Kemira, or even about Finland, contact Dr. Simo Kivisaari on 358-0-13211 (Central Administration), or Dr. Heikki Rosenqvist or Dr. Timo Törmälä on 358-0-80471 (Researc Centre). They can also arrange further contacts and forward written information.

Our address is: Kemira Oy Espoo Research Centre, Luoteisrinne 2, 02270 ESPOO, FINLAND.

All replies by October 20, 1989, please.

KEMIRA

(W6557)A

UNIVERSITY OF WARWICK
DEPARTMENT OF BIOLOGICAL SCIENCES

HIV RESEARCH

The award of a major grant from the AIDS Directorate of the MRC to the Virus Research Group within the Department has created six new positions to work on HIV. We are now seeking four Postdoctoral Fellows (IA)/Graduate Research Associates (IB) and a grade 3 Technician to complement the grade 5 Technician already in post. The grant is for three years, in the first instance, and the work will be carried out in a newly-constructed and equipped containment laboratory within the Department. General Research facilities with the Department are excellent. The research work will focus on three main areas:

1. Structure/function analysis of the *vif* gene Dr. M.A. McCrae)
2. Studies on the mechanism of virus induced cell fusion (Professor C.R. Pringle)
3. Analysis of the mechanism of virus neurtralisation (Professor N.J. Dimmock)

Candidates with virological and/or molecular biological experience are particularly encouraged to apply.

Potential applicants seeking general information about this new research venture should contact M.A. McCrae (0203–523524) (direct line) or, for specific information about any of the research areas, the appropriated project leader.

Appointments at the Postdoctoral level will be on the IA scale: £10,458–£16,665 p.a.; and Research Associate level will be on the IB scale: £9,816 to £12,381 p.a. The scale for the grade 3 Technician will be: £7,479 to £9,171 p.a.

Applicants should apply to **The Executive Officer (Noreen Rowe), Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL,** (0203–523517) (direct line) by sending a full c.v., including the names and addresses of two referees, quoting Ref. No. MRC/MAM/14. Closing date 26 October 1989. *An Equal Opportunties Employer*

(1732)A

DEPARTMENT OF PHARMACEUTICAL SCIENCES

CONTRACT RESEARCH OFFICER

A vacancy exists for a Contract Research Officer to work on a new anti-ulcer drug of biological origin, and may involve a limited amount of teaching. The post is funded by the British Technology Group for two years with a commencing salary in the range £9,816 to £11,088.

Applicants should hold a PhD in a biological subject such as biology or biochemistry or in a medical subject such physiology or pharmacology.

Further information can be obtained informally from Dr. D. A. Lewis (Tel: 021-359 3611, ext 4181/4168).

Application forms and further particulars may be obtained from the Personnel Officer (Academic Staff), Aston University, Aston Triangle, Birmingham B4 7ET (Tel: 021-359 0870 - 24hr answerphone), quoting Ref: 8929/6. Closing date for the receipt of applications is 20th October, 1989.

ASTON UNIVERSITY (1776)A

RGIT

ROBERT GORDON'S INSTITUTE OF TECHNOLOGY, ABERDEEN
SCHOOL OF FOOD AND CONSUMER STUDIES

LECTURER/SENIOR LECTURER BIOCHEMISTRY/PHYSIOLOGY

An experienced graduate, preferably with a doctorate, is required to lecture on our Honours Degrees in Nutrition and Dietetics. Relevant work experience and research interests are important as is the ability to successfully apply the subject to Human Nutrition.

The appointment may be made at the Senior Lecturer level and the post of Deputy Head is available to a suitably qualified candidate.

Salary scales: Lecturer £10935-£19623 per annum
Senior Lecturer-£18000–£23271 per annum

Assistance with removal expenses.

Informal enquiries to Dr Richard C Moody, Head of School. Tel (0224) 633611 ext. 521.

Further details from:
Personnel Department
RGIT
Schoolhill
ABERDEEN AB9 1FR
Tel (0224) 633611 ext. 249.

It is hoped to interview for the above appointment about the end of October 1989. (1763)A

THE INSTITUTE OF CANCER RESEARCH
(University of London)

SECTION OF CELL AND MOLECULAR BIOLOGY

A three-year Cancer Research Campaign funded post-doctoral position is now available to work with Dr. Alan Hall at the Chester Beatty Laboratories in Central London. The group is making use of a wide range of biochemical and molecular techniques to examine the function of ras and several ras-related guainio nucleotide binding proteins. The Chester Beatty Laboratory provides a strong stimulatory environment and excellent facilities for research. Candidates with a biological or biochemical background are encouraged to apply.
Salary: £12,108–£17,022 p.a. inclusive.

For further details ring A. Hall on 01-352 8133 ext. 5177.

To apply, please submit a Curriculum Vitae, in duplicate, with the names and addresses of two referees to **The Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL,** quoting ref. no. 10.89.S.N.47.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises. (1762)A

UNIVERSITY OF OXFORD

Research Laboratory for Archaeology

A POST-DOCTORAL CHEMIST is sought to manage and develop the chemistry of the Radiocarbon Accelerator Unit in the above laboratory. The Unit has a staff of 10 and unique facilities for research, development and routine radiocarbon dating of archaeological, environmental and art historical organic materials.

The appointment is initially for three years, with the possibility of renewal, on the 1A scale (£10,458-£16,665) depending on qualifications and experience. Experience in organic chemistry relating to terrestrial environments and/or biological tissues (e.g. bone) would be highly desirable. The appointee is expected mainly to initiate research into new methods; secondarily to develop methods for routine use, and to supervise routine operations.

Letters of application, to include details of qualifications and the names of two referees, should be sent to: **Dr R E M Hedges, Research Laboratory for Archaeology, 6 Keble Road, Oxford 0X1 3QJ,** preferably by 20th October. Enquiries about this post can be made to Dr Hedges on Oxford (0865) 273939. *An Equal Opportunities Employer.*

(1730)A

Abbott

As a worldwide industry leader with over $5 billion in sales, Abbott Laboratories has consistently proven itself capable of meeting the toughest challenges in the health care products marketplace. We've led the way with new treatments for cancer, epilepsy, and cardiovascular ailments. Our Erythrocin has become one of the most prescribed drugs. We've recently introduced Depakote, the fastest growing anticonvulsant on the market. And we're continuing to look ahead to major achievements, as seen by overall research commitments totaling $455 million in 1988.

The Neuroscience Research Division of Abbott's Pharmaceutical Products Division seeks top professionals to join our drug discovery team as we develop new agents to treat central nervous system disorders.

MOLECULAR NEUROPHARMACOLOGIST (Ph.D.) — The selected individual will be involved in the discovery of novel cognition enhancers and/or peptide satiety agents. Experience with in vitro test procedures inclucing receptor binding and second messenger systems is essential. A Ph.D. in Neuroscience, Pharmacology or Biochemistry, and at least 2 years relevant postdoctoral experience are required. **Reply to Job MP-7511.**

BEHAVIORAL PHARMACOLOGIST (Ph.D.) — The qualified candidate will have experience with and a demonstrated record of innovation in animal test procedures related to drug evaluation. At least 5 years of postdoctoral background is essential. Cognition and industry experience would be an advantage. **Reply to Job BP-7613.**

PHARMACOKINETICIST (Ph.D.) — The selected candidate will have a background in biochemistry or pharmacokinetics, and experience with in vivo and in vitro models of peptide drug absorption and metabolism. At least 2 years of relevant postdoctoral research experience is essential. Industry experience is desired. **Reply to Job PK-7612.**

MOLECULAR NEUROBIOLOGIST (Ph.D.) — The selected individual will participate in ongoing research involving trophic factors and gene-based drug therapies. A background in advanced molecular biology and a minimum of 2 years postdoctoral experience are essential. A demonstrated record of independent publication is also required. An interest in immune aspects of CNS function is preferred. **Reply to Job MN-7551.**

RESEARCH ASSOCIATES/BEHAVIOR (B.S./M.S.) — The qualified individual will have 2 or more years experience in Behavioral Pharmacology or a related area. Knowledge of animal surgery, drug administration and computer-based behavioral test procedures is preferred. **Reply to Job RAB-7613.**

RESEARCH ASSOCIATES/ELECTROPHYSIOLOGY (B.S./M.S.) — At least 2 years experience in extracellular, intracellular, and/or patch clamp recording from a variety of preparations is required. **Reply to Job RAE-7550.**

The Neuroscience Research Division is committed to a team approach to the discovery of new therapeutic entities and encourages its staff to maintain a high level of visibility within the neuroscience community.

Headquartered in an attractive suburban location just 30 miles north of Chicago, Abbott provides you with an excellent salary and benefits package including profit sharing and stock retirement plans. For consideration, please forward your resume, indicating Job Number interested in and salary history, to: **Patricia Handy, Corporate Placement, Abbott Laboratories, 1 Abbott Park Rd., Abbott Park, IL 60064.** Abbott is an Affirmative Action Employer.

MEETING BOUND?

Abbott representatives will be at the American Society for Neuroscience Conference in Phoenix, Oct. 30 - Nov. 2. To arrange an interview, please forward your resume to Patricia Handy, at Abbott Laboratories by October 23rd.

ABBOTT LABORATORIES

The University of Virginia
Beirne Carter Center for Immunology Research
Endowed Chair in Immunology

The University of Virginia is seeking an outstanding scientist to provide intellectual leadership for the Beirne Carter Center for Immunology Research. The Center is an interdepartmental program with the overall goal of fostering and coordinating research and research training in immunology. The Center is newly formed as the result of a gift from a University alumnus. Research will focus on the fundamental mechanisms underlying the induction and regulation of immune responses.

Funds are available to recruit scientists to fill several faculty positions. Candidates of those wishing to nominate outstanding individuals should direct their communications to:

Rodney L. Biltonen
Pharmacology Department
Box 448, Health Sciences Center
University of Virginia
School of Medicine
Charlottesville, VA 22908

The University of Virginia is an Equal Opportunity/Affirmative Action Employer

RADIOCHEMIST/NUCLEAR CHEMIST
National Institutes of Health
Public Health Service

National Cancer Institute
Division of Cancer Treatment
Clinical Oncology Program
Radiation Oncology Branch

Qualifications: Position involves research in labeled monoclonal antibodies with metallic radionuclides for clinical use in tumor diagnosis and therapy. A qualified applicant should have:

- A Ph.D. in Nuclear Chemistry or Radiochemistry
- Experience in working with high levels of radioactivity
- Ability to do careful scientific measurements
- Knowledge of radiochemical separations/and radionuclide purification

Biological or Radiopharmaceutical experience is desirable.

Salary: Dependent upon experience and qualifications.

Location of Position: Bldg. 10, National Institutes of Health, Bethesda, Maryland

For further information contact:

Dr. Otto A. Gansow
National Institutes of Health
Building 10, Room B3B69
9000 Rockville Pike
Bethesda, Maryland 20892
Telephone: (301) 496-5936

U.S. Citizenship Is Not Required

NIH IS AN EQUAL OPPORTUNITY EMPLOYER

(NW4320)A

At the Christian-Albrechts-University at Kiel (FRG)

a position as full professor (C4) in Biological Oceanography (in succession of Professor Gerlach) will be available for a botanist or zoologist from

1 April 1991.

Applicants should have experience in research and teaching in marine benthology. The position is combined with the directorship of the

Department of Marine Botany of the Institut fuer Meereskunde at the Christian-Albrechts-University Kiel.

It is expected that applicants are prepared to cooperate within the special research programme (Sonderforschungsbereich 313) "Sedimentation in the Greenland-Norwegian Sea".

The Institut fuer Meereskunde and the "Sonderforschungsbereich" are specially engaged in ecosystem research. Great importance is attributed to integrating aspects in research and teaching.

Especially women are requested to apply.

Applications with supporting documents are expected before

1 December 1989

by the

Dekan der Mathematisch-Naturwissenschaftlichen Fakultät
der Christian-Albrechts-Universität zu Kiel
Olshausenstraße 40
D–2300 Kiel 1, Federal Republic of Germany.

(W6558)A

TENURE-TRACK OPENING
DEPARTMENT OF BIOLOGY, U.C.L.A., PLANT CELL/DEVELOPMENTAL BIOLOGY

at the molecular level. The position is in the Division of Molecular, Cell, and Developmental Biology in the department, and involves participation in the interdepartmental Plant Molecular Biology Group. Potential research areas of interest include plant/microbe interactions, regulation of reproductive development, signal transduction mechanisms, and hormonal regulation of development, but other relevant areas will also be considered. Applicants should be committed to making a substantial contribution to teaching as well as to developing a strong and innovative research program.

Submit curriculum vitae, a statement of research and teaching interests, and have three letters of recommendation sent to: **Dr. E. M. Tobin, Chair, Search Committee, Biology Dept., U.C.L.A., Los Angeles, CA 90024** by December 1, 1989.

U.C.L.A. is an EO/AA Employer, and we encourage applications from women and members of minority groups. (NW4143)

POPULATION GENETICIST

The Department of Zoology, University of Florida, invites applications for a 9-month tenure-track position, beginning August 1990, at the assistant professor level. We are seeking a population geneticist with research emphasis in evolutionary, ecological, or conservation genetics. The successful candidate is expected to maintain a productive research program, teach an undergraduate course in general genetics, and develop a graduate course in his/her specialty. Applicants should submit a curriculum vitae; a succinct statement of research interests; a detailed outline of a proposed graduate course; representative publications; and names, addresses, and telephone numbers of four references by 4 December 1989 to: **Dr. Thomas C. Emmel, Chair, Population Geneticist Search Committee, Department of Zoology, University of Florida, Gainesville, Florida 32611.** *The University of Florida is an Equal Opportunity/Affirmative Action Employer.*

(NW4344)A

Graduate Biochemist

A key role in receptor pharmacology with A. Kaumann

Smith Kline & French Research Ltd. is a member of the SmithKline Beecham group of companies, one of the world's most innovative ethical pharmaceutical organisations with a strong commitment to research and development.

With a good degree in Biochemistry or a biological science and, ideally, four years' relevant experience, our receptor pharmacology group is a natural career move. Stimulating and varied work will keep you interested and stretched – carrying out and designing assays for biochemical and biophysical studies, using explorative research, routine experiments and screening, and taking responsibility for the maintenance of our biochemical tools and materials.

We are looking for a high degree of self-motivation, adept communication skills and the ability to work effectively within a highly talented team. A keen interest in, and knowledge of, computer data analysis would also be a considerable advantage.

In return, you can look forward to a competitive salary and benefits package, free BUPA and life assurance, flexible working hours, subsidised sports, social and canteen facilities and bonus schemes. Generous relocation assistance will be offered, if appropriate.

Please send your CV, quoting reference 100/89 to the Personnel Officer, Smith Kline & French Research Ltd, The Frythe, Welwyn, Herts AL6 9AR.

(1783)A

SK&F

ASSISTANT PROFESSOR DEVELOPMENTAL BIOLOGY DUKE UNIVERSITY

Applications are invited for a tenure track position beginning fall, 1990 in the Department of Zoology at Duke University. We are interested in candidates with high research promise in developmental biology, particularly in cellular or molecular aspects. Postdoctoral experience is desirable. Responsibilities include maintaining a vigorous research program and teaching an undergraduate course in developmental biology and a graduate course of choice.

Send curriculum vitae, description of research interests, and the names and addresses of three references by November 30, 1989 to: **Chair, Developmental Biology Search Committee, Department of Zoology, Duke University, Durham, NC 27706.**

Duke University is an Equal Opportunity/Affirmative Action Employer. Women and members of minority groups are strongly encouraged to apply. (NW4343)A

IMPERIAL COLLEGE (University of London)

POSTDOCTORAL or GRADUATE RESEARCH ASSISTANT HUMAN GENOME ANALYSIS

To join a group working on constructing a cosmid clone map of part of human chromosome II. The work involves use of a wide range of molecular biologoical techniques, including clone fingerprinting, DNA sequencing, cDNA cloning and analysis of large DNA fragments. Extensive use is made of computerised data analysis; where necessary, training will be provided. A successful postdoctoral candidate will be able to extend the work to include molecular genetic analyses of newly discovered genes on this chromosome.

Salary in the range RA1B scale £9,816–£12,381, plus £1,650 London Allowance or RA1A scale £10,458–£16,664, plus £1,650 London Allowance.

Further information from Dr Peter Little tel. (01) 589 5111 ext. 4164.

(1771)A

UNIVERSITY OF CAMBRIDGE

SENIOR AND JUNIOR PERMANENT UNIVERSITY POSTS IN GEOPHYSICS

As well as seeking candidates in those fields of the earth sciences to which physics has traditionally been applied, such as seismology, gravity and geomagnetism, we also seek people interested in applying physics to new areas, such as tectonics, igneous, metamorphic and sedimentary processes, geochemistry and planetary evolution.

Salary scale for senior post £14,170-£20,470, and for junior post £12,380-£15,370.

Applications, with c.v. (10 copies) and names of 3 referees, by 30 November, 1989 to **The Administrator, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ.** (1778)A

UNIVERSITY OF ABERDEEN

DEPARTMENTS OF ZOOLOGY AND GENETICS AND MICROBIOLOGY

MOLECULAR BIOLOGIST — DNA EVOLUTION

Applications are invited for the above post which is funded by the SERC (2 years) and is available immediately. The successful candidate will join a small team investigating mitochondrial DNA evolutionary relationships in lizards from the Canary Islands. Applicants with experience in the techniques of molecular biology, particularly PCR, DNA cloning and sequencing, will be especially welcome, although candidates with other relevant backgrounds are encouraged to apply. Starting salary from £10,458.

Application forms from the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX (tel 0224 273500)**, to whom applications (2 copies) should be returned by 27 October 1989 quoting reference number LW/044. (1769)A

UNIVERSITY OF NEWCASTLE UPON TYNE

NEWCASTLE RESEARCH GROUP IN FOSSIL FUELS AND ENVIRONMENTAL GEOCHEMISTRY

THREE LECTURERSHIPS are now available and the University would be interested in applications from individuals who wish to work in a multidisciplinary research environment and who have a background in one or more of the following areas:

Petroleum geochemistry
Petroleum reservoir engineering
Structural controls in migration and reservoiring of oil and gas
Sedimentary diagenesis and geochemistry
Numerical modelling of geological processes
Environmental microbiology
Hydrogeology

The research group, formed from an expansion of the Organic Geochemistry Unit in the Department of Geology in the recently completed reorganisation of Earth Science Departments in British universities, is currently pursuing active research in the following areas: Geochemistry and petrography of fossil fuels; Petroleum generation in sedimentary basins; Physics and chemistry of hydrocarbon migration; Rock fluid relationships in petroleum reservoirs; Pollutants in the environment; Microbiology and geochemistry of recent and ancient sediments; Palaeoclimate/palaeoenvironmental reconstructions; Molecular palaeontology.

With the status of a Postgraduate Research Institute and awarded a top grading of "5" in the current UFC research selectivity exercise, the group will become a major centre for pure and applied research in the areas of fossil fuel and environmental geochemistry.

Salary will be at an appropriate point on either the Lecturer Grade A scale: £10,458 – £15,372 p.a. or Grade B scale: £16,014 – £20,469 p.a. according to qualifications and experience.

Further particulars may be obtained from the Senior Assistant Registrar, Establishments Section, The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU with whom applications (3 copies), together with the names and addresses of three referees, should be lodged not later than 27th October 1989. (1773)A

POSTDOCTORAL POSITION

One year postdoctoral position (with annual renewal depending on performance) to study RNA metabolism. Qualified candidate must possess Ph.D. in biochemistry or molecular biology with experience in DNA cloning and RNA. Salary $20,000 per annum. Please forward résumé to **Civilian Personnel, Henry M. Jackson Foundation, 4301 Jones Bridge Road, Bethesda, MD 20814–4799.** (NW4346)A

RESEARCH ASSOCIATE

Position available immediately to study Ca^{2+} release protein in skeletal sarcoplasmic reticulum. Requires Ph.D. degree in Physiology/Biochemistry with two/three years of postdoctoral experience in protein chemistry, immunology techniques, Ca^{2+} transport studies. Familiarity with protein reconstitution is desirable. Salary is $23,000 and negotiable, depending on qualifications. Reply with curriculum vitae and three letters of recommendation to **Dr. Guy Salama, 670A Scaife Hall, Dept. of Physiology, Univ. of Pittsburgh, Pittsburgh, PA 15261.** *The University of Pittsburgh is an Equal Opportunity/Affirmative Action Employer.* (NW4326)A

POSTDOCTORAL POSITION

available immediately for molecular biologic studies of a human metastases-associated gene. Experience with cDNA cloning, DNA sequencing and expression vectors is highly desirable. Send application including curriculum vitae, a brief summary of previous training, experience and research goals along with the names of three references to: **George D. Sorenson, MD, Dept. of Pathology, Dartmouth Medical School, Hanover, NH 03756.** (NW4336)A

NATIONAL INSTITUTE FOR BIOLOGICAL STANDARDS AND CONTROL

DIVISION OF IMMUNOBIOLOGY

TENURE TRACK SCIENTIST

As a result of expansion, the Division of Immunobiology has a vacancy for a post-doctoral scientist.

The work is in the field of cytokines, with particular reference to studies of the biological and molecular characterization of interleukins and colony stimulating factors.

Applicants should have at least two years post-doctoral experience. This position is tenable for five years and post holders will be reviewed for tenure not later than the fourth year.

Salary will be on a scale up to £17,022 per annum depending on experience and qualifications.

Informal enquiries may be made to Dr R Thorpe, extension 269.

For further details and to apply please contact the Personnel Office, NIBSC, Blanche Lane, South Mimms, Herts. EN6 3QG. Tel: 0707 54753 Ext. 458.

Please quote reference number IM/130A.

Closing date for applications is 27th October 1989. (1757)A

Post Doctoral Research Fellowship

Smith Kline & French Ltd, a member of the SmithKline Beecham group of companies, is one of the world's most innovative ethical pharmaceutical organisations with a strong commitment to research and development.

A PhD and a clear understanding of receptor binding techniques will prove essential in this stimulating post-doctoral position. A knowledge of the purification and isolation of proteins and cell cultures is sought and computer literacy would be an advantage.

Working in Dr. A.J. Kaumann's receptor pharmacology group you'll be encouraged to participate in scientific meetings and to publish research findings.

The rewards for this two (or possibly three) year contract include a salary of between £13,500 and £15,000 and a range of benefits that includes free BUPA and life assurance, flexible working hours, subsidised sports, social and canteen facilities, and bonus schemes. Generous relocation will be offered, if appropriate.

Please send your CV, quoting reference 74/89 to the Personnel Officer,
Smith Kline & French Research Ltd.,
The Frythe, Welwyn, Herts AL6 9AR.

ASSISTANT OR ASSOCIATE PROFESSOR EVOLUTIONARY/POPULATION GENETICS

Tenure track position open September 1990 for an evolutionary or population geneticists. Post-doctoral experience desirable. Expected to develop a productive research program and interact with strong marine ecology and molecular genetics groups in the department. Application of molecular methodology to field populations is of particular interest. Generous start-up funding and other allowances negotiable. Graduate and undergraduate teaching responsibilities.

Send resumé and publications. Three or more reference letters from professional associates requested.

Application deadline 1 December 1989.

Dr. Sarah Woodin, Chair, Population Genetics Search Committee, Department of Biological Sciences, University of South Carolina, Columbia, SC 29208, (803) 777-5084.

An Equal Opportunity/Affirmative Action Employer. (NW4294)A

UNIVERSITY OF CAMBRIDGE: DEPARTMENT OF PAEDIATRICS

UNIVERSITY LECTURESHIP (NON-CLINICAL)

Applications are invited for the above post in the Department of Paediatrics based at Addenbrooke's Hospital. Applicants must have experience in molecular biology and will be required to direct the laboratory-based research programme of the Department in close collaboration with the Head, Professor Ieuan A. Hughes. The specific research interest of the Department is the molecular biology of steroid hormone production and action as it relates to disorders of sexual differentiation. Salary scale £14,169 to £21,852 according to age.

Further information may be obtained from **Miss S.M. Pinnock, Secretary of the Clinical School, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ,** to whom applications (fifteen copies), together with the *curriculum vitae* and the names of three referees, should be sent so as to reach her not later than 8 November 1989.

The University follows an equal opportunities policy. (1738)A

UPJOHN POSTDOCTORAL PROGRAM

The Upjohn Company has initiated a broad multi-disciplinary postdoctoral program in the biomedical, pharmaceutical, and computer sciences.

Nearly every discipline and specialty is available within Upjohn, and the opportunities for exciting innovative research are excellent.

Scientists with Ph.D., M.D., or D.V.M. degree with interests in pharmacology, cellular and molecular biology pharmacokinetics, drug metabolism, as well as computational, medicinal, analytical and pharmaceutical chemistry are encouraged to apply.

Areas of particular interest are atherosclerosis, Alzheimer's disease and mental performance, inflammation biology, diabetes, thrombosis and thrombolysis, oxygen radicals and ischemic injury, cardiovascular diseases, cancer, cellular growth and differentiation, molecular biology of plants, immunology, virology, parasitology and growth regulation of animals.

Upjohn's commitment to its employees is demonstrated by its competitive compensation and benefits package in addition to a stimulating multi-disciplinary research environment at our modern research laboratories in Kalamazoo, Michigan. Interested applicants are invited to forward their resume and a statement of their research interests and experience in strict confidence to: The Upjohn Company, Position #5637-BA, Corporate Employment, Kalamazoo, MI 49001. We are an Equal Opportunity Employer M/F.

NATIONAL INSTITUTES OF HEALTH RESEARCH ASSOCIATE/ POSTDOCTORAL FELLOW: PHYSIOLOGY

The Clinical Investigations and Patient Care Branch of the National Institute of Dental Research is seeking two individuals to participate in ongoing studies of ion transport and signal transduction events related to fluid secretion in salivary glands following neurotransmitter stimulation. For the Research Associate position the candidate should have 3-5 years of previous postdoctoral training. This position requires strong experience in the study of ion fluxes in vesicle preparations and/or intact cells. Knowledge of fluorescence methods for determining intracellular ion concentrations and familiarity with secretory systems are also highly desirable. For the Postdoctoral Fellowship, the candidate cannot have more than 2 years of previous postdoctoral training and should have some experience in studying signal transduction steps (e.g., receptor binding, G protein activation, second messenger generation). The salary for each position is competitive and depends on background and experience. The positions are available in April, 1990.

Send curriculum vitae, bibliography and the names of three references to either Dr. R. James Turner, Membrane Biology Section (for Research Associate), or to Dr. Bruce J. Baum, Secretory Physiology Section (for Postdoctoral Fellow), at the **National Institute of Dental Research, National Institutes of Health, Building 10, Room 1A06, 9000 Rockville Pike, Bethesda, MD 20892, U.S.A.** (NW4350)A

Institute of Terrestrial Ecology

Monks Wood, Huntingdon

Applications are invited for two Post-Doctoral Research Fellows based at the Institute of Terrestrial Ecology, Monks Wood:

Mathematical Models of Vegetation

The successful candidate will be required to develop predictive models of vegetation change in relation to soil, site and tree species in new farm woodland. The appointment has been awarded jointly to ITE and to the Soil Survey and Land Research Centre (Cranfield Institute of Technology) under the NERC Special Topic Programme in Farm Forestry. Applicants should have a PhD or equivalent, preferably in plant ecology or soil science, with some computing experience. Ref. 1.

Ecology/Ornithology

The successful candidate will be required to investigate the bird population of small woods. The aims are to find to what extent the principles of island biogeography can be applied to the breeding bird populations of small woods, and the importance of dispersal in maintaining these populations. The work will involve enumeration of species numbers in a wide range of woods, and extensive trapping and ringing. Applicants will be expected to have obtained or due to obtain a PhD in an appropriate discipline and will be required to have a sufficient background in ornithology. Experience of bird ringing and computer programming would be desirable. A driving licence is essential. Ref. 2.

The appointments are for a period of three years.

Salary will be in the range of **£10,678 to £14,909** per annum dependent upon qualifications and experience and benefits include generous leave allowance and non-contributory pension scheme.

The Institute of Terrestrial Ecology is a component body of the Natural Environment Research Council.

Further information and application forms, quoting the appropriate reference number, may be obtained from Admin Headquarters, Institute of Terrestrial Ecology, Monks Wood, Abbots Ripton, Huntingdon, PE17 2LS, telephone 04873-381.

Closing date for completed application forms is October 26th 1989.

Natural Environment Research Council is an Equal Opportunities Employer.

QUADRANT RESEARCH FOUNDATION

Cambridge Research Laboratories

ost available for Research Assis-nt (Postdoc or graduate) in mol-ar biology labs for project on oning of yeast sugar synthase ne. Experience in molecular ology required. Send c.v. and 2 tters of reference to Dr B. oser, QRF. 181A Huntingdon oad, Cambridge, CB3 0DJ by ctober 20th. (1770)A

Post Doctoral Positions in Biochemistry and Molecular Biology

Two positions are available immediately to study the mechanism of action of specific deoxynucleotide metabolizing enzymes as well as the regulation of their genetic expression in eukaryotes and prokaryotes. Gene isolation and amplification of their protein products will be required. Once obtained substrate and regulatory sites on the protein products will be determined by functional group specific reagents and affinity labels. In addition site specific mutagenesis will be employed to establish the relation of structure to function in these enzymes. Cloning and sequencing experience desirable. The research will be conducted in a well-equipped core facility. Compensation from Health Research Inc. dependent upon experience. Send resume and three references to: **Dr. Frank Maley, Wadsworth Center for Laboratories and Research, Empire State Plaza, Box 509, Albany, NY 12201.** *An equal opportunity Affirmative Action Employer.* (NW4303)A

Postdoctoral Research Associate

A position is available to study molecular and cellular aspects of several **mRNA binding proteins.** Topics include a recently identified protein kinase that phosphorylates eIF-4E, the use of monoclonal anti-eIF-4E antibodies to probe protein-mRNA and protein-protein interactions and the physiologic effect and regulation of eIF-4E modifications in Hep G2 cells. Experience in molecular and cell biology or protein chemistry required. Please submit a letter of application, curriculum vitae and names of three references to: **Curt H. Hagedorn, C-2104 MCN, Vanderbilt University School of Medicine, Nashville, TN 37232.** (NW4349)A

BEHAVIOURAL PHARMACOLOGIST

Welcome to a world of outstanding opportunities

RHONE-POULENC SANTE, one of the top three European pharmaceutical groups, is seeking a Behavioural Pharmacologist to set up and manage a laboratory devoted to the study of learning and memory processes through behavioural and pharmacological tests.

Good post-doctoral experience is needed, particularly in applied pharmacology in the pharmaceutical area.

Knowledge of French is not initially required.

The position is based near by Paris.

Please send your CV, quoting reference 61672 to Media-System, 6 impasse des Deux Cousins, 75849 Paris Cedex 17, France.

Cancer Research Campaign Mammalian Cell DNA Repair Research Group

Research Assistant in Biochemistry/Molecular Biology

We are looking for a graduate research assistant to join a research team to work on biochemical and molecular aspects of DNA repair. This post is available immediately and, for a suitable person, will extend for five years from January 1st 1990.

We are looking for an individual who can take responsibility for running and developing assays for DNA repair. Applicants should have a good first degree. Experience in protein and/or nucleic acid biochemistry, or a background in microbiology or molecular biology would be useful.

Starting salary will depend on age and experience and will be in the University of Cambridge Research Assistant Graduate Scale (£9,196 at age 22 to £12,381).

Applications in writing, together with c.v. and names and addresses of two scientific referees should be sent to **Mr J.R. Andrews, Department Secretary, Department of Zoology, Downing Street, Cambridge CB2 3EJ.**

Further information can be obtained informally by contacting Dr. R.T. Johnson (0223) 336672. (1785)A

POSTDOCTORAL POSITION available for Ph.D. in lipoprotein metabolism and atherosclerosis in nonhuman primates under the supervision of Dr. Rampratap S. Kushwaha, Associate Scientist. Applicant should be experienced with methods in protein biochemistry and metabolism. Annual salary ranges upward from $21,070, with consideration for prior relevant postdoctoral experience. Position is available for two years with opportunities for further extension or conversion to a staff position. Please send curriculum vitae, a description of research interests, and names and telephone numbers of three references, including major professor, to **Personnel Director (6), Southwest Foundation for Biomedical Research, P.O. Box 28147, San Antonio, TX 78284.** *Equal Opportunity Employer m/f.* (NW4355)A

THE UNIVERSITY OF BRITISH COLUMBIA
Department of Psychiatry

The Division of Neurological Sciences (Kinsmen Laboratory) in the Department of Psychiatry at the University of British Columbia invites applications from outstanding individuals with a commitment to excellence in research in Neuroscience for a tenure track position at the rank of Assistant Professor. Applicants should have a Ph.D. or M.D. degree, postdoctoral training, and have shown clear evidence of a capacity for independent, original research. The Division is particularly interested in recruiting an individual with an interest in neurobiology as it applies to human psychiatric diseases such as schizophrenia or major affective illness. The Division offers excellent research facilities. The successful applicant will be expected to be a strong candidate for Medical Research Council of Canada Scholarship support. Salary will be commensurate with qualifications and experience and subject to final budgetary approval.

Applicants should send *curriculum vitae,* list of publications, a brief summary of research plan, and the names and addresses of three referees to: **Dr. H.C. Fibiger, Professor and Head, Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, 2255 Wesbrook Mall, Vancouver, B.C., Canada, V6T 2AJ.** In accordance with Canadian immigration requirements, this advertisment is directed Canadian citizens and permanent residents. Applications will be accepted until December 15, 1989. Position starting date will be July 1, 1990. (NW4357)A

MRC LABORATORIES
THE GAMBIA

Immunologist

(Malaria Laboratory)

Joining the malaria research group, you will be expected to develop a research programme in the area of cell mediated immunity in malaria. Thus, considerable experience in cellular immunology is needed, preferably at post-doctoral level; experience of malaria is desirable but not essential.

The malaria laboratory is well equipped. Strong links have been established with other malaria laboratories in Europe and the USA and you will be expected to develop these collaborations.

Salary, which will be on the MRC international scale, will be determined by qualifications and experience. The duration of contract that will be offered is open to negotiation but a minimum period of 2 years in The Gambia is required.

Applications should be submitted to Dr David King, MRC Head Office, 20 Park Crescent, London W1N 4AL from whom further details may be obtained. The closing date for applications is 1st Nov 1989.

DEPARTMENT OF BIOCHEMISTRY
UNIVERSITY OF OXFORD

MEDICAL RESEARCH COUNCIL
BIOCHEMICAL AND CLINICAL MAGNETIC RESONANCE UNIT

Postdoctoral Biochemist (Ref: BR/311)

Applications are invited for a NON-CLINICAL SCIENTIFIC post tenable for 3 years in the first instance. We are seeking someone with interest in cellular biochemistry and mammalian cell culture to join a multi-disciplinary Unit, investigating the control of metabolism and its implications in human disease.

Salary will be at an appropriate point on the scales for University non-clinical academic staff.

Applications, including a full curriculum vitae and the names and addresses of two referees, should be sent to:

Professor G.K. Radda, FRS:

Tel: (0865)-275274; Fax No. (0865)-515059

from whom further particulars can be obtained.

An Equal Opportunity Employer. (1759)A

DEPT OF BIOCHEMISTRY, SOUTH PARKS ROAD,OXFORD,OX1 3QU

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)

GRADUATE RESEARCH ASSISTANT/TECHNICIAN

Applications are invited for the above research position in the Department of Biochemistry to work with Drs M C Sugden and M J Holness. The post is tenable for two years in the first instance. Applicants should hold a degree or equivalent (e.g. HND).

The research, funded by the British Heart Foundation, will investigate the factors regulating cardiac fuel selection and utilization. The successful candidate may be eligible to register for a higher degree.

Starting salary: up to £10,846 p.a. (inclusive of London Weighting) depending on age and experience.

Applications in duplicate, including a c.v. and the names of two professional referees, should be sent to **Dr M D Sugden, Department of Biochemistry, The London Hospital Medical College, Turner Street, London E1 2AD (telephone 01-377 7000 ext. 3133)** from whom further details can be obtained. (1735)A

INSTITUTE OF PLANT SCIENCE RESEARCH
CAMBRIDGE LABORATORY

Head of Brassica Research Department

The Laboratory is seeking to appoint a Head for the newly created Brassica Research Department to lead and be responsible for a multi-disciplinary group of scientists consisting of nine project leaders plus support staff. The main aim of the Department is to study the genetics, biochemistry and physiology of Brassicas with the view to providing the means for their directed manipulation for Brassica crop improvement, with particular emphasis on oilseed rape. The Head of Department will be expected to liaise with Industry in the setting up of sponsored and collaborative research. In developing a dynamic and innovative programme, an important aspect will be the exploitation of research developments occurring in other Departments of the IPSR.

Initially the successful applicant will be based at the Cambridge Laboratory but in March 1990 will transfer to new laboratories at the John Innes Institute site at Norwich.

Candidates will have appropriate academic qualifications together with a distinguished record of personal research and a succesful record in research management.

Salary will be on the Unified Grade 6 scale £21,633 p.a.-£28,170 p.a.

Applications (quoting ref. PB344) with full CV and the names of three referees should be sent to **Mrs L. Cliff, Institute of Plant Science Research (Cambridge Laboratory), Maris Lane, Trumpington, Cambridge CB2 2JB** by Friday 27th October 1989.

The Institute is an Equal Opportunities Employer. (1787)A

UNIVERSITY OF READING
DEPARTMENT OF MICROBIOLOGY

RESEARCH OFFICERSHIP

Applications are invited for a **RESEARCH OFFICERSHIP** tenable for 3 years, to commence as soon as possible. The Officer will join a dynamic and expanding research group led by Dr. M.J.C. Crabbe. The project, funded by AFRC, is to study the cellular uptake and degradation of Maillard food products, and compare them with the mechanisms for uptake and degradation of Maillard products resulting from hyperglycaemia (diabetes). Techniques in cell and protein biochemistry will be used. Candidates should have a good honours degree in the biochemical- or chemical-related sciences. Starting salary up to £10,458 p.a. There is the possibility of registration for a Ph.D. Curriculum vitae, including the names and addresses of two referees, may be sent directly to Dr. M.J.C. Crabbe, Reader in Microbiology, London Road, Reading RG1 5AQ (Tel: (0734) 318894; FAX: (0734) 750140; Email: SKSCRABB @ UK. AC.RDG.AM.CMS), from whom further details may be obtained. Please also APPLY FOR APPLICATION FORM (apart from overseas applicants) to **Personnel Officer, University of Reading, P.O. Box 217, Whiteknights, Reading RG6 2AH, telephone (0734) 318754.** *Please quote R8966.* (1734)A

UNIVERSITY OF EDINBURGH
FACULTY OF VETERINARY MEDICINE

LECTURER/SENIOR LECTURER IN VETERINARY REPRODUCTION

Applications are invited from veterinary graduates with experience in reproduction for a post based at the Veterinary Field Station, Royal (Dick) School of Veterinary Studies, Easter Bush, Roslin. The appointee will be expected to head the reproduction research programme and play a role in post-graduate and undergraduate training and clinical work. It is likely that the successful candidate will have a Ph.D. or have demonstrated research expertise and will have an active programme of investigation.

The post is available from 1st October 1989. Salary will be on the lecturer/senior lecturer scale £16,014-£24,285 per annum, with placing according to qualifications and experience.

Particulars of appointment may be obtained from the **Personnel Officer, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS,** with whom applications (four copies including a *curriculum vitae* and the names and addresses of three referees) should be lodged no later than 20th October 1989.

Please quote reference 1466. (1741)A

SIR WILLIAM DUNN SCHOOL OF PATHOLOGY
UNIVERSITY OF OXFORD

GENOMIC DNA SEQUENCING PROJECT
Research positions

Applications are invited for a postdoctoral fellow and a graduate research assistant to join a large-scale international collaborative project to determine the complete DNA sequence of the *Bacillus subtilis* chromosome. The project represents a pilot scheme for subsequent projects with the ultimate goal of determining the human genome sequence. The work will involve the use of existing state-of-the-art cloning and sequencing technologies and, potentially, participation in the development and testing of the next generation of sequencing methods. Opportunities will also present themselves for persons interested in the development of new computer software for use in, for example, the handling and manipulation of DNA sequence data on the megabase scale, discrimination of coding and non-coding regions, and for studying the gross structure of the bacterial chromosome. Informal enquiries may be made to Dr. J. Errington (0865-275558). Salary will be at the appropriate level on the academic related 1A (postdoctoral) £10458-£16665 or 1B (graduate) £9816-£14169 scale. Funding, from the EEC Science programme, is initially available for 18 months but it is likely to be extended for up to five years subsequently.

Applications in writing, together with c.v. and names and addresses of two referees, should be sent to **The Administrator, Sir William Dunn School of Pathology**. Closing date for applications 27 October 1989. *The University is an equal opportunity employer.* (1784)A

THE ADMINISTRATOR, SOUTH PARKS ROAD,OXFORD, OX1 3RE

FACULTY POSITIONS

Assistant/Associate Professor

Department of Biochemistry

University of Illinois College of Medicine at Chicago

Applications and nominations are invited for tenure-track faculty positions to be filled in the 1990 academic year. We are seeking candidates who are using modern molecular biological approaches to investigate problems in the general area of biogulation including signal transduction/membrane interaction, growth control and cell differentiation. Exceptional applicants in other areas will also be considered. Applicants should have a Ph.D., postdoctoral experience, a strong record of research accomplishments, and demonstrate potential for the development of an independent research program. At the tenured level, applicants must have a strong record of research accomplishment. The Department of Biochemistry consists of 20 full time faculty and has hired several new faculty in the areas of gene expression and membrane biology in recent years. The Department and College have research support facilities that include nucleic acid and protein synthesis and sequencing. Applications should include a curriculum vitae, a summary of current and future research plans and the names of at least three individuals for references. Application deadline is December 31, 1989. Send applications or nominations to: **Robert V. Storti, Department of Biochemistry (M/C 536), University of Illinois College of Medicine at Chicago, 1853 W. Polk St., Chicago, IL. 60612.**

The University of Illinois is an Affirmative Action/Equal Opportunity Employer. (NW4345)A

UNIVERSITY OF OXFORD

DAVID PHILLIPS PROFESSORSHIP OF MOLECULAR BIOPHYSICS

The electors intend to proceed to an election to the David Phillips Professorship of Molecular Biophysics with effect from as early a date as can be arranged. The stipend of the professorship is at present £28,521.

Applications (ten copies, or one from overseas candidates), naming three referees should be received not later than 27 November 1989 by the Registrar, University Offices, Wellington Square, Oxford 0X1 2JD from whom further particulars may be obtained. (1751)A

The University is an Equal Opportunity Employer

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
DEPARTMENT OF PHYSIOLOGY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Research Assistantship funded by the MRC for 2½ years for studies of the physiology and pharmacology of inhibitory postsynaptic potentials in thalamus. The laboratory has a long term interest in the physiology and pharmacology of excitatory and inhibitory amino acid mediated synaptic transmission. Techniques include: intracellular recording, current and voltage clamp, iontophoresis, spike triggered averaging, intracellular dye injection and reconstruction of neurones. Experience of some of these techniques would be helpful but enthusiasm for neuroscience, willingness to learn and aptitude are more important. A fully operational rig is available for this project in a well funded laboratory in which the required techniques are in routine use.

Salary is on the 1A scale.

Informal enquiries to **Dr. Alex Thomson, Department of Physiology, address as below, 01–431–5269.**

Applications (***TWO copies of C.V.*** plus names and addresses of two referees) should be sent to the **School Office, R.F.H.S.M., Rowland Hill Street, London NW3 2PF.** Please quote ref. *P/PRA/59.* (1749)A

COOPERATIVE EXTENSION SPECIALIST POSITION

Plant Biotechnology

The University of California at Berkeley

The Department of Plant Biology invites applications for a Cooperative Extension Specialist position in the area of plant biotechnology. The appointee will be expected to develop a research program which deals with applied aspects of plant biotechnology and will be expected to serve as the liaison between the department and organizations, such as industry, governmental and public interest groups, who have an involvement with the area of plant biotechnology. Other responsibilities include the development of educational programs, identifying issues and research needs in biotechnology and the preparation of reports for government and public interest groups with an ongoing interest in plant biotechnology.

Applicants should have a Ph.D. degree in an appropriate field, such as molecular biology, plant molecular biology, plant pathology or plant physiology and an understanding of the practical aspects of plant technology. A demonstrated ability to carry out an appropriate applied research project that is relevant to the research goals of the department is required. Applicants should send a curriculum vitae, a two page statement describing their proposed research program as well as a description of their broader role in the plant biotechnology field and names and addresses of three references to: **Dr. Richard Malkin, Chair, Department of Plant Biology, 345 Mulford Hall, University of California, Berkeley, CA 94720.** Closing date for applications is December 31, 1989, and it is anticipated the position will be filled by June 30, 1990. *The University of California is an Equal Opportunity, Affirmative Action Employer.* (NW4363)A

NEW CANCER RESEARCH GROUP
SASKATOON CANCER CENTRE
AND THE UNIVERSITY OF SASKATCHEWAN

The Saskatoon Cancer Centre is seeking three individuals with experience in such areas as tumor biology, oncogenes, growth factors, molecular biology or related areas to join an existing group of researchers in a new cancer research group. The group will be housed in the Saskatoon Cancer Centre which contains over 1000 m^2 of new laboratory space. Initial operating funds as well as funds for major equipment and support services are available. Appointments are of a permanent nature with the initial funding from a Terry Fox Regional Development Grant from the National Cancer Institute of Canada. Successful candidates will also receive appointments at the University of Saskatchewan commensurate with their level of experience. Candidates with a Ph.D. or M.D. degree and at least two years of postdoctoral training are encouraged to apply by submitting a curriculum vitae and names of three references to: **Dr. D. White, Director, Saskatoon Cancer Centre, Saskatoon, Saskatchewan, Canada S7N 0X0.** *In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents.* (NW4358)A

Colorado State University

seeks two **MOLECULAR BIOLOGISTS** for tenure track **ASSISTANT PROFESSOR** positions in the Department of Biochemistry. The department occupies a new building containing modern laboratories and a full complement of core facilities for biochemistry, molecular biology and cell biology. Candidates must have a Ph.D. degree, postdoctoral experience, and a demonstrated ability to develop an independent and productive research program. The successful applicant must effectively participate in undergraduate and graduate teaching of biochemistry or molecular biology. Individuals with research interests in all areas of molecular biology including *plant gene expression* or *molecular neurobiology* are encouraged to apply. Deadline for applications is November 1, 1989. Send curriculum vitae, a statement of research interests and the names of three references to: **Dr. N.F. Curthoys, Department of Biochemistry, Colorado State University, Fort Collins, CO 80523.** *CSU is EEO/AA Employer.* E.O. office, 314 Stu. Serv. Bldg. (NW4361)A

Cancer Research Campaign

BEATSON INSTITUTE FOR CANCER RESEARCH AND DEPARTMENT OF VETERINARY PATHOLOGY, GLASGOW UNIVERSITY

POSTDOCTORAL RESEARCH WORKER AND SCIENTIFIC OFFICER

Applications are invited for staff to join an interdepartmental group working with Dr. M.S. Campo and Professor W.F.H. Jarrett on the project "Prophylactic and Therapeutic Vaccination against Papillomavirus Infection". This involves the analysis of the humoral and cellular immune response to papillomavirus infection and the investigation of vaccine production against both bovine and human papillomavirus. The work is financed for five years by the Cancer Research Campaign from January 1990.

Experience in DNA manipulation and cloning, cell culture and protein handling will be an advantage in both posts but training is available for successful applicants with a different background. The successful applicants will have a Ph.D. and a B.Sc/HNC in biological sciences respectively. Salary for the postdoctoral worker will be on the Research Ia scale, £10,458 to £16,665 and the Scientific Officer scale is £9,088 to £11,654 with placing according to qualifications and experience. Applications with a c.v. and the names and addresses of two referees by October 31st to **Dr. M.S. Campo, The Beatson Institute for Cancer Research, Garscube Estate, Bearsden, Glasgow G61 1BD, from whom further details may be obtained by 'phoning 041–942 9361.** (1742)A

INSTITUTE OF PLANT SCIENCE RESEARCH CAMBRIDGE LABORATORY

The Institute is seeking to appoint a Scientific Officer/Higher Scientific Officer to support the research programme investigating the genetical control of agronomic characters in wheat and barley. Experience in plant genetics, cytogenetics, tissue culture or biochemical techniques is required with an interest in carrying out experiments both in the laboratory and field.

The appointee will be based initially at the Cambridge Laboratory but will be required to move to the John Innes Institute, Norwich on completion of new laboratories in early 1990. The appointee will qualify for transfer terms.

Qualifications: Higher Level — A degree HND, HNC or equivalent in an Agricultural or Biological subject with at least 5 years relevant post-qualifying experience.

Lower Level — Honours degree or equivalent in an Agricultural or Biological subject.

Salary will be £9,131-£12,223 at Scientific Officer grade or £10,678-£14,909 at Higher Scientific Officer grade.

Applications with full CV and the names of two referees to **Mrs L Cliff, Institute of Plant Science Research, Cambridge Laboratory, Maris Lane, Trumpington, Cambridge CB2 2JB** quoting reference CR/356 by 27th October 1989.

The Institute is an Equal Opportunities Employer (1765)A

RESEARCH INSTRUCTOR

Laboratory of Molecular Immunology at leading cancer institute invites applications for the post of research instructor to study the intracellular transport of the T-cell receptor for antigen. Duties include use of modern recombinant DNA technology (site-directed mutagenisis, fusion protein production and DNA transer into eukaryotic cell lines.)

Candidates must have a Ph.D. in Biochemistry or Cell Biology and a minimum of three years postdoctoral research experience using subcellular membrane fractionation, immunoadsorption and immunofluorescence techniques in the study of membrane kinetics and compartmentalization. A thorough understanding of the methods used to study the biochemistry and physiology of membrane traffic and membrane receptor movement is required. A demonstrated record of productivity in studying the cell biology of intracellular traffic and molecular biology of T-lymphocyte antigen receptors through publication in recognized professional journals is also required. Salary: $30,000 per annum.

Interested individuals should send their Curriculum Vitae and a list of publications to: **Department of Employment and Training, Special Programs, Hurley Bldg., 19 Staniford Street, Boston,** MA 02114 and refer to Job Order #91288. (NW4342)A

FACULTY POSITION IN MOLECULAR IMMUNOLOGY

DEPARTMENT OF BIOCHEMISTRY AND BIOPHYSICS IOWA STATE UNIVERSITY

The department invites applications for a tenure-track position at the level of assistant or associate professor. The successful applicant will be expected to develop an independent research program in some molecular aspect of the immune system; possible areas of interest include, but are not limited to, protein chemistry, molecular structure, and molecular genetics. The appointee will be expected to have an interest in interacting with existing research programs in the department, to assume moderate teaching duties, and to participate in the interdepartmental Immunobiology Program. Generous start-up funds and laboratory space in the new Molecular Biology Building are available. Applicants should send curriculum vitae, statement of research plans, and the names and addresses of three references by December 15th, 1990 to: **Dr. Alan M. Myers, Department of Biochemistry and Biophysics, 397 Gilman Hall, Iowa State University, Ames, IA 50011.**

Iowa State University is an Affirmative Action/Equal Opportunity Employer. Applications from women and minority candidates are especially encouraged. (NW4348)A

MOLECULAR GENETICIST

The Department of Pathology at The Children's Hospital, is searching for a qualified individual to supervise a service laboratory in molecular genetic diagnostic testing. For the appropriate candidate, an academic appointment would be available in the University of Colorado School of Medicine, along with opportunities to pursue research efforts. Applicants must have a Ph.D. in molecular biology or a related field, have experience in molecular genetic testing, and be eligible for board certification in Molecular Genetics by the American Board of Human Genetics on or before June 1990.

Send curriculum vitae, a statement of career objectives and current and/or planned research, and the names, addresses, and phone numbers of three individuals who have agreed to act as references to: **Dr. Vincent Wilson, Director of Molecular Genetics, Pathology Department, The Children's Hospital, 1056 E. 19th Ave., Denver, Co 80218-1088** EOE M/F

(NW4353)A

UNIVERSITY OF MANCHESTER DEPARTMENT OF CELL AND STRUCTURAL BIOLOGY

POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited to join a large well equipped group working in the general area of regulation of gene expression in vertebrate embryos. This post will involve the study of homeobox gene expression and function in mouse embryos. Applicants should have a Ph.D. in a biological sciences subject and, although not essential experience in molecular biology, embryology or transgenic animals. The post is available immediately. Initial salary on range £10,458-£12,381 p.a. according to qualifications and experience. Applications with names of two referees by November 2nd, 1989 to **Dr Paul T. Sharpe, Department of Cell and Structural Biology, the University, Manchester M13 9PT** from whom further details may be obtained (061 275 5253). *The University is an equal opportunities employer.* (1746)A

DEVELOPMENTAL NEUROBIOLOGIST

The David Mahoney Institute of Neurological Sciences (INS) of the University of Pennsylvania is recruiting a Developmental Neurobiologist at the rank of Assistant or Associate Professor. We are particularly interested in people working at the molecular or cellular level, either in genetics or in other aspects of nervous system development. The INS has over 100 members and already has several excellent laboratories working on cellular, molecular and biochemical aspects of neural development and regeneration. Applicants should send their curricula vitae and names and addresses of three references to: **Michael E. Selzer, MD/PhD, Department of Neurology Hospital of the U of Penn., 3400 Spruce Street, Philadelphia, PA 19104-4283.** Equal Opportunity/Affirmative Action Employer. (NW4334)A

Research Pharmacologist

Syntex, an international leader in the pharmaceutical and health care industries, has an opening in our Pharmacology Institute for a Research Pharmacologist.

Use your strong background in classical theory i.e., knowledge of pharmacological analysis of potency, affinity and receptor reserve in a position requiring considerable leadership ability in both basic research and drug discovery programs.

You should have experience in a wide range of isolated tissue bioassays including assays routinely employed in the muscarinic, serotoninergic and prostanoid receptor areas. Additional experience in the use of cell culture and radioligand binding would be an advantage. Requirements include a PhD in Pharmacology with 2 or more years of relevant postdoctoral experience.

Syntex offers outstanding research facilities and a competitive compensation/relocation package, in a campus-like environment on the San Francisco Peninsula. For immediate consideration, please send your resume to: Syntex, Professional Staffing, Dept.KH/NA, 3401 Hillview Avenue, Palo Alto, CA 94304. Syntex is an equal opportunity employer.

UNIVERSITÉ LAVAL

RESEARCH CHAIR

in Collaboration with NSERC and Semex Canada

The Natural Sciences and Engineering Research Council of Canada in collaboration with Semex Canada agreed to sponsor an industrial chair program at Laval University. The position is offered in the department of Animal Sciences with extensive collaboration possibilities with the Ontogeny-Reproduction and the Molecular-Endocrinology research units at the Laval University Hospital Research Center. This new position will complete the existing group in animal reproduction where many aspects of embryonic and female physiology are currently investigated. The principal area of research will be the bovine spermatozoa including various aspects of fertilization, sperm biochemistry and related new biotechnologies. The chair will be funded for an initial period of 5 years with possibility of a renewal for a second term. The position offered is a tenure tract position with immediate permanency or possibility of a full professor status depending on the candidate's experience. There is *no* undergraduate teaching responsibilities and extensive personal and material support are included in this position. A large operating grant is also automatically awarded. This potential candidate should be a researcher of international status approaching the most productive period of his/her career. He or she should have the necessary qualifications to hold the rank of full professor and be a recognized expert in his/her field. Both NSERC and Semex Canada approval will be required for the candidate to be accepted by the University. The position will remain open until a suitable candidate is found.

Please send a complete Curriculum Vitae and a letter of application to:

Marc-André Sirard,
Industrial Chair Committee,
Dept. Zootëchnie,
Université Laval,
Québec, QC, Canada, G1K 7P4.
Fax: 418–654–9053.

(NW4359)A

UNIVERSITY OF DURHAM
Department of Archaeology

CHAIR OF ARCHAEOLOGY

Applications are invited for the Chair of Archaeology at Durham from candidates with an established international reputation in any branch of the discipline. The successful candidate will be expected to provide academic and administrative leadership for the Department which is recognised as one of the principal centres for archaeological research and teaching in the British Isles, and is set to expand further following the recent UFC review of archaeology.

The appointment arises from the retirement of Professor Rosemary Cramp CBE and is tenable from 1st August 1990 or such date as may be arranged.

Further particulars may be obtained from the **Registrar and Secretary (P), University of Durham, Old Shire Hall, Durham DH1 3HP,** to whom applications (twelve copies) including the names of three referees, should be submitted not later than Thursday 30 November 1989. (Candidates outside the British Isles need submit one copy only.)

POSTDOCTORAL POSITION

Molecular Genetics/ Circadian Rhythms

We use classical and molecular genetics to the molecular mechanism of the circadian clock (*Nature* **339**, 558–562, June 15, 1989 cover article), study (*Science* **243**, 385–388, 1989). Experience with genetics, biochemistry, and/or recombinant DNA is essential. Please send CV and the names of three references to Prof. Jay C. Dunlap, Dept. of Biochemistry, Dartmouth Medical School, Hanover, NH 03756. (NW4356)A

MRC PROTEIN PHOSPHORYLATION GROUP

BIOCHEMISTRY DEPARTMENT, UNIVERSITY OF DUNDEE

POSTDOCTORAL POSITIONS

Following expansion of Professor Philip Cohen's research programme by the Medical Research Council, applications are invited for post-doctoral positions from scientists with experience in protein chemistry, enzymology, cellular regulation and immunocytochemistry. A major aspect of the research is concerned with the structure and regulation of protein phosphatases. Recent work within the Group has demonstrated that these enzymes play key roles in cell division and in tumour suppression, and several new phosphatase genes have been identified. Novel mechanisms of control have also been identified that involve interaction of the phosphatases with "targetting subunits". The positions are available immediately, but candidates wishing to start at any time up to Summer 1990 will be considered. The appointments are for three or five years in the first instance, and will be made at an appropriate point on the University Grade 1A scale, depending on qualifications and experience.

The Department is one of the most highy funded in Britain and offers outstanding research facilities and working environment. Housing and accommodation costs are among the lowest in the UK and access to outdoor recreational facilities is unrivalled.

Applications containing a full curriculum vitae and the names and addresses of three referees should be sent to **Professor Philip Cohen, FRS, FRSE, Department of Biochemistry, The University, Dundee, DD1 4HN, Tayside, Scotland** as soon as possible. Informal enquiries by telephone to Philip Cohen (0382 23181—Ext. 4238). Please quote Ref: EST/439/89/N. (1786)A

UNIVERSITY OF NORTH CAROLINA at Chapel Hill

The Department of Chemistry

invites applications for

Assistant

or untenured

Associate

tenure track

Professorships

for several open positions. Areas of specialization are open but special consideration will be given to biological, organic and physical chemists. Applicants should send a curriculum vitae and a brief statement of research plans and should arrange for the submission of four letters of recommendation. Review of applications will begin on November 15, 1989. Address applications to: **Eugene A. Irene, Chairman of the Search Committee, Department of Chemistry CB# 3290, University of North Carolina, Chapel Hill, NC 27599-3290.** *UNC-CH is an EO/AA Employer.* (NW4321)A

LECTURERS IN PHARMACOLOGY, BIOCHEMISTRY, MICROBIOLOGY, AND CELL BIOLOGY

St. George's University School of Medicine is a small private school dedicated to excellence in international education. Our program is recognized by the General Medical Council for limited registration, and is approved for purposes of clinical training by the states of New York, New Jersey, and California.

At present we are seeking additional lecturers. One year initial contract, renewable. Experience teaching medical students is desirable. Applications will be considered from experienced lecturers taking early retirement. Level of appointment and salary are negotiable.

We are also seeking Laboratory Demonstrators in Histology and Pathology.

Send C.V. and teaching references to Dr. David Louis Brown, St. George's University, School of Medicine, P.O. Box 7, St. George's, Grenada, West Indies. (W6536)A

University of Saskatchewan

Department of Geological Sciences

ICP-MS Lab Supervisor

The Department of Geological Sciences at the University of Saskatchewan is seeking a highly qualified person to supervise an ICP-MS laboratory, with laser ablation. The candidate should preferably have a Ph.D. in chemistry or geochemistry, and hands-on experience with all aspects of ICP-MS operations. In addition to supervising the operation of the laboratory, the candidate would train graduate students and visitors in use of the ICP-MS, assist faculty with conducting analyses, develop new chemical separation and analytical techniques, and participate in joint research. Salary will be commensurate with qualifications and experience. In accordance with Canadian Immigration guidelines, qualified Canadian citizens and permanent residents are especially encouraged to apply.

Qualified candidates should contact:

Drs. R. Kerrich or T.K. Kyser

Department of Geological Sciences

University of Saskatchewan

Saskatoon, Saskatchewan S7N 0W0

Telephone: (306) 966-5719/5697/5683

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

CENTERS FOR DISEASE CONTROL
CENTER FOR INFECTIOUS DISEASES
DIVISION OF HOST FACTORS
MEDICAL OFFICER (PATHOLOGIST)

A position is available to study molecular pathologic mechanisms for laboratory and epidemiologic investigations of leukemias, tumors, and other abnormal cell growths. Emphasis is on detection of infectious agents as possible etiologic agents in neoplasia. Experience is necessary in studies related to myeloperoxidase gene expression and monoclonal antibody production to myeloperoxidase. This position is with Bruce Evatt, M.D., Director, Division of Host Factors. Minimum qualifications include a medical degree or equivalent, Board-certification in anatomic pathology, experience in molecular research in myeloperoxidase gene expression, and experience in the conduct of independent and collaborative investigations. The position may be filled either in the competitive Civil Service or in the Public Health Service Commissioned Corps. The salary range is $50,137 to $63,553. Candidate should send curriculum vitae and the names and addresses of three references by November 15, 1989, to:

Mr. William V. Nelson
Personnel Management Office, Bldg 1/Room 1058, MS D01
Centers for Disease Control
1600 Clifton Road, N.E.
Atlanta, Georgia 30333

CDC is an Equal Opportunity Employer and provides a smoke-free work environment. (NW4329)A

CARBOHYDRATE SCIENCE FACULTY

The University of Georgia COMPLEX CARBOHYDRATE RESEARCH CENTER (CCRC), currently with 90 members (faculty, staff, and students) will hire three tenure-track faculty this year. The CCRC, particularly well-equipped and well-organized for collaborative and interdisciplinary research, has recently occupied its own, new 40,000 sq ft building. Appointments will normally be at assistant professor level, but one senior distinguished professorship may be filled. Appointees expected to develop own research team in fundamental carbohydrate science. The CCRC particularly seeks carbohydrate chemists, and molecular biologists with demonstrated research ability in utilizing recombinant genetic techniques in the study of complex carbohydrates of plants, animals, or microbes. Individuals with interests in other areas of carbohydrate science are encouraged to apply. Applications received by November 1, 1989 considered then; later applications considered as received. Send letter of application, proposed research, complete c.v to: **Drs Peter Albersheim or Alan Darvill, Directors, Complex Carbohydrate Research Center, The University of Georgia, 220 Riverbend Road, Athens, GA 30602, USA.** An AA/EEO institution. (NW4325)A

The Swiss Institute of Allergy and Asthma Research
is seeking a

Postdoctoral Research Fellow

with experience in immunology and cell biology preferably in the field of IgE antibody regulation. Specific areas of research include the establishment of human T cell clones, their immunological, biochemical and genetical characterization and the study of cellular interactions.

Applications, including a detailed curriculum vitae and naming academic referees, should be sent to **Dr. Kurt Blaser, PhD, SIAF, Obere Strasse 22, CH-7270 Davos, Switzerland.** (W6547)A

Neuroanatomist/ Experimental Neuropathologist

Independent research faculty position in the Neuroscience Program at the Maryland Psychiatric Research Center. Experience with modern neuroanatomical techniques required, interest in psychiatric disorders desirable. New EM faculty and generous start-up provided.

Please send CV, a brief outline of research plans and names of at least three references to **Robert Schwarcz, Ph.D. Maryland Psychiatric Research Centre, P.O. Box 21247, Baltimore, Maryland 21228.** (NW4347)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
BIOCHEMISTS/BIOCHEMICAL PHARMACOLOGISTS
POST-DOCTORAL RESEARCH OFFICERS
PRE-DOCTORAL RESEARCH OFFICERS

We are seeking suitably qualified applicants for the above posts, tenable for three years. Successful applicants will join a well-funded multi-disciplinary group, working in the Department of Clinical Pharmacology, studying the formation, disposition and enzymatic activation of carcinogenic aromatic amines produced in food during cooking. The aim of this research is to assess the risk to man posed by these compounds in the diet, and to evaluate current methods of extrapolating carcinogenicity data from animals to man. Studies will involve a variety of techniques, include 32p post-labelling, antibody production and sophisticated analytical methodology.

Preference will be given to applicants with experience in genotoxicity, biomonitoring or analytical chemistry, although experience in other relevant areas of biochemistry, biochemical pharmacology or biochemical toxicology would be acceptable. Applicants should hold a PhD for the post-doctoral positions, or honours BSc, or equivalent, for the other posts. Suitable appointees to the post of Research Officer may be considered for registration for a higher degree.

Salaries on scale Range 1A and 1B.

Informal enquiries may be made to Professor D S Davies (01–740 3220), Dr A R Boobis (01–740 3221) or Dr N J Gooderham (01–740 3220).

Application forms and further particulars may be obtained from the **Personnel Office, Royal Postgraduate Medical School, Du Cane Road, London W12 0NN** quoting ref: AEX3. (1731)A

The Department seeks qualified applicants for a tenure track position at the

Assistant Professor

level in Mathematical Biology starting August 21, 1990. There will be start up funds available for the successful applicant. We will begin the interview process January 15, 1990. Women and minorities are encouraged to apply. Iowa State University is an Affirmative Action/Equal Opportunity Employer. Applications should be sent to: **Howard A. Levine, Chair, Department of Mathematics, Iowa State University, Ames, Iowa 50011.** (NW4323)A

Columbia University

Position for POSTDOCTORAL HEMATOLOGY RESEARCH FELLOW (M.D. or Ph.D.) interested in gene transfer and gene therapy. Ongoing project in molecular and cellular biology transferring human globin genes in retroviral vectors into mice. Tissue culture and molecular biology techniques currently used will be available to applicant. Previous experience in molecular biology preferred. Opportunity for career advancement.

Send résumé to: **Dr. Arthur Bank, Columbia University, HHSC 1602, 701 West 168th Street, New York, NY 10032.** (NW4351)A

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

ROCKEFELLER FOUNDATION BIOTECHNOLOGY CAREER FELLOWSHIPS

The Rockefeller Foundation announces a program of career development fellowships designed to enable scientists from developing countries, trained at outstanding centers for advanced research on biotechnology, to continue to work at those or other institutions for three months each year, over a period of at least three years, conducting advanced research and keeping abreast of new developments in their fields. The program will focus upon the development and application of advances in molecular and cellular biology and immunology relevant to agriculture, health, and reproductive biology.

Funding will be shared between the Foundation and the host laboratory, with the Foundation providing travel and per diem support. It is hoped that the fellowships will encourage the establishment of ongoing working relationships between outstanding younger scientists working at third world institutions, and research teams at advanced laboratories.

Applicants to this program should have at least Ph.D.- or M.D.-level training, a proven record of scientific productivity, and a permanent position at a research or teaching institution in their home country. A written project proposal must be developed and submitted jointly by the candidate and the laboratory sponsor.

Information about application procedures can be obtained by writing to **Biotechnology Career Fellowships, Fellowship Office, Rockefeller Foundation, 1133 Avenue of the Americas, New York, New York 10036, USA.**

(NW3382)E

POSTDOCTORAL FELLOWSHIPS WOODS HOLE OCEANOGRAPHIC INSTITUTION

Ocean Science and Engineering

Applications are invited from new or recent doctorates in science or engineering with interests in physical oceanography, meteorology, marine chemistry, marine geology and geophysics, biological oceanography, or oceanographic engineering. Recipients of awards are selected on a competitive basis, with primary emphasis placed on a research promise.

Marine Policy and Ocean Management

Research fellowships are offered to individuals in the social sciences, law, the humanities, or natural sciences to apply their training to problems or issues that involve the use of the oceans. Presently research follows thematic areas such as Marine Science and Public Policy; Ocean Jurisdictions, Law of the Sea, and International Relations; Development and Management of Ocean Resources; and Areawide Planning and Management. Emphasis is placed on the economics of ocean space and on the role of science in governmental and industrial decision making. Topics of special current interest include marine biological diversity, the quality of marine habitats and marine reserves, and the impacts of sea-level change. Other research interests are also appropriate.

Fellowships are rewarded for one year with a stipend of $30,500 plus group health insurance and a modest research budget. Recipients are encouraged to pursue their own research interests independently or in association with resident staff. Completed applications must be received by January 15, 1990 for 1990-91 awards. Awards will be announced in March. Write for application forms to: Dean of Graduate Studies, P.O. Box N, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543

Equal Opportunity/Affirmative Action Institution

(NW4337)E

UNIVERSITY OF ABERDEEN
DEPARTMENT OF ZOOLOGY
AND
ROTHAMSTED EXPERIMENTAL STATION, HARPENDEN, HERTS

POSTDOCTORAL FELLOWSHIP
PHEROMONAL CONTROL OF BITING FLIES

Applications are invited for a Postdoctoral Research Position funded for 3 years by the AFRC Link programme, to work with Professor W Mordue, Dr A J Mordue, Dr M R Young (Aberdeen) and Dr L J Wadhams (IACR, Rothamsted) on a project directed towards a pheromonal approach to the control of Scottish midges (*Culicoides*).

The project will involve field identification of suitable species, their collection and mass rearing; analysis of their mating behaviour and the role played by sex and aggregation pheromones; extraction and identification of the pheromones involved and their use in pilot field trials to attract and control the midges.

Applicants should have experience in the physiology and ecology of insects. Knowledge of electrophysiological/pheromonal techniques would be an advantage but is not essential.

Appointments will be made on the RA IA Scale. Preferred starting date is 1 January 1990. Further particulars from the Personnel Office (tel 0224 273500). Applications by letter with full CV including the names of three referees to the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX,** by *27 October* quoting reference number LW/056. (1768)E

THE OPEN UNIVERSITY
FACULTY OF SCIENCE

Postdoctoral Research Fellow in Cellular Mechanisms of Memory

Applications are invited from candidates with a good background in neurochemical techniques for a SERC-funded postdoctoral fellowship in cellular mechanisms of memory. The research will be carried out in the Biology Department at the Open University campus, Milton Keynes, under the supervision of Professor Steven Rose and Dr Michael Steward of the University's Brain and Behaviour Research Group. The project concerns the role of neurotransmitter release, protein phosphorylation and receptor-second messenger ion channel coupling in memory consolidation processes in the young chick.

Applicants should have a PhD degree in a relevant subject area.

The post is available immediately for a period of three years. Salary will be either on the Grade 1A scale for Research and Analogous Staff (£10,458-£16,665 p.a.), or the Grade II scale (£15,372-£20,469 p.a.), according to age and experience.

Application forms and further particulars are available from **Ann Hall (7107/1), Faculty of Science, The Open University, Walton Hall, Milton Keynes MK7 6AA,** or telephone Milton Keynes (0908) 655938: there is a 24-hour answering service on 653868.

Candidates may also wish to contact Professor Rose on (0908) 652125 to discuss the project.

Closing date for applications: 23rd October.

Equal Opportunity is University Policy. (1760)E

POSTDOCTORAL FELLOWSHIP

involving instrumentation and methods development related to increasing sensitivity of protein microsequencing. Background in biochemistry or protein chemistry preferred. Experience in protein sequencing, HPLC, and electrophoresis desirable. Send curriculum vitae and three letters of reference to: **Dr. Leroy Hood, California Institute of Technology, Division of Biology 147-75, Pasadena, CA 91125.** *EOE/AA* (NW4354)E

University of Nottingham
Department of
Pharmaceutical Sciences

Post Doctoral Fellowship

Applications are invited for the above Fellowship to be funded by the WHO (Transdisease Vaccinology) for 2 years from October 1989. This is a collaborative research project between the above Department (Head of Department, Prof S.S. Davis) and Prof S.J. Challacombe at the Department of Oral Medicine and Pathology at Guy's Hospital, London and involves the use of colloidal carriers as antigen delivery systems for oral immunisation against intestinal pathogens. Experience of pharmaceutical formulation would be an advantage, as too would be immunological expertise.

Starting salary will be within the 1A scale according to age and experience £10,458–£16,665. Applications, including a CV and names of two referees should be sent in duplicate to **Dr D. O'Hagan, Department of Pharmaceutical Sciences, University of Nottingham, Nottingham, NG7 2RD.** For further details contact Dr O'Hagan 0602–484848 (Ext. 3228). (1747)E

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOCHEMISTRY

Postdoctoral Research Fellow

Applications are invited for a Postdoctoral Fellowship financed by an MRC grant awarded to Dr C D O'Connor, to study the structure and mechanism of action of a human bactericidal protein from polymorphonuclear leucocytes, using genetic and biochemical techniques. The appointment is for up to three years, with a starting salary from £10,458 per annum on the 1A scale for research and analogous staff.

Applications, including curriculum vitae and the names, addresses and telephone numbers of three referees, should be sent to **Dr C D O'Connor, Department of Biochemistry, University of Southampton, Bassett Crescent East, Southampton, S09 3TU,** no later than 26 October 1989. *Please quote reference number: 77/JAD/jm.* (1748)E

UNIVERSITY OF DURHAM
RESEARCH FOUNDATION

ADDISON WHEELER FELLOWSHIP

Applications are invited for an Addison Wheeler Fellowship enable for five years from as soon as possible. The Fellowships were established to encourage "efforts for increased knowledge of Man and his physical make-up so as to enable him to make better use of his life here on earth". It is assumed that candidates will be working in the Life Sciences, but candidates in other fields who feel that their research meets the aims of the Wheeler Fellowships are encouraged to apply.

Candidates must be under 28 years of age on taking up the Fellowship. Salary on Research Grade 1A, currently £10,458-£16,665 per annum.

Applications (three copies) including details of the proposed field of study and naming three referees, should be sent by 31 October 1989 to the **Deputy Secretary, Old Shire Hall, Durham DH1 3HP,** from whom further particulars may be obtained. (1761)E

Wayne State University

PREDOCTORAL FELLOWSHIPS

Wayne State University

Positions are available for graduate study leading to a Ph.D. in Physiology. An annual stipend of $11,500 plus tuition waiver and medical insurance are provided for qualified students.

The department has strong research programs in molecular, cellular and systems physiology. Specific areas of interest include endocrinology, membrane transport, neurosciences, protein structure and function, cardiovascular and renal physiology.

For more information, write to: **Dr. Lowell McCoy, Graduate Officer, Department of Physiology, Wayne State University School of Medicine, 540 E. Canfield, Detroit, MI 48201 USA.** *WSU is an Equal Opportunity/Affirmative Action employer.* (NW4335)E

UNIVERSITY OF COLORADO
VISITING FACULTY AND
POSTDOCTORAL FELLOWSHIPS (1990–91)

FOR RESEARCH IN

● atmospheric chemistry ● atmospheric and climate dynamics ● environmental chemistry and biology ● environmental measurements and instrumentation ● global change ● remote sensing

at the Cooperative Institute for Research in Environmental Sciences (CIRES).

Five competitive fellowships will be awarded to recent Ph.D. recipients and to senior scientists, including faculty on sabbatical leave. Stipends average $26,500 for twelve months. Appointments can begin at any time during the year. Selection of awardees is made in part on the likelihood of active interaction with CIRES scientists. Senior CIRES-affiliated scientists working in these fields include James Avery, Susan Avery, Ben Balsley, Roger Barry, John Birks, Maurice Blackmon, William Bowman, Henry Diaz, R. Ray Fall, Lang Farmer, Fred Fehsenfeld, Alexander Goetz, Vijay Gupta, Howard Hanson, Michael Hardesty, William Hay, Murray Johnston, William Lewis, Uwe Radok, Colin Ramage, George Reid, Russ Schnell, and Robert Sievers. Candidates are encouraged to contact one or more of the senior investigators as they are preparing their proposals. Apply to **Prof. R. Sievers, Director of CIRES, Visiting Fellows Program, CB 216, University of Colorado, Boulder, CO 80309.** Include résumé, publications list, and brief description of proposed research. Also request that three persons familiar with your qualifications send letters of recommendation. Junior applicants must submit undergraduate and graduate transcripts. First consideration will be given to applications received by December 1. Final application deadline is February 15. The University of Colorado at Boulder has a strong institutional commitment to the principle of diversity. In that spirit, we are particularly interested in receiving applications from a broad spectrum of people, including women, members of ethnic minorities, and disabled individuals. (NW4318)E

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

SHORT TERM FELLOWSHIPS

in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from **Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.** (W5706)E

STUDENTSHIPS

THE UNIVERSITY OF SHEFFIELD
Department of Obstetrics and Gynaecology

RESEARCH STUDENTSHIP

Applications are invited for the above studentship to study sperm transport in the human female reproductive tract. The appointee will register for a PhD for three years and will be required to have a first class or an upper second class honours degree in Biological Sciences. The post is supported by the University of Sheffield and the Infertility Research Trust.

Informal enquiries to **Dr C L R Barratt (0742-766333, ext 343/342), University Department of Obstetrics & Gynaecology, Jessop Hospital for Women, Sheffield S3 7RE** to whom applications, including a CV and the names/addresses of three referees should be submitted by 1 November 1989. Ref. MAP199/G. (1755)F

FELLOWSHIPS continued

on pages 26 & 27

ASSISTANTSHIPS

UNIVERSITY OF BRISTOL
Department of Theoretical Chemistry

Post-doctoral Research Assistantship

A post-doctoral research assistantship, funded by SERC, is available in the research group of Dr J Gerratt for a period of three years, starting January 1st 1990, for theoretical work on the spin-coupled VB description of molecular electronic structure. The project covers several topics, including the development of codes for a non-orthogonal many-body perturbation theory and its use in the accurate determination of potential surfaces of organic reactions, and the calculation of spin-dependent properties of molecules. The appointment will be made at the lower end of the RA1A scale (£10458-£12879).

Informal enquiries can be made to Dr Gerratt, on Bristol (0272) 303030 ext. 4715 or 4270.

For further details telephone Bristol 303136 (ansaphone after 5.00 p.m.) or write to the **Personnel Office, Senate House, Bristol BS8 1TH.** Please quote reference A758.

We are an equal opportunity employer. (1750)P

UNIVERSITY OF BRISTOL

RESEARCH IN BEHAVIOURAL ECOLOGY

Applications are invited for a SERC-funded post-doctoral research assistantship to work with Dr J M McNamara in the Department of Mathematics. The post is to investigate functional explanations of the daily and annual routines of animals. Candidates should either have a background in Behavioural Ecology or possess modelling and computer skills, or preferably both.

The appointment is for 3 years and will be on the Research 1A scale (£10,458-£16,665) depending on age, qualifications etc.

Informal enquiries can be made to Dr McNamara on Bristol (0272) 303581 or 303030 ext. 4347.

For further details telephone Bristol 303136 (ansaphone after 5.00 p.m.) or write to the **Personnel Office, Senate House, Bristol BS8 1TH.** Please quote reference A767. (1753)P

PROPOSALS

EC CONCERTED RESEARCH PROGRAMME EUROPEAN VACCINE AGAINST AIDS (EVA)

Call for Proposals for Collaboration

The objective of this European programme is to assist and support European efforts towards the development of vaccines against AIDS through the provision of various high quality laboratory reagents for studies leading to vaccine development.

Proposals identifying research reagents needed in vaccine development projects are requested. Those aimed at developing new reagents will also be considered.

The proposals should give scientific reasons for the projects and detailed characteristics that the requested materials should have. Organisations or individuals from EC or COST countries or from those with special arrangements with the EC wishing to respond to this request should contact:

Dr Harvey Holmes, NIBSC,
South Mimms, Potters Bar
Herts EN6 3QG,
United Kingdom.
Tel: +44 707 54753
Fax: +44 707 46730.

Application deadline is the 31st October 1989. (1758)X

STA FELLOWSHIP PROGRAM

1. Purpose

The purpose of this program is to promote the international exchange of researchers by providing fellowships to foreign researchers in the science and technology fields (excluding those concerned exclusively with the humanities).

2. Outline of the Program

Fellowship awardees fall into two categories: (1) those recommended by their own governments and (2) those recommended by Japanese host institutes.

(1) Numbers of awardees: 130 for FY 1989 (100 for FY 1988).

(2) Qualifications:

① Possession of a doctoral degree in a scientific or engineering field, or an equivalent qualification.

② Age under 35, in principle.

③ Having sufficient language ability to be able to pursue research in Japan. Japanese ability is preferable, but in most cases English ability is sufficient. With the host institute's agreement, other languages may also suffice.

3. Tenure and field of research:

Tenure is between 6 months and 2 years, to be decided through negotiation between the candidate and the host institute.

The field of research is also decided through negotiation between the candidate and the host institute. The results of research work produced during the tenure will be subject to the regulations of the host institute.

4. Fellowship awards:

The following items will be provided to the Fellowship awardees as tax-free allowances.

① Round-trip airline ticket (economy class).

② Living allowance: ¥ 270,000 per month, (approx U.S.$2,000).

③ Family allowance: ¥ 50,000 per month (approx U.S.$370).

④ Housing: ¥ 100,000 maximum per month (approx. U.S.$740) may be paid as housing allowance; any shortfall is to be borne by the awardee.

⑤ Relocation allowance for moving from overseas to Japan: ¥ 200,000 (approx. U.S.$1,500).

⑥ Travel allowance (in Japan for business trips regarding research activities): ¥ 100,000 maximum per year (approx. U.S.$740).

5. Host Institutes

Host institutes comprise national laboratories (excluding universities and laboratories affiliated with universities), public (semi-government) corporations, and non-profit organizations.

JRDC is to undertake the implementation of STA Fellowship Program: Japan International Science and Technology Exchange center (JISTEC) is responsible from the receipt of the application from candidates and liaising with them.

SUPPORT PROGRAMS

In order to help foreign researchers, who are engaging in research or exchanging information at Japanese research institutes, and their families to make a smooth transition to research and enjoy their everyday life, JRDC is to promote support programs such as assistance to find houses, supply of information on living in Japan, counselling for daily life and Japanese language lessons.

RESEARCH INFORMATION PROGRAM

For foreign research institutes and researchers who are seeking opportunities for research exchange with Japanese counterparts, information focused on Japanese research activities will be provided.

★ IF YOU ARE INTERESTED IN THE ABOVE PROGRAMS (APART FROM THE STA FELLOWSHIP PROGRAM) PLEASE CONTACT:

Department of International Research Exchanges
Research Development Corporation of Japan (JRDC)
5-2, Nagata-cho, 2 Cho-me, Chiyoda-ku, Tokyo 100, Japan. TEL: 03-507-3024 or 3025; FAX: 03-581-1486

★ IF YOU ARE INTERESTED IN THE STA FELLOWSHIP, PLEASE CONTACT:

Japan International Science and Technology Exchange Center (JISTEC)
Port One Building 6F, 1-7-6, Minato-machi, Tsuchiura City, Ibaraki Pref. 300, Japan
TEL: 0298-24-3355; FAX: 0298-24-3214

ARE YOU LOOKING FOR OPPORTUNITY IN RESEARCH?

Research Development Corporation of Japan (JRDC), established in 1961, is a government owned organization which operates under the Science and Technology Agency (STA).

The objective of JRDC is to effectively carry out the development of new technology, engage in the basic research deemed to contribute to the creation of new technology, and to disseminate the outcome of these developments and basic research.

In addition to these activities, JRDC is to undertake the promotion of the International Research Exchange Program, consisting of 1) The International Joint Research Program, 2) The STA Fellowship Program, 3) The Support Programs, and 4) The Research Information Program.

INTERNATIONAL JOINT RESEARCH PROGRAM

1. Purpose

This program shall work toward the following purposes through joint research supported by JRDC and foreign research organizations:

(1) Develop the seeds of innovative science and technology by integrating the advanced research activities of Japan and of other countries concerned; (2) Contribute internationally by fostering broad public dissemination of the knowledge gained from such research; and (3) Promote research exchange between Japan and other countries, thereby promoting science and technology.

2. Outline of the Program

Non-Japanese research organizations wishing to conduct joint research projects with JRDC shall carry out such research with JRDC within the following framework, and shall share, on an equitable basis, personnel and all expenses and costs necessary for the implementation of the research.

(1) Research fields and themes

Research themes are to be sought in basic research fields including new materials, life sciences and electronics. Themes should be directed toward creating new concepts that will become the seeds of innovative science and technology development. These research themes must be those for which consent is obtained from both JRDC and its counterpart.

(2) Framework for a Joint Research Project (Standard model for joint research)

① Term: 5 years (Flexible: 3 to 7 years)

② Budget: ¥ 2 to ¥ 3 billion (approx U.S.$14–21 mil.) [Each side bears ¥ 1 to 1.5 billion]

③ Site:
A research site shall be established at a suitable university or a research institute.

④ Researchers:
Both JRDC and its foreign counterpart concerned may select their respective researchers from academia, industry and government.

i) Research directors: 2 (one from each side)

ii) Researchers: 15 to 20 in total for both countries.

⑤ Patent rights:
The patent rights resulting from the joint research should be jointly owned on an equitable basis.

GRANTS & SCHOLARSHIPS

American Museum of Natural History

FELLOWSHIPS AND GRANTS

FELLOWSHIPS — American Museum of Natural History Research/Museum Fellowships are available to postdoctoral researchers and established scholars starting in summer and fall 1990. Areas include vertebrate and invertebrate zoology, paleozoology, anthropology, mineral sciences, and the field of museum education as it relates to natural history museums or planetariums. Deadline for applications, including Chapman Fellowships (ornithology), is January 15, 1990.

GRANTS — American Museum of Natural History Grants are available to advanced predoctoral candidates and recent postdoctoral researchers in the fields of zoology and paleontology. Awards range from $200 – $1,000. Deadline dates vary for each Grant Program:

* Frank M. Chapman (ornithology) — January 15, 1990.
* Theodore Roosevelt (N.A. fauna) — February 15, 1990.
* Lerner-Gray (marine) — March 15, 1990.

Request information booklet and applications from the **Office of Grants and Fellowships, Department G, American Museum of Natural History, Central Park West at 79th Street, New York, New York 10024.**

(NW4340)H

COURSES & CONFERENCES continued

MOLECULAR ENDOCRINOLOGY AND TECHNIQUES FOR HORMONE ACTION

February 19-23, 1990

This course will consist of lectures in methodology with comprehensive syllabus covering receptors, gene transcription, mRNA and protein synthesis, recombinant DNA, protein hormones and cyclic nucleotides.

Co-directors: M. R. Hughes and B. W. O'Malley.

Fee: $365 ($245: fellows and students).

For further information contact: **Bonnie Cuthbert, Department of Cell Biology, Baylor College of Medicine (713)-798-6200.**

DEADLINE — February 2, 1990. (NW4144)C

TOOLS FOR A NEW BIOLOGY

A one-week course focusing on an integrated, multi-disciplinary approach to the development of procedures for the separation, detection, and micro-characterization of complex mixtures of proteins and nucleic acids. Includes the role of novel computer hardware/software in the analysis of biological data. Sponsored by the NSF Center for Biotechnology. Director: Leroy Hood. For information contact: **Sue Lewis, Caltech, Div. Biology, 147-75, Pasadena, CA 91125. Phone: (818) 356-8390 or Fax (818) 793-4627.** (NW4364)C

THE ROYAL SOCIETY
GOVERNMENT GRANTS FOR OVERSEAS FIELD RESEARCH

Applications for Overseas Field Research grants for 1990 are invited to be made not later than 15 December 1989 on forms of application to be obtained from the Executive Secretary of the Royal Society, 6 Carlton House Terrace, London SW1Y 5AG (ref: LUM). Decisions on applications will be given in March 1990.

Grants may be made to promote and support scientific research involving field work overseas or work at sea; but not for payment of stipends or to aid scientific publications. Grants will normally not exceed £10,000.

Applicants must be British Citizens ordinarily resident in the United Kingdom and be of post-doctoral or equivalent status. (1740)H

OVER HALF A MILLION SCIENTISTS ARE LOOKING AT THIS SPACE.

nature

SHOULDN'T YOU BE FILLING IT?

CALL FOR
POSTERS AND SHORT REPORTS

"Advances in Gene Technology: The Molecular Basis of Immune Diseases"

January 21-26, 1990

The major gene technology conference of 1990 - **THE MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA** is announcing its call for poster presentations that will appear in the conference proceedings as Short Reports and will be published by the ICSU Press and IRL Press.

Poster sessions are scheduled for January 22,23, and 24, 1990 at which time you may present your reports on 4' high x 6' wide corkboards provided for the occasion. The Short Report is the permanent record of your poster.

To have your Short Report considered for acceptance, you must be registered for the Symposia, and your Short Report must be received no later than **November 1, 1989**. Notification of acceptance will be sent within three weeks of the closing deadline.

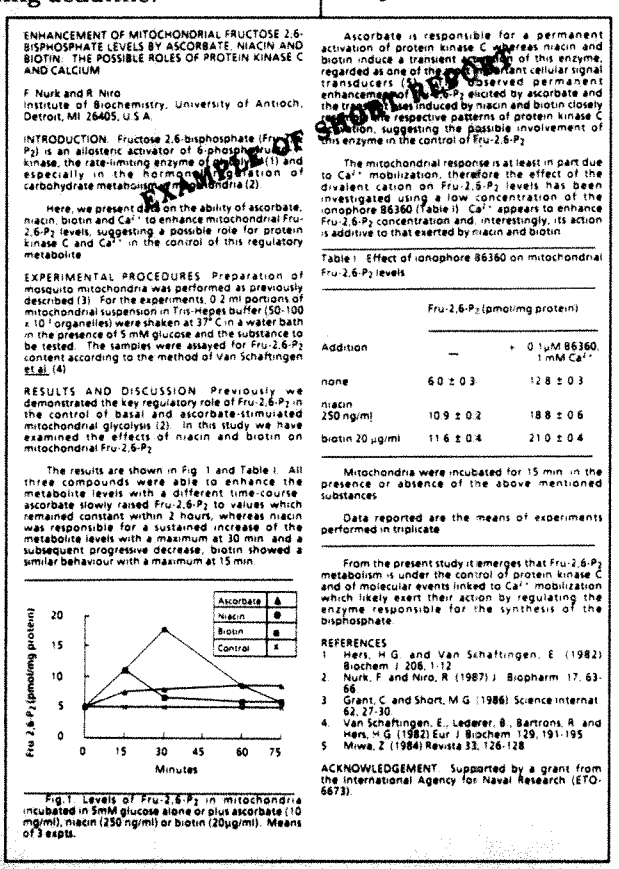
GUIDELINES FOR PREPARING SHORT REPORTS

To give your report the best chance of being accepted by the Symposia, try to follow these simple guidelines:

Legibility. The type style must be letter quality. Neatness counts.

Technical Specifications. Use the grid paper or type on two A4 or legal size sheets within a grid of 10 cm. wide and 28 cm. deep. Do not draw lines around your Report. Type size - 12 pitch. Single space. Number the pages in pencil on the reverse.

Length of Report. Two columns (2 grids of 10 x 28 cm) equals one page. **You must occupy two (2) columns in order to be considered for publication.** Anything under or over will automatically be rejected.



Headings. Capitalize headings for major sections either by topic, or organizationally, e.g. INTRODUCTION, DISCUSSION, REFERENCES.

Subheadings. Use capitals for initials and underline the phrase.

References. Cite these by number in the order in which they appear in the text. Collect the bibliography into a section at the end. **A bibliography is essential.**

Acknowledgements. These should appear last.

Make certain your work is represented at this important event. **Mail your UNFOLDED** Short Report to: MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, P.O. Box 016129, Miami, FL 33101, USA. (If using a courier service, to MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, Room 6054, Medical Research Building, University of Miami School of Medicine, 1600 NW 10th Ave., Miami, FL 33136, USA.)

ENHANCEMENT OF MITOCHONDRIAL FRUCTOSE 2,6-BISPHOSPHATE LEVELS BY ASCORBATE, NIACIN AND BIOTIN. THE POSSIBLE ROLES OF PROTEIN KINASE C AND CALCIUM

F. Nurk and R. Niro
Institute of Biochemistry, University of Antioch, Detroit, MI 26405, U.S.A.

INTRODUCTION. Fructose 2,6-bisphosphate (Fru-2,6-P_2) is an allosteric activator of 6-phosphofructo-1-kinase, the rate-limiting enzyme of glycolysis (1) and especially in the hormonal regulation of carbohydrate metabolism in mitochondria (2).

Here we present data on the ability of ascorbate, niacin, biotin and Ca^{++} to enhance mitochondrial Fru-2,6-P_2 levels, suggesting a possible role for protein kinase C and Ca^{++} in the control of this regulatory metabolite.

EXPERIMENTAL PROCEDURES. Preparation of mosquito mitochondria was performed as previously described (3). For the experiments, 0.2 ml portions of mitochondrial suspension in Tris-Hepes buffer (50-100 x 10^{-1} organelles) were shaken at 37° C in a water bath in the presence of 5 mM glucose and the substance to be tested. The samples were assayed for Fru-2,6-P_2 content according to the method of Van Schaftingen et al. (4).

RESULTS AND DISCUSSION. Previously we demonstrated the key regulatory role of Fru-2,6-P_2 in the control of basal and ascorbate-stimulated mitochondrial glycolysis (2). In this study we have examined the effects of niacin and biotin on mitochondrial Fru-2,6-P_2.

The results are shown in Fig. 1 and Table I. All three compounds were able to enhance the metabolite levels with a different time-course. Ascorbate slowly raised Fru-2,6-P_2 to values which remained constant within 2 hours, whereas niacin was responsible for a sustained increase of the metabolite levels with a maximum at 30 min and a subsequent progressive decrease, biotin showed a similar behaviour with a maximum at 15 min.

Fig. 1. Levels of Fru-2,6-P_2 in mitochondria incubated in 5mM glucose alone or plus ascorbate (10 mg/ml), niacin (250 ng/ml) or biotin (20µg/ml). Means of 3 expts.

Ascorbate is responsible for a permanent activation of protein kinase C whereas niacin and biotin induce a transient activation of this enzyme, regarded as one of the important cellular signal transducers (5). The observed permanent enhancement of the Fru-2,6-P_2 elicited by ascorbate and the transient rises induced by niacin and biotin closely reflect the respective patterns of protein kinase C activation, suggesting the possible involvement of this enzyme in the control of Fru-2,6-P_2.

The mitochondrial response is at least in part due to Ca^{++} mobilization, therefore the effect of the divalent cation on Fru-2,6-P_2 levels has been investigated using a low concentration of the ionophore 86360 (Table I). Ca^{++} appears to enhance Fru-2,6-P_2 concentration and interestingly, its action is additive to that exerted by niacin and biotin.

Table I. Effect of ionophore 86360 on mitochondrial Fru-2,6-P_2 levels

	Fru-2,6-P_2 (pmol/mg protein)	
Addition	—	+ 0.1µM 86360, 1 mM Ca^{++}
none	6.0 ± 0.3	12.8 ± 0.3
niacin 250 ng/ml	10.9 ± 0.2	18.8 ± 0.6
biotin 20 µg/ml	11.6 ± 0.4	21.0 ± 0.4

Mitochondria were incubated for 15 min in the presence or absence of the above mentioned substances.

Data reported are the means of experiments performed in triplicate.

From the present study it emerges that Fru-2,6-P_2 metabolism is under the control of protein kinase C and of molecular events linked to Ca^{++} mobilization which likely exert their action by regulating the enzyme responsible for the synthesis of the bisphosphate.

ROYAL SOCIETY DISCUSSION MEETINGS

November and December 1989

8 and 9 November: 'Allochthonous terranes', organized by Professor J.F. Dewey, F.R.S., Professor I.G. Gass, F.R.S., Dr G.B. Curry, Dr N.B.W. Harris and Dr A.M.C. Sengör
Speakers: J.F. Dewey, F.R.S., D.L. Jones, E. Irving, F.R.S., W.B. Hamilton, M.S. Steckler, P.F. Hoffman, N.B.W. Harris, W.G. Ernst, M. Audley-Charles, Jin-lu Lin, A.M.C. Sengör, B.J. Bluck, Y. Yilmaz and I. Metcalfe.

6 and 7 December: 'Migrant Pests: problems, potentialities and progress', organized by Dr R.C. Rainey, F.R.S. and Dr K.A. Browning, F.R.S.
Speakers: R. Skaf, R.A. Cheke, P.O. Odiyo, Mohamed Saddak Boulahya, R.J.V. Joyce, R.B.B. Dickison, W. Wolf, D.E. Pedgley, J.R. Riley, K. Kitenda, C. Zick, J.R. Milford, J.U. Hielkema, R. Le Berre and R.H.A. Baker.

Registration details (no fee for attendance): Miss C.A. Johnson (ref. DMN/CAJ), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG. (Tel: 01-839 5561, ext. 278. Telex: 917876). (1774)M

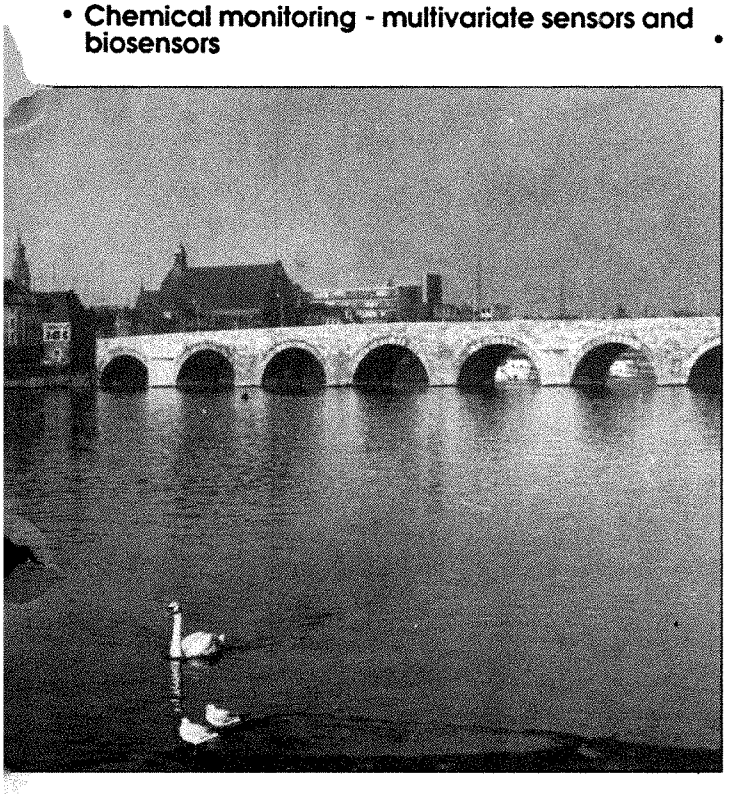
SCIENTIFIC COMPUTING AND AUTOMATION (EUROPE)

nature

Conference and Exhibition, 12–15 June 1990, Maastricht, The Netherlands

ELSEVIER



The 2nd **SCA** conference and exhibition will be held in Maastricht, The Netherlands, an ideal location which takes the meeting into the heart of Europe.

As before, **SCA** is entirely devoted to computing and automation subjects which cross all scientific disciplines; hence the continued theme 'Les Sciences sans Frontières'.

Under the Chairmanship of Dr. Erkii Karjalainen from Helsinki, **SCA** will bring together specialists from a wide range of disciplines with expert knowledge encompassing the following topics:

- **Chemical applications for supercomputers**
- **Sampling strategies and experimental design**
- **Scientific Databases**
- **New Emerging Standards**
- **Dynamic models for catalysis, processes and metabolism**
- **Expert systems and statistical tools for the interpretation of laboratory data**
- **Robotic and discrete automation in the laboratory**
- **Interfacing tools; software and hardware tools**
- **Chemical monitoring - multivariate sensors and biosensors**
- **LIMS and LAN strategies for the laboratory**
- **Workstations for scientists - RISC, parallel and traditional**
- **Scientific applications for neural networks and fractals**
- **Software toolkits for exploratory data analysis and mathematics**
- **Computer graphics and image analysis**
- **Designing molecules by computer**
- **Europe 1992: Implications for standards across borders**
- **Validation and Certification**

(W6555)A

INTERNATIONAL EXHIBITION: An international exhibition will complement the SCA conference - both of which will be held under one roof. The exhibition will be organised by the publishers of *Nature* magazine.

USB's DNA Sequencing

SEQUENASE®

THE ACCEPTED STANDARD AND A 50% DISCOUNT*

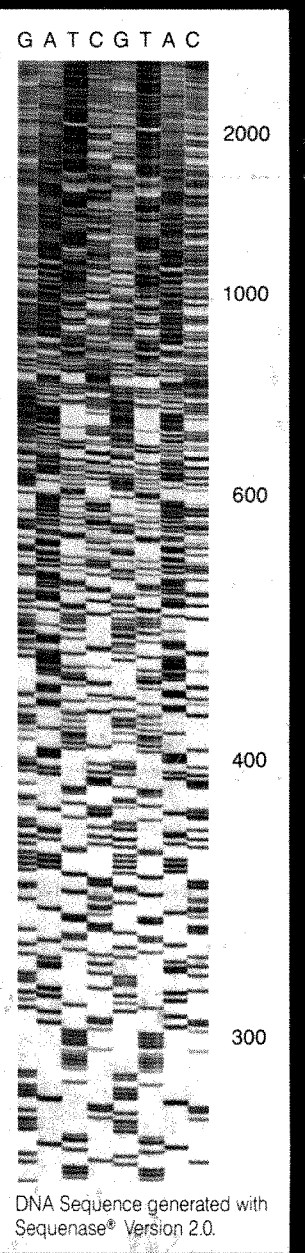
- Proven reliability
- Reduces gel background
- Eliminates compressions
- Gives uniform band intensities
- Resolves 500, 600 or more bases
- Easy to use

Now you can extend the limits of sequencing with the proven Sequenase®**—while saving on your other biochemical needs.

*Purchase the Sequenase® Version 2.0 or Version 1.0 T7 DNA Polymerase kit or enzyme or related Sequenase® sequencing products and USB will give you—absolutely free—anything else you order at the same time (excluding Sequenase® Version 2.0 and Version 1.0 kit or enzyme): up to 50% of the dollar value of your Sequenase® purchase from October 1–November 15.

The Sequenase® Version 2.0 and Version 1.0 DNA sequencing kits are based on novel forms of T7 DNA polymerase specifically engineered for DNA sequencing. Both Sequenase® Version 2.0 and Version 1.0 kits contain all reagents necessary to run at least 100 sequences using dGTP or dITP. The Sequenase® Version 2.0 kit has, in addition, dGTP and dITP sequence extending mixes. This Version 2.0 kit now also includes Mn Buffer.*** Mn Buffer is used for more reliable sequencing close to the primer even when using sub-optimal quantities of template.

Check our catalogs and make your selection, being sure to specify in what combination, to take full advantage of USB's standards of excellence—and our unsurpassed reputaton for purity, quality and service. Then get it free; up to 50% of whatever you spend on Sequenase® in the same order.



For a free copy of our Molecular Biology or General Biochemical catalogs, write USB at P.O. Box 22400, Cleveland, OH 44122. U.S. and Canada phone 800/321-9322, Ohio call collect 216/765-5000. Telex: 980718. Fax.: 216/464-5075.

**Sequenase T7 DNA Polymerase U.S. Patent 4,795,699. Patents pending in U.S. and other countries.

***Patent pending.

TRIGGERING OF VOLCANIC ERUPTIONS

METTLER PM with Application Pacs

Consider it a species that adapts to your natural habitat.

One usually doesn't start out in life prepared for everything the future may hold. But for a METTLER PM precision balance that's a normal state of being.

The capacity to change and evolve into a higher order is built into the METTLER PM from inception. So no matter what you need a balance to do to keep up with your changing needs, you won't be disappointed.

Besides inheriting METTLER's tradition for quality, the PM offers a long line of options, Pacs and peripherals that make it everything you ever wanted your balance to be.

In fact, the METTLER PM balance is so intrinsically flexible, it could make all other balances an endangered species. Call us for information and make a change for the better.

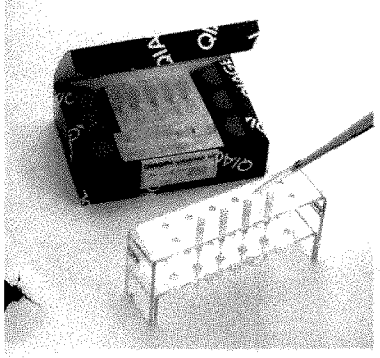
Hi purity lambda DNA

QIAGEN *Hi purity* >lambda< kits will dramatically change the way you isolate lambda DNA. The QIAGEN >lambda< kit series represents a complete purification system. Lambda kits are available for either Mini, Midi, or Maxi preps of lambda DNA, containing all buffers, reagents, protocols and the QIAGEN mini columns.

QIAGEN means:

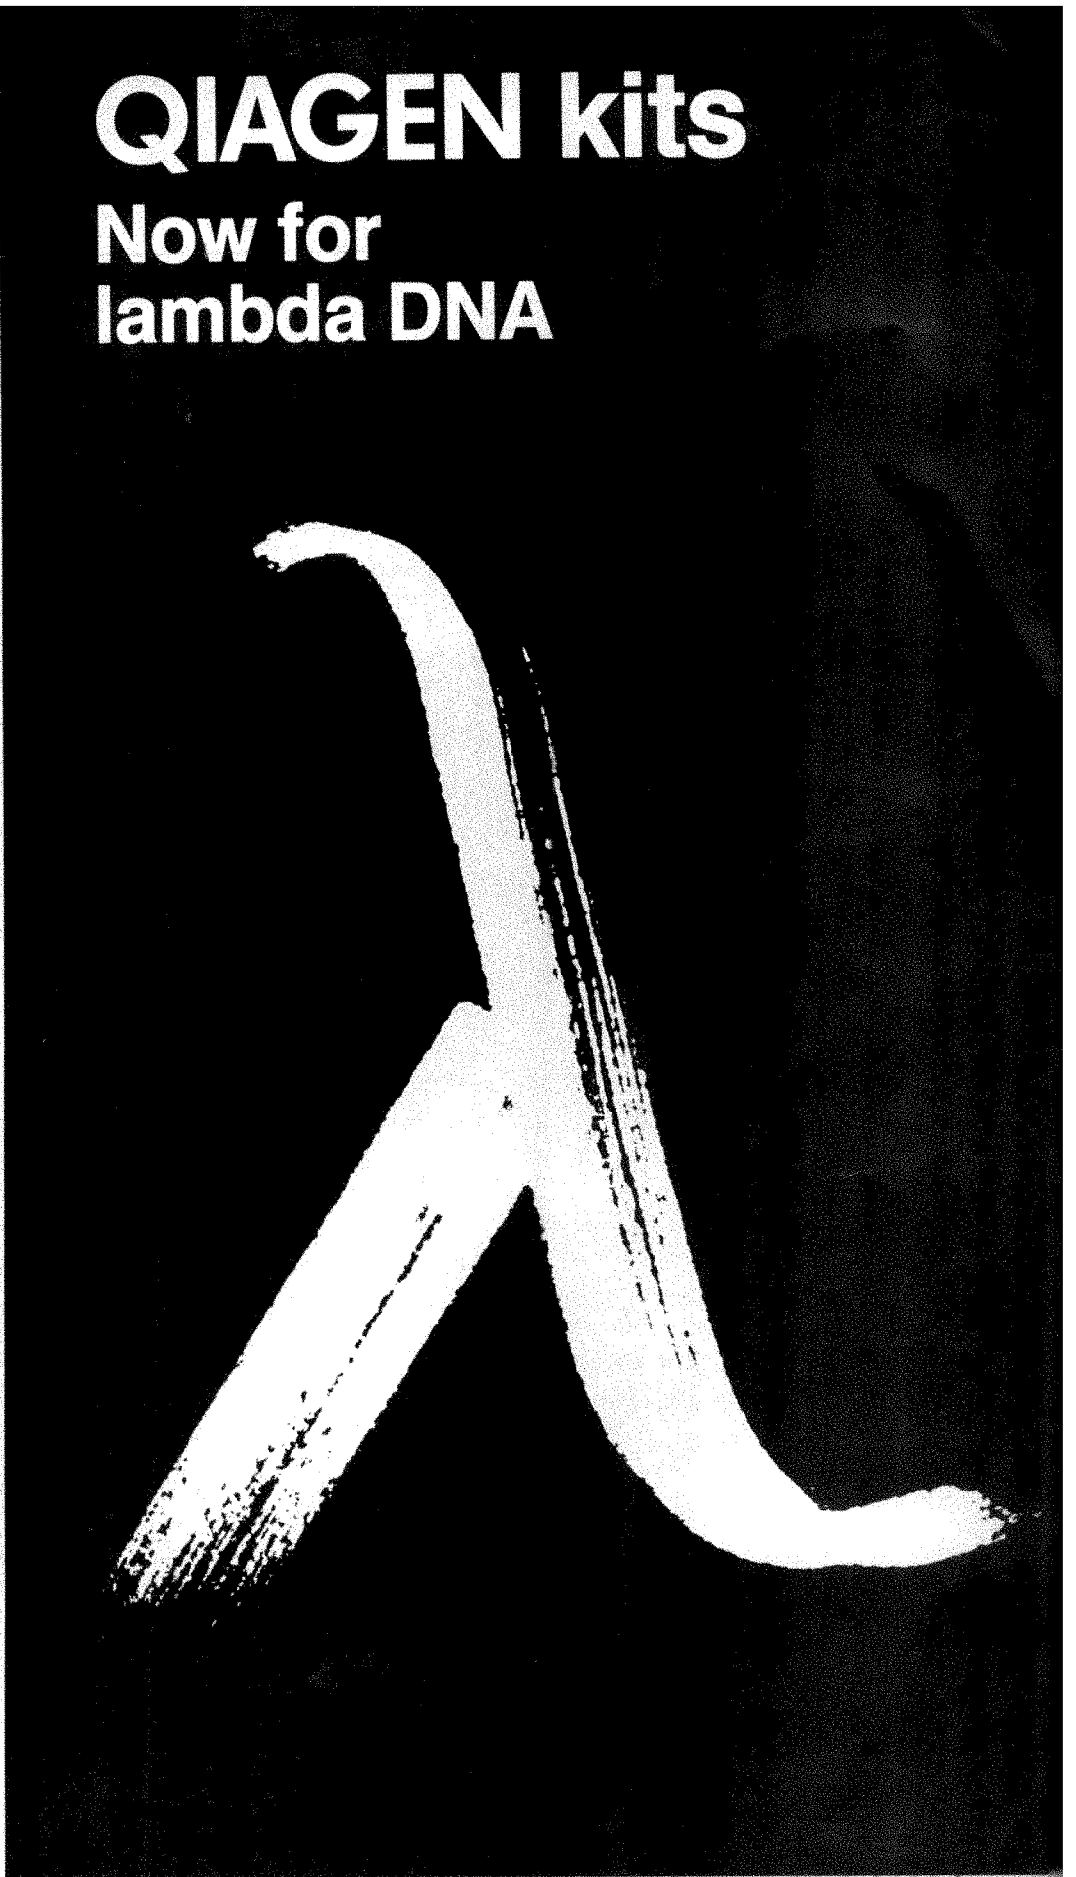
High Purity DNA
Speed and Convenience
No Phenol
No CsCl or Ultracentrifugation

With QIAGEN CsCl purity is equalled:



Pure lambda DNA can be isolated rapidly and economically using QIAGEN kits and easy-to-follow protocols. It is ideally suited for:

Cloning
Enzymatic processing
Sequencing



QIAGEN mini columns

contain our unique-anion-exchange resin QIAGEN that guarantees the selective isolation of different classes of nucleic acids, and the complete removal of proteins, polysaccharides and metabolites.

QIAGEN kits are now available for plasmid DNA and lambda DNA

CRYSTAL

SAPPHIRE

all image processors are not the same

and noise reduction is only part of the story

Most systems available today begin with noise reduction – and that's where the image processing ends.

Now Sapphire takes over, with analogue gamma correction to optimise the input signal: with unique **Real-time** digital shading correction and with histogram equalisation facilities, compensating for uneven illumination or high profile subjects. **And** it has the most rapid and sophisticated noise reduction in the business.

It's not simply a pursuit of clever processing which defines Sapphire, but cool headed economic performance. The new shading-correction capability alone significantly extends the useful life of camera and intensifier by compensating for wear.

Just one of the ways that Sapphire pays for itself, time and again.

Sapphire deserves a closer look – call us now for the full picture or use the reply number for rapid response.

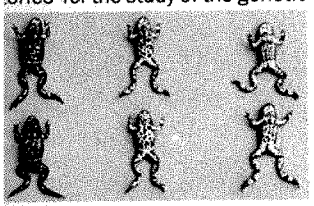
Vol. 341 Issue no. 6242

◀ Hydrogen-isotope studies of lava samples from the growing lava dome of the active volcano Mount St Helens in Washington State have been used to deduce information about the process of magma evolution and extrusion (page 521). The cover shows the crater and lava dome in December 1980 (US Geological Survey).



THIS WEEK

DNA linkage

A link between cell-cycle control mechanisms and DNA replication is provided by the demonstration that cdc2 protein kinase can phosphorylate SV40 T antigen, and thus activate binding of this protein to the viral origin of replication. Article, page 503.

Neighbours

Hybrid zones, the narrow regions in which genetically distinct populations meet, mate and produce hybrids, provide 'natural laboratories' for the study of the genetic

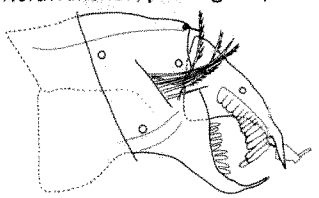
Pure Bb hybrids and pure Bv toads.

differences responsible for speciation and the spread of alternative adaptions. Review page 497.

Plotting the Phanerozoic

Direct dating of carbonates in sediments formed during the Phanerozoic (from ~590 million years ago) has proved problematic. But on page 518, the successful use of the uranium-238/lead-206 method is reported, suggesting that this could be a valuable tool for refining the Phanerozoic timescale.

Patchy response



Patched is the only *Drosophila* gene known to be required for development of pattern elements from the middle of each segment. The sequence of the gene predicts that its product is a novel kind of membrane protein, consistent with the presumed role of *Patched* in cell–cell interactions that elaborate pattern within segments during embryo-genesis, page 508.

Alternative to mAbs

Immunoglobulin V_H gene segments cloned directly from immunized mouse spleen can bind specifically to antigen in the absence of antibody light-chain. 'Single-domain antibodies' produced by this method give some of the useful properties of monoclonals, but are more simply produced. Pages 544 and 484.

Going back in time

Fossilized pseudoscorpions, primitive arthropods related to spiders, have been discovered in Middle Devonian sediments in North America, pushing the prob-

able age of the group back from 35 million years to 380 million. This provides further evidence that fully terrestrial arthropods co-existed with primitive vascular plants at that time, page 527.

Local showers

The presence of 'young' Earth-like valleys on Mars conflicts with the belief that the martian valleys were formed when the planet had a primordial atmosphere with an Earth-like hydrological cycle. Local effects can provide the 'missing' ingredients, page 514.

Opening bat

Two groups of neurons have been identified in the midbrain of the horseshoe bat, with properties suggesting involvement in the process by which the bat compensates for flight-induced Doppler shifts in the frequency of its echolocation call. Pages 529 and 488.

GENECLEAN®

PURIFY DNA FROM AGAROSE IN 20 MINUTES

- **REMOVE AND PURIFY DNA FROM AGAROSE GELS FAST** ... 20 minutes from Gel-Band to purified DNA in water or TE.
- **REMOVE EXCESS LINKERS, PCR PRIMERS, UNREACTED LABELLED NUCLEOTIDES and/or DESALT AND CONCENTRATE DNA SOLUTIONS, EVEN THOSE IN PHOSPHATE, FAST** ... 15 minutes without columns, alcohol precipitations or organic extractions.
- **ELIMINATE ENZYME-INHIBITING IMPURITIES FROM DNA SOLUTIONS FAST** ... 15 minutes to remove protein, small RNA and other enzyme-inhibiting impurities from DNA solutions. For example, remove RNA and protein from crude mini-plasmid cleared-lysates without protease, RNase, organic extractions or alcohol precipitations.
- **ELIMINATE NEED FOR ALCOHOL PRECIPITATION OF DNA** ... 15 minute **GENECLEAN** process serves the same purpose as alcohol precipitation of DNA, often with increased recovery.
- **REMOVE TRACES OF ORGANIC SOLVENTS FAST** ... 15 minutes to remove residual enzyme-inhibiting phenol, chloroform or ether from extracted solutions of DNA.
- **"QUICKCLONE" FROM HIGH MELTING-POINT AGAROSE GELS.**

DNA TREATED WITH GENECLEAN® IS free of RNA, proteins and other contaminants that inhibit enzymes and is a ready substrate for restriction enzymes, polymerases, ligases and kinases. Single and double stranded sequencing reactions are remarkably free of ghost bands caused by self-priming activity of RNA. The highly pure DNA transforms procaryotic or eucaryotic cells with high efficiency.

THE GENECLEAN® KIT provides excellent recovery of single and double stranded DNA and it is not inhibited by SDS, organic solvents or protein.

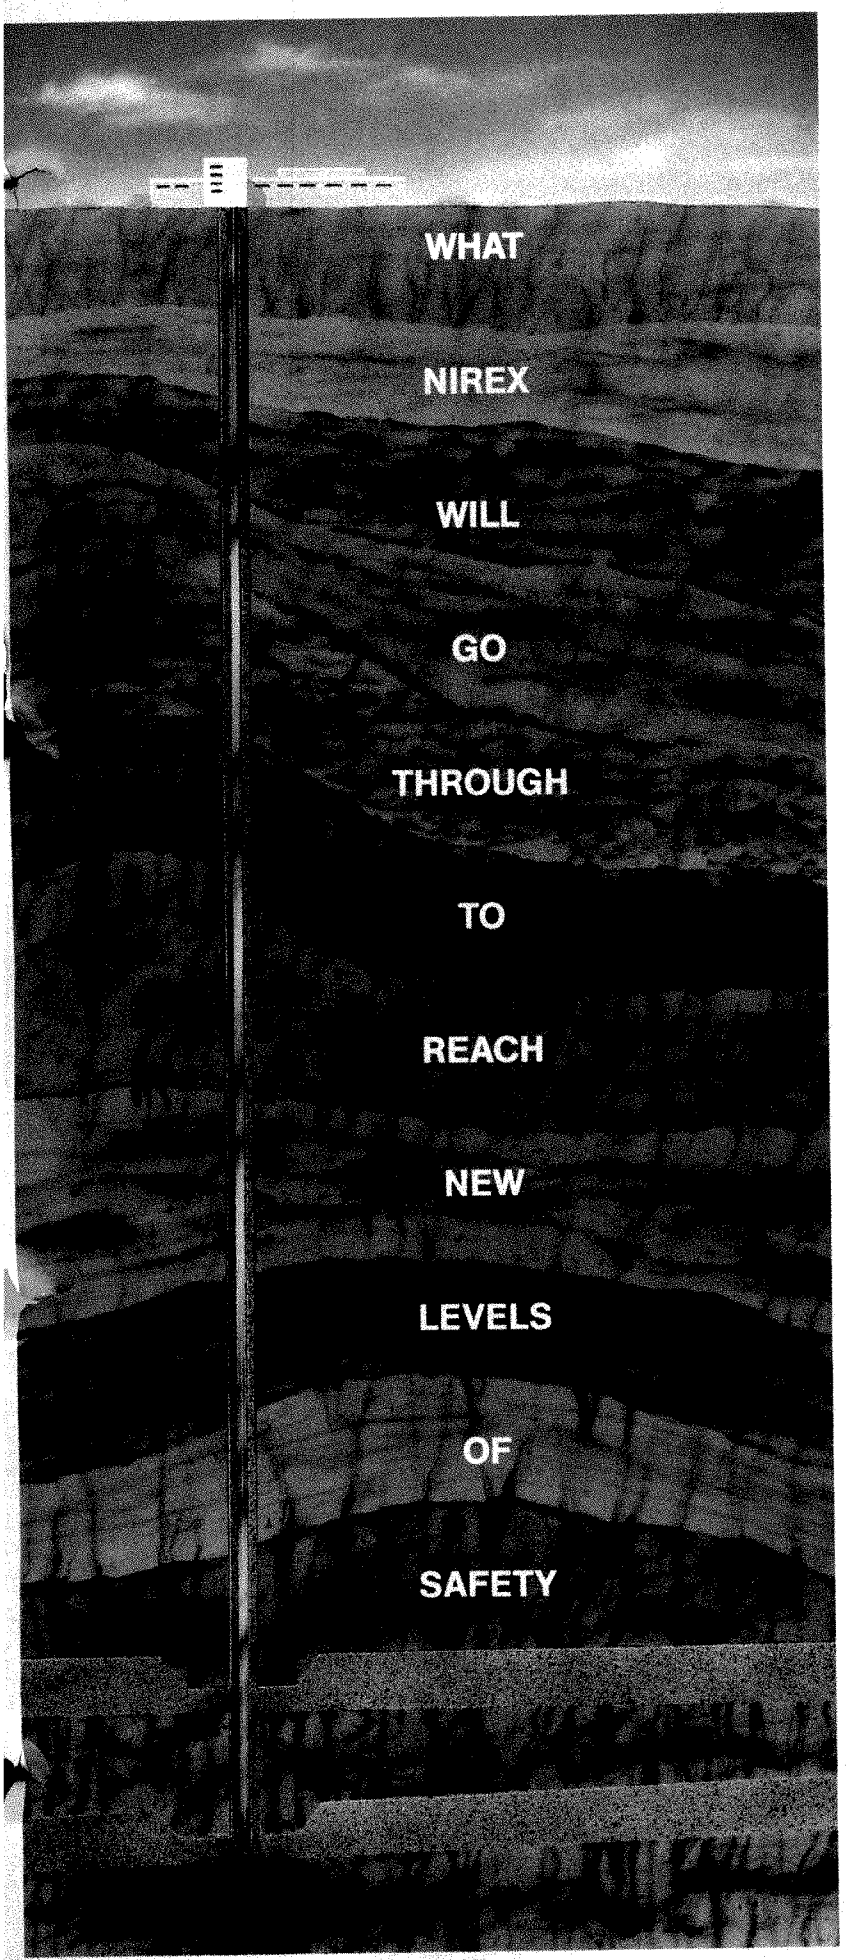
When the Talk Turns to cDNA Library Construction, Turn to the Leader...

...the Librarian from Invitrogen.

The Librarian family of cDNA library construction systems are versatile, easy to use, and are the only systems that contain all of the materials needed to take you from mRNA to recombinants.

The Librarians offer:

- Modular design that includes prepared vector, E. coli and all enzymes and reagents; quality controlled as a complete system for optimum efficiency;
- Your choice of mammalian, yeast, or prokaryotic expression vectors which simplify isolation, characterization and expression of cloned sequences;
- The convenience of functional screening, sequencing, mutagenesis and subtraction directly from libraries constructed in the Librarians phagemid vectors;
- A highly efficient method for size selecting cDNA generated by random or oligo dT priming;
- Technical service personnel with the experience to provide reliable information and assistance.



If you're talking about cDNA library construction and haven't talked to Invitrogen, it's time to pick up the phone.

Reader Service No.700

Five hundred metres of solid rock to start with. But that's only part of the story.

Before we put forward proposals to build a deep underground repository for Britain's low and intermediate-level radioactive waste, we must thoroughly understand not only the science and engineering of the waste and the repository itself, but also the geology of the possible sites.

To achieve this we have commissioned millions of pounds worth of research from universities, laboratories and companies, and have started a major geological investigation programme. When we finally make proposals to build a repository we must be confident they will satisfy safety standards that are amongst the toughest in the world.

This project, comparable in engineering terms to the Channel Tunnel, will cost at least £1.6 billion and will serve the country's needs for 50 years.

For further information write to The Information Officer, UK Nirex Ltd., Curie Avenue, Harwell, Didcot, Oxfordshire, OX11 0RH, or telephone Peter Curd on 0235 833009.

Quantikine™

For the Precise Quantitation of Cytokines.

ELISA Kits for TNF-*a*, IL-1β*, IL-4*, IL-6

R&D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive: linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.

Precise: well-to-well CV <8%

Specific: results not influenced by the presence of other cytokines.

Accurate: eliminates the inherent imprecision of bioassays.

Rapid: simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample...Incubate (2 hours)...
Wash...Add Detection Antibody...
Incubate (2 hours)...Wash...
Develop...Read Results.

ECET Femtotip®

The tip-top standard capillary

Our tip for microinjection

The ECET Femtotip has the top form for microinjection. The design and outlet diameter (0.5 ± 0.2 µm) of this standard capillary are optimized for accurate microinjection in tissue culture cells. You can start microinjection at any time. The hazard of blockages is reduced to a minimum with Eppendorf's precisely designed Femtotips.

Simplified operation

With the aid of the Eppendorf Microloader, all capillaries can be filled with filament. The Microloader is a very finely pulled pipette tip that fits Eppendorf Pipettes 4700 and 4710. It places the liquid to be injected near to the capillary tip. By keeping the path of the injection liquid to the capillary tip as short as possible, you minimize adsorption, aggregation and concentration effects. Therefore, you can even handle smallest volumes with outstanding precision.

FAST TRACK,* ™

The Highest Quality mRNA from Cells or Tissue in 4 Hours Flat...

Get The Message

The FAST TRACK mRNA isolation kit will efficiently isolate high yields of intact poly A^+ RNA directly from cells or tissue in less than four hours!

/// Double the Yields of Standard Procedures

/// Combines Speed and Simplicity with Higher Yields of Intact RNA

/// Half the Cost of Other Antiquated Procedures

/// Isolation of mRNA from Small or Large Tissue Samples

/// A Complete Set of Pretested Reagents and a Simple-To-Follow Instruction Manual

The FAST TRACK™ procedure gives you consistently higher yields of active, intact mRNA for the construction of cDNA libraries, primer extension, RNase A protection analysis and Northern blots. FAST TRACK yields 40-100µg of poly A^+ from 10^8 cells or 1 gm of tissue.

Let Invitrogen put you on the FAST TRACK. To order, ask for catalog No. K1593-02 after calling ...

*patent pending

Thanks for your help!

We asked you, the user of oligonucleotide synthesizers, the producer of oligonucleotides, how we could improve oligonucleotide synthesis for you. The result was Gene Assembler® Plus, our new oligonucleotide synthesizer.

As Easy as A, C, G, T...

- **Truly easy software,** making handling, synthesis and maintainace really simple.
- **Preprogrammed optimised synthesis methods,** including custom synthesis and a program for 5'-aminoalkylation.
- **Unique monitoring system,** reporting the success of synthesis with automatic feedback control to interrupt the synthesis if something should go wrong.
- **Automatic documentation,** of sequences and results.
- **PAC amidites for better results.** PAC amidites give a purer product due to less depurination.
- **Faster results,** deprotection with PAC amidites and support takes only 60 minutes.

The concept of Gene Assembler Plus is to make oligonucleotide synthesis easier, to improve performance and results. Thus making it perfect for all oligonucleotide synthesis including PCR primers.

The positive reaction Gene Assembler Plus has received testifies to the contribution you've made.

Why not contact us today and find out more about what Gene Assembler Plus can do for you!

We help you manage biomolecules.

Repligen IPA-300: The Protein A that can cut development time

Repligen provides ultrapure and immobilized rProtein A with complete documentation on file with the FDA and full support from our experienced staff of regulatory affairs specialists. This means that you lose less time substantiating your materials and complete your IND submission faster. Plus IPA-300 guarantees high binding and virtually no leakage to the toughest specifications in the industry. So for the consistent purity you need for single pass purification of therapeutic grade monoclonal antibodies, specify Repligen's IPA-300. Whether it's 2 milliliters or 2 liters, we'll ship in one business day. Cut through the paperwork. Call us today.*

A high performance radiation monitor designed with your pocket in mind.

The RadAlert 1201 is a compact radiation monitor with a truly high performance, but a modestly low price – just £169 + VAT (US$299).

Its built in microprocessor gives accurate measurements of both Gamma radiation and X-rays on a clear digital display. RadAlert comes with three operational modes – instant dose rate, extended dose rate (with your accumulated dose since you turned RadAlert on), and counter.

You will find it invaluable wherever you need to monitor anything from normal "background" radiation to 10 millisieverts/h. It will automatically select between micro and milli sieverts, and you can choose integrate periods of 4 seconds or one, two, five or fifteen minutes.

It's energy compensated over the range 50 KeV to 1.25 MeV.

RadAlert is fully portable (a rechargeable battery is fitted as standard) but it can also be used in a fixed location with our optional AC/DC adaptor.

You can program its audio-visual alarm to trigger at any level across the full range of the instrument. And there's a distinct warning should RadAlert's capacity be exceeded.

For bulk orders, we can customise the software to meet your operational requirements. We could, for instance, re-program the microprocessor to display only the accumulating dose, and feature your company's name. Please contact us for further information.

RadAlert has been fully tested by the National Radiological Protection Board. It comes with three educational booklets and a full 2-year warranty.

Order your RadAlert now by calling us on (44) 1 486 6837, faxing us on (44) 1 487 3023, or returning the coupon. Or contact us on the same phone numbers for more details. Dealer enquiries are welcome.

RAD ALERT

The World's Most Effective Separation Tool

It's the Beckman TL-100 tabletop ultracentrifuge for rapid, efficient runs.

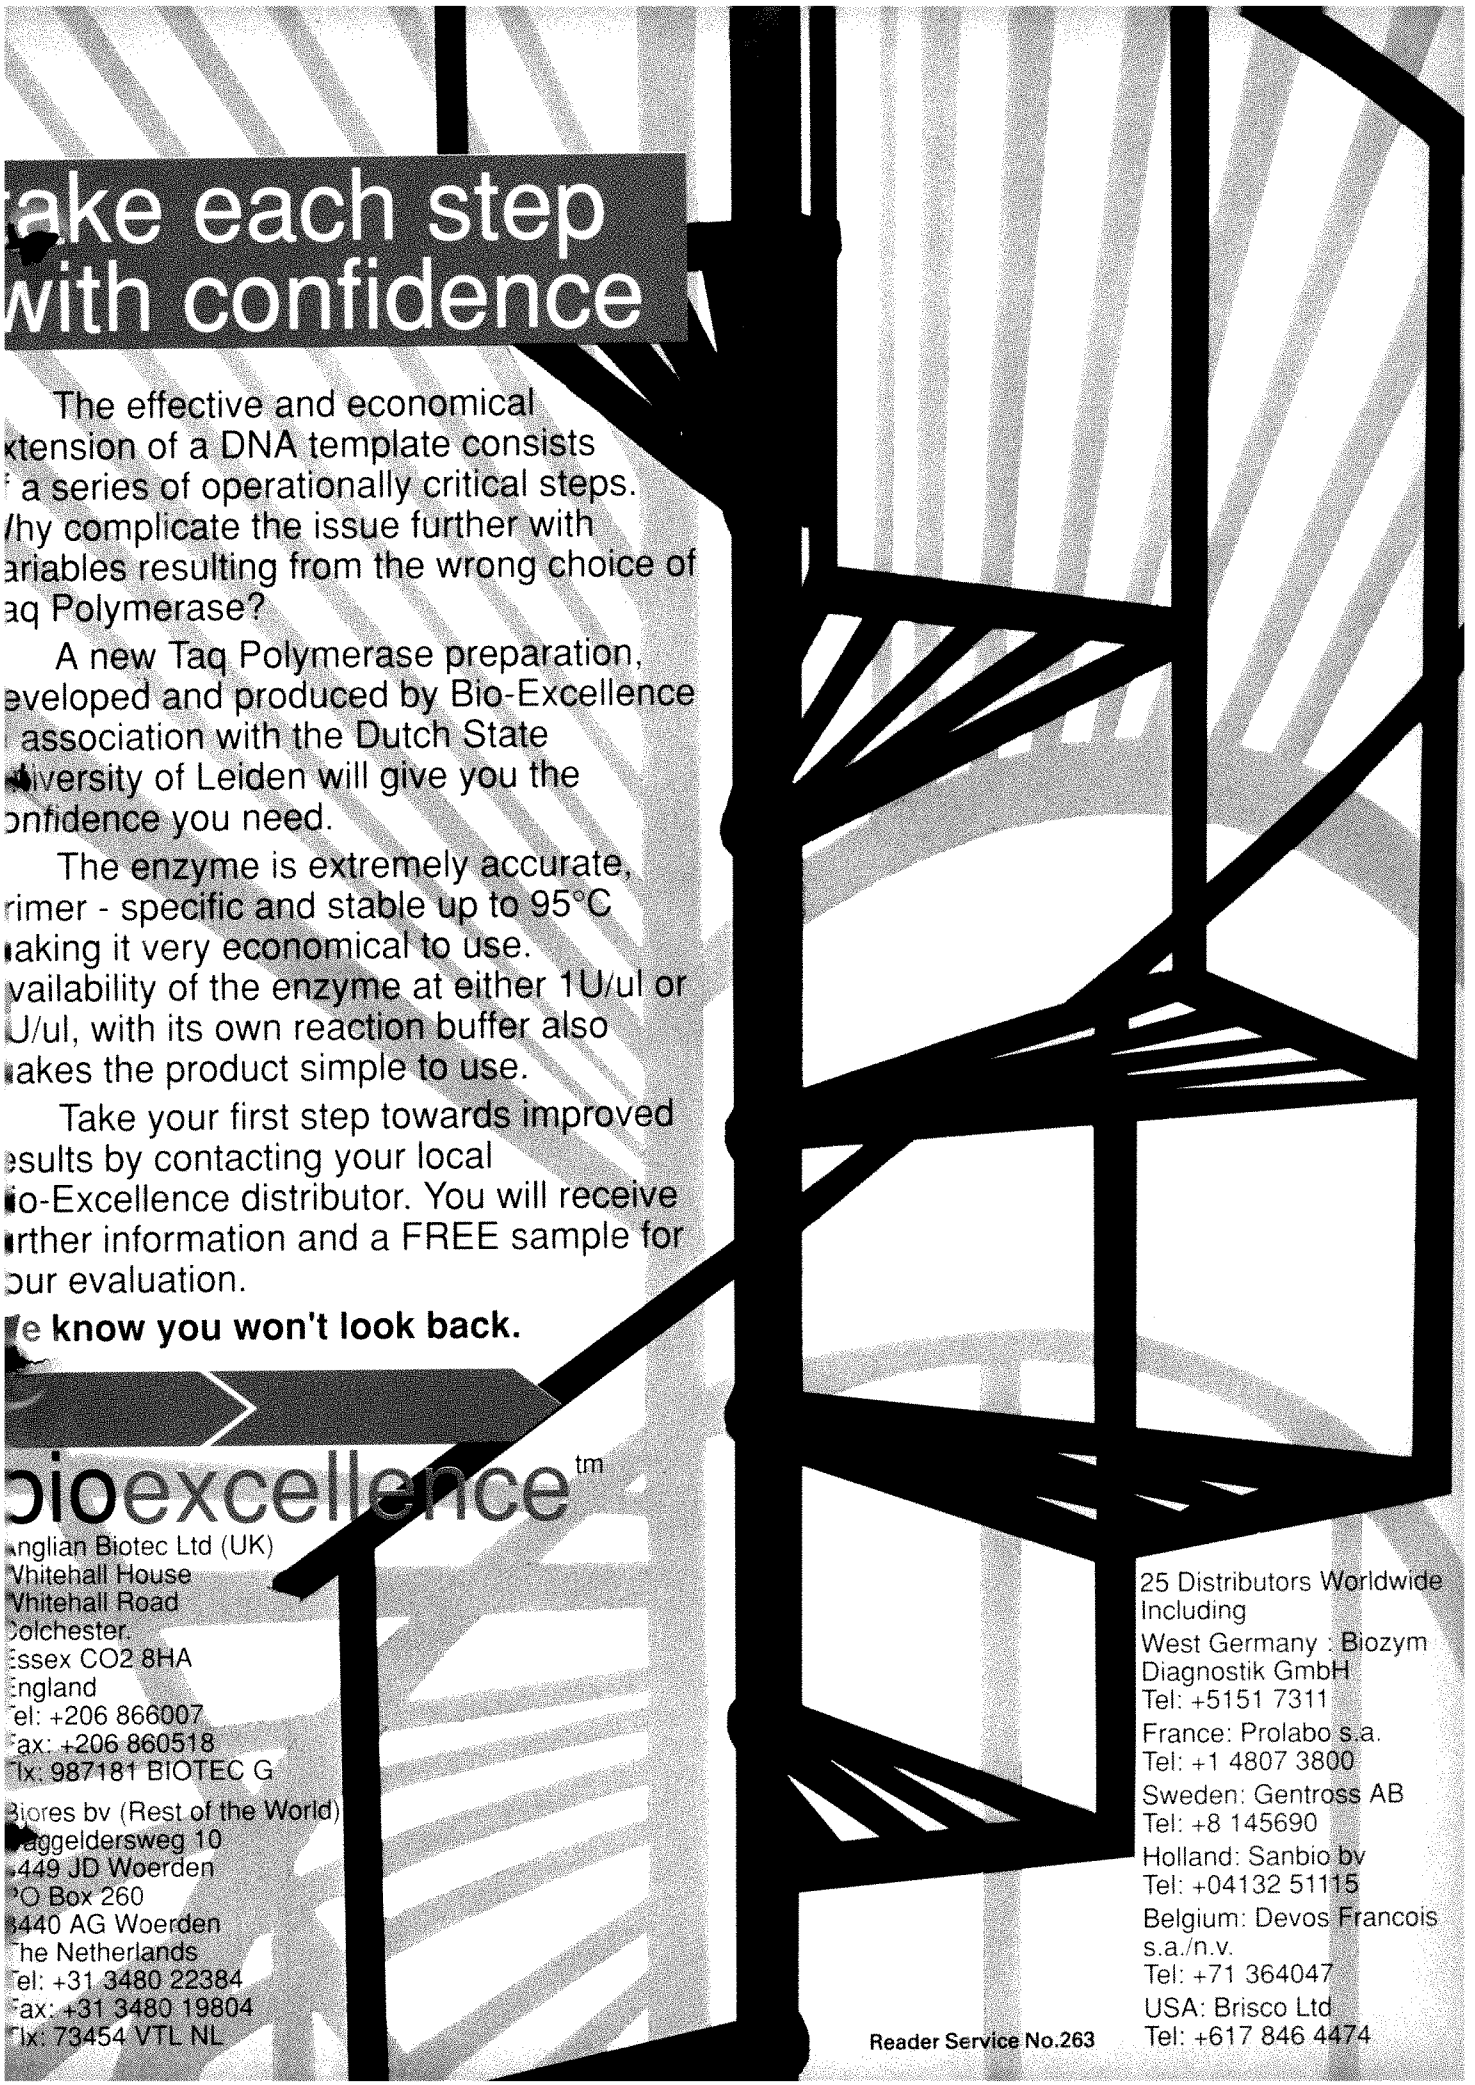
The proof is in the applications literature:

- **Isolate both DNA and RNA in one 3-hour CsCl gradient run in the TLS-55 rotor.**
  P. L. Iversen et al., BioTechniques 5, 521, 523-524 (1987)
- **Prepare rabbit reticulocyte fractions with four times the protein synthesis activity of conventional preparations in 20 minutes using the TLA-100.2.**
  J. W. B. Hershey, Application Note DS-711. Beckman Instruments, Spinco Division, 1987.
- **Isolate DNA in 4-5 hours on CsCl-ethidium bromide gradients run in the TLA-100.2 rotor.**
  D. P. Weeks et al., Anal. Biochem. 152, 376-385 (1986)
- **Pellet RNA through a CsCl cushion in 2.5 hours using the TLS-55 rotor.**
  M. G. Peterson and J. F. B. Mercer, Eur. J. Biochem. 160, 579-585 (1986)
- **Separate lipoprotein fractions by a single 25-minute spin in the TLV-100 rotor.**
  J. P. Segrest et al., Beckman TL-100 News 1:2, 1-2 (Dec. 1986)
- **Prepare a protein-free plasma fraction for drug binding studies by a 1-hour run in the TLA-100.2 rotor.**
  T. Zysset, Ther. Drug Monit. 9, 433-438 (1987)
- **Clarify solubilized membrane proteins in 15 minutes in the TLA-100.2 rotor.**
  P. H. Lin et al., Biochemistry 26, 731-736 (1987)
- **Separate lipoprotein fractions using single or serial 2.5-hour runs in the TLA-100.2 rotor.**
  H. K. Naito, Applications Note DS-693. Beckman Instruments, Inc., Spinco Division, 1986.
- **Estimate sedimentation coefficient of a protein from a 4-hour sucrose gradient run using the TLS-55 rotor.**
  D. L. Gard and M. W. Kirschner, J. Cell Biol. 105, 2203-2215 (1987)

Small wonder the TL-100 has become the fastest selling ultracentrifuge in the world!

For more information, including our new annotated applications bibliography with over 100 literature references, contact Beckman Instruments, Inc., Spinco Division, 1050 Page Mill Road, Palo Alto, CA 94304. (800) 742-2345. Offices worldwide.

BECKMAN



NEW

TLA-45 fixed angle rotor holds 12 1.5-mL conical-tip tubes at a 45° angle and spins them at 45,000 rpm/125,000 *g*. Refrigerated microcentrifuge capability for the TL-100!

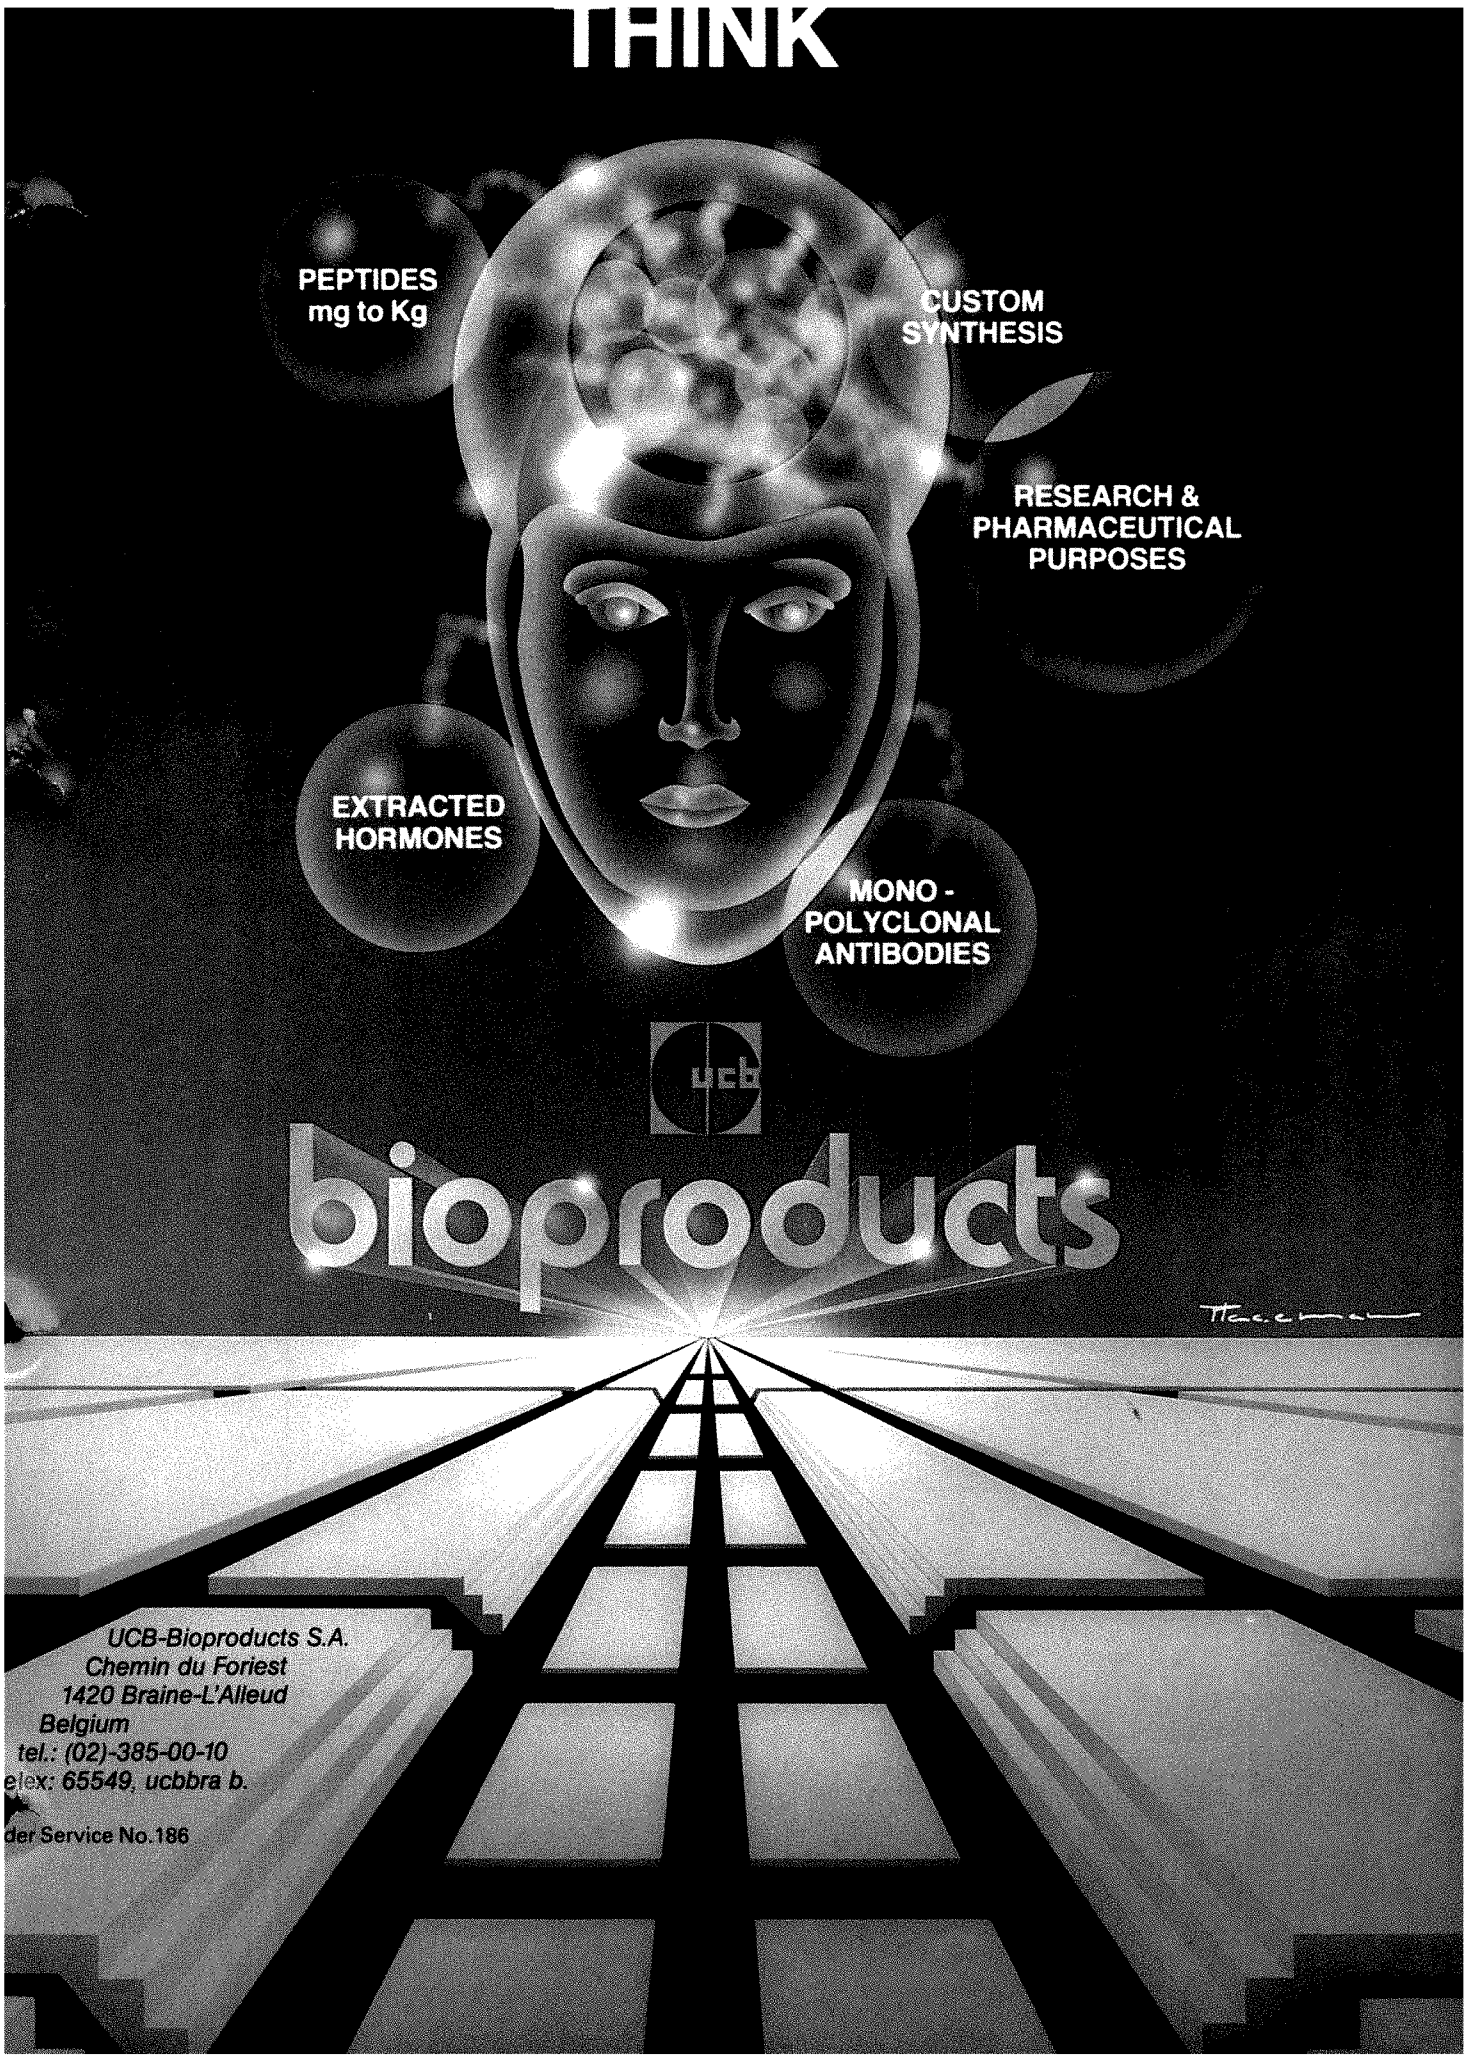
THINK BIG

Asahi Chemical is far larger and more diversified than most people realize or might even imagine, as one of the world's foremost suppliers of technologies and products for industrial progress.



Products from Asahi Chemical range from fibers, petrochemicals, and plastics to food, housing, and microelectronics, and are an integral part of industry, society, and everyday life.
Sixty years of research and development for advanced technology has brought a comprehensive range, and a tradition of exploration and discovery.
This pioneer spirit challenges the frontier of knowledge and possibility, and is now at work in biotechnology, optoelectronics, advanced energy processes, and new high performance materials.
As a leading corporation with comprehensive, integrated operations in development, manufacturing, and sales, Asahi Chemical will continue to identify and meet the needs of modern society.

KNAUER
SCIENTIFIC INSTRUMENTS

We will exhibit: Biotechnica, Hanover Oct. 17-19, 1989 Booth G 27

A NEW AGE IN PROTEIN SEQUENCING

The KNAUER Modular Protein Sequencer Model 810 automatically controls complete Edman degradation including isomerization and identification via on-line HPLC.

★ high repetitive yields effected by:
— sequence analysis of the sample on PVDF support in the micro chamber of the new Cross-Flow Reactor
— new miniaturized valves for microdelivery
— full liquid phase delivery
★ optimal sequence analysis of blotted proteins
★ high sensitivity
★ short cycle times (approx. 30 min)
★ very low chemical consumption
★ maximum quality at a reasonable price

Please request our special brochure
We would be happy to send you additional information on our entire line of scientific instruments and products, including:

★ Analytical and preparative HPLC columns
★ HPLC systems, pumps, detectors and injection valves
★ UV/VIS Rapid Scanning Detector
★ Osmometers for chemical and medical use
★ Laboratory chart recorders

No relief from poverty's debt

This year's annual jamboree of the International Monetary Fund and the World Bank in Washington two weeks ago has deservedly earned a bad press. Their neglect of poor countries' debts is their most serious failing.

BOTH the International Monetary Fund (IMF) and the World Bank, like the United Nations Organization, are products of that brief spell towards the end of the Second World War when there was an almost general belief that the creation of enlightened institutions would itself spread enlightenment. Both organizations, created along with the Bretton Woods package that gave the world currency stability of a kind between 1945 and the early 1970s, are banks of a kind — and, like more ordinary banks, they ask a price for the help they give. One, the IMF, exists to help members over temporary difficulties, uncomfortably large gaps between imports and exports, for example. The usual price is that assisted governments must follow economic policies dictated by IMF, which they usually find unpalatable. The other, the World Bank, is more like a merchant bank, designed to invest rich countries' capital in poor countries with the hope that they will become less so; the interest rates it charges are low, but rich as well as poor countries are calculated eventually to benefit from the expansion of world trade.

This year's particular complaint is that the two banks, but especially the IMF, have been exuding complacency when the problems confronting them are horrendous. The problems, of course, are those of the poor countries of the world and their mountains of debt — $300,000 million in round numbers. It seems generally to be agreed, even among the commercial banks that are the poor countries' chief creditors, that much of this debt will never be repaid. Why else would the commercial banks feel bound to write down the value of the poor-country debts they carry on their books? But it is one thing for the commercial banks to admit to themselves and their shareholders that their assets are worth less than they had believed, and quite a different thing for them to forgive a particular country's debt even when it is manifestly incapable of paying the interest on its loans, let alone repaying instalments of the capital. That, the banks say, would be a recipe for getting none of their money back. So the banks and the indebted countries are forced to play a kind of poker game whose objective is a redistribution and overall reduction of indebtedness. An international solution, of a kind that the IMF and the World Bank are designed to devise, would be better.

But have there not already been plans for solving the poor countries' debt problems? As it happens, the present Secretary of the US Treasury, Mr Nicholas Brady, and his immediate predecessor (now US Secretary of State), Mr James Baker, are at least the nominal authors of two successive plans to put the poor countries of the world back on reasonable tracks. The Baker plan was a suggestion that commercial banks should trade some of their outstanding debt for governmental bonds of discounted value or even for equity, perhaps in state or commercial enterprises. The difficulty proved to be that even if commercial banks would settle on such disadvantageous terms, they would then be unwilling to lend the further funds that the poor countries need. The Brady plan acknowledged that difficulty by supposing that the IMF and the World Bank would lubricate the transition from the present state of affairs to a more manageable future by using their funds to back arrangements between commercial banks and poor countries.

It is now apparent that even this plan will not work, not least because the members of the IMF and the World Bank have let their meeting pass without voting the extra capital the two banks would need to carry out the task urged on them by Brady. The reasons may have been procedural, but the outcome is inexcusable. But it seems also now to be plain that the reconstruction of Mexico's foreign indebtness, hailed earlier this year as the first success of the Brady plan, may come unstuck, because the commercial banks that have written down their debts are unwilling to throw good money after bad, as they see it. If that happens, despite Mexico's willingness to follow IMF recipes for economic reform, it will fall to the United States to pull some awkward chestnuts from the fire.

Meanwhile, there is no prospect that piecemeal solutions of individual debtors' problems will put the world to rights. The need is for a wholesale solution. How to achieve that? Hard though it may seem, it is right and proper that countries that have hopelessly mismanaged their affairs should not be relieved of their debt — but the prospect that there might be a global settlement could be a more powerful incentive to reform than the individual hectorings of creditor banks are now. But even among the governments doing their level best, there is a danger that any global settlement will bear most harshly on those that have tried hardest, and which might be judged best able to repay in full, or something like it. But there are ways round that. Western commercial banks are forgivably shy of ending up with equity holdings in distant impoverished places, but would the same be true

of well-intentioned debtor governments for example? That is the sort of stratagem that the IMF should be exploring. If it cannot, there may be no choice but an international conference of debtors and creditors at which they hammer out a settlement in concert. The present mess cannot be allowed to continue. □

Amis and MacGregor

British universities cannot expand a second time without qualitative change.

WHEN the first great expansion of British higher education was set in train by the Robbins Report in 1963, public argument in Britain was quickly polarized around Mr Kingsley Amis's complaint that "more means worse". Mr John MacGregor, the British Secretary of State for Education and Science, has evoked none of that trouble by his casual announcement that his government now hopes that the participation rate in higher education (the percentage of school leavers following degree courses either then or later) will increase to 23 per cent by the end of the century (see *Nature* **341**, 371; 1989). But MacGregor will not be able to forget Amis's complaint for long. Already, the vice-chancellors (otherwise rectors or presidents, according to geography) of British universities have made it plain that there will be a reduction of the quality of higher education if the government does not meet the cost of teaching extra students. That is inescapable, but only half the problem.

The error — some would say the folly — of the then government's response to the Robbins report was its assumption that a twofold expansion could be accomplished without a qualitatitve change in teaching methods. One result was the creation of a new crop of universities in the image of pre-existing universities. Only now have the authorities concluded that many British universities are too small to sustain substantial research programmes — or even to be full universities, teaching philosophy as well as physics. (Some have dropped both.) Both the universities and the British government should be careful to avoid that mistake a second time.

The dilemma for both is worsened by the otherwise welcome prospect that secondary education will in future be less specialized. Students at secondary schools will no longer be expected to win places in specialized courses at universities by virtually demonstrating that they can already do what may afterwards be required of them. But universities have traditionally complained that they cannot take young people through the traditional British specialized degree course in three years if students are a whit less well-prepared than at present. The best solution must surely be that some universities should become four-year universities. The question then is merely whether the government will meet the extra cost. On the face of things, it has no choice.

There are intellectual as well as administrative problems for the universities to tackle. The truth is that the extra 10 per cent of young people McGregor is urging towards higher education will have different needs. Britain's higher education is already notorious for production engineers who do not understand economics, historians who are computer-illiterate and scientists who know only English, and that sometimes imperfectly. What will the British system of higher education, jealous of its independence and traditions, do to accommodate the different needs of its new students? Especially now that 1992 is not far away? □

Benefactor needed

There needs to be an imaginative response to a Soviet offer to create an international centre on Lake Baikal.

NOT so long ago, it was common to hear complaints that the Soviet government was allowing the ruin of one of the world's most remarkable natural monuments, the huge inland sea against the border with Mongolia known as Lake Baikal. It is true, of course, that for a long time bureaucratic impediments exaggerated the natural difficulties of reaching this remote place, so that pollution of the world's largest natural reservoir of fresh water could not be independently monitored and assessed. The good news is that the alarms of the past few decades have been without foundation; Lake Baikal remains more or less in its pristine state. The remarkable news is that the Soviet authorities are deadly serious in their willingness to throw Lake Baikal open to international research (see page 481). Even if the rest of the world does not quickly seize the opportunity, there is already enough collaborative work under way to make a respectable research programme.

But it must be hoped that matters will not rest there. The plans put forward are for a research centre sited on the lake whose programme will be determined by researchers, and not by other interests. The objective is not simply to learn more about Lake Baikal, but to tell whether this distinctive body of water holds the key to other contemporary puzzles, the record of climatic change and the pace of tectonic or even evolutionary change, for example. Practical benefits, especially in the development of monitoring techniques, are an extra.

The difficulty, as always, is the accomplishment of this objective. There will be a need, in the next few years, for something like $20 million in hard currency to establish the infrastructure of a working research centre. It would be preferable if governments were not directly involved, although they are the most obvious sources of funds on such a scale. (Russians, accustomed to print money when they need more of it, do not appreciate the struggles required in the West to raise sums of this kind, but Mr Gorbachev's promised budget reforms may change all that.) Could this be a case where one of the larger foundations will recognize that the time has come to back an imaginative scheme imaginatively? □

Australian innovation covered by US patent

■ 'Gene shears' invented in Colorado in 1986
■ Commercial deal with French may be empty

Sydney

CLAIMS that a genetic-engineering technique, popularly called 'gene shears', may turn out to be one of Australia's most profitable scientific discoveries are turning sour, for the elementary reason that a US company filed for patent rights on the same discovery in 1986. And the dispute over priorities raises serious questions about the true worth of a A$22-million (£11 million) commercial development deal that the Australian Commonwealth Scientific and Industrial Research Organisation (CSIRO) made with a French company, Groupe Limagrain.

The ability of ribozymes to cut RNA molecules at specific sequences was discovered by Thomas Cech, working at the University of Colorado in the early 1980s. He made a broad patent application in 1986, although it may well be two more years before a US patent is issued, and even longer in Europe. Cech's technique was developed further in 1987 by Olke Uhlenbeck, also at the University of Colorado, using 'hammerhead' ribozymes. It is not known whether Uhlenbeck has applied for a patent on his part of the work.

In August last year, Jim Haseloff and Wayne Gerlach from the Plant Industry Division of CSIRO published a paper in *Nature* (**334**, 585–591), describing a refined version of Uhlenbeck's hammerhead ribozyme technique, able to act on a greater range of RNA sequences, and with greater specificity, than had been shown before. And in July this year, to much fanfare, CSIRO announced a joint venture with the French agricultural concern Groupe Limagrain to find commercial applications for the gene-shears technology.

Making no mention of Cech or Uhlenbeck, CSIRO announced that it held worldwide patents to the discovery, and that Australia would benefit from the numerous potential applications of the technology in medicine and plant and animal science. But lawyers for the US Biochemical Corporation (USB), which represents Cech and has sole rights to the technology he developed, responded quickly to the Australian announcements.

USB is so confident of the pre-eminence of its claim that it intends to announce, on 20 October, the formation of a new corporate subdivision dedicated solely to the commercial development of ribozyme technology. Earlier this year, USB announced the first product, RNAzyme-Tet.1.0 Ribozyme, based on the new technology, and senior vice-president Vincent Kazmer says that the product would not have been launched "unless USB was confident of being awarded the patent".

Richard Warburg of Fish and Richardson, lawyers for USB and the University of Colorado, supports Kazmer's assertion, saying that Cech's patent application is broad enough to cover any ribozyme, and that any patent granted to CSIRO would be dominated by Cech's.

It now seems that Jim Peacock, head of the Plant Industry Division at CSIRO, had been advised by the Australian Patent Office (APO) that Cech's and Uhlenbeck's papers constituted 'prior art' as early as April this year, before he made widely reported claims that came out in July. "We don't think they [CSIRO] will get their patent", said Stephen Castle of the APO, which has given Uhlenbeck's paper a 'category X' classification, meaning that it is of the greatest relevance with respect to CSIRO's claim.

Peacock says that he was aware of the Cech patent application and the Uhlenbeck work when CSIRO applied for its patent. But he says he cannot remember the APO analysis, although it is automatic for APO to provide its recommendations when a group applies for an international patent through its national office.

CSIRO is about to publish the first example of gene shears technology used *in vivo*, in the *Proceedings of the National Academy of Sciences of the USA*. Because of the extent of Cech's possible patent protection, it is unlikely, according to Warburg, that even in this area of *in vivo* work CSIRO will be able to practise its technology without a licence. "Cech's application made broad and narrow claims. If CSIRO is entitled to anything it is to a narrow claim, the practice of which will still fall within the broader claims made by Cech". **Tania Ewing**

Paris

Groupe Limagrain's legal adviser said last week that a literature search had been carried out before the agreement with CSIRO was signed, but added that he was in the process of studying the dossier on gene shears. He would not say whether Groupe Limagrain had decided to go ahead with the investment with full knowledge of the US patent. Last Monday, a company official said that the company had "no further information about this patent at the moment". **Peter Coles**

Greenhouse seen from South Pole?

London

A SIGNIFICANT loss of snow and ice near the British Antarctic Survey (BAS) base at Rothera has been recorded, according to a Natural Environment Research Council (NERC) report, but whether the inferred temperature rise is symptomatic of greenhouse warming or the result of a natural climate cycle is uncertain.

The report, primarily designed to assess the need for a new airstrip at Rothera, concludes that the importance of research into global climate change outweighs the damage to the environment that an airstrip would entail.

Since 1982, there has been a dramatic rise of 1°C in the mean summer air temperature during January and February, and Dr Lewis Smith, of the BAS, says that evidence of a warming had been recorded at Rothera since 1950. Although the recent rise may seem small, Smith added, it is significant for the polar regions where the ice-cover is very sensitive to temperature changes. The rapid recession of the ice-

Snow-covered mountains in Antarctica.

cover has occurred more swiftly in the South Orkney Islands.

But greenhouse warming is not the only explanation: the world is experiencing a natural warming cycle which is thought to be at a peak. Smith is concerned the greenhouse effect may exacerbate the cycle or delay the expected downturn in temperature.

Dr John King, an Earth scientist at the BAS, said one has to be "very careful before leaping in" and talking about greenhouse warming. Models predicting the environmental effect of a doubling in carbon dioxide suggest that there would be no detectable change in temperature. However, King said simulations of future climates indicate that the first areas to suffer would be the marginal polar regions where the temperature of sea ice is "closely tied up" with land-ice conditions. ■ A meeting of the signatory nations of the Antarctic Treaty started in Paris this week. Britain will oppose the plan to declare Antarctic an international wilderness reserve while France and Australia will urge that the Antarctic Treaty be replaced with a declaration to protect the Antarctic environment. □

TELECOMMUNICATIONS

Break-up of monopoly?

Tokyo

JAPAN's domestic telecommunications giant, Nippon Telegraph and Telephone (NTT), may be broken up into regional companies if recommendations in an interim report released last week by the Telecommunications Council, an advisory body to the Ministry of Posts and Telecommunications, are followed. But resistance to break-up is strong and it is not clear what path the government will take when the council's final recommendations are issued next March.

With 270,000 employees and an operating income of about $45,000 million, NTT is one of the largest companies in the world. Although it was privatized in 1985, and three competitors entered the market, NTT still controls about 98 per cent of the market, and long-distance domestic telecommunications charges remain high. Japan's international telecommunications charges, in contrast, are tumbling as a result of competition (see below).

Of a number of ways to break up the NTT monopoly, the council favours a split into one long-distance company and 11 regional companies, similar to the break-up of the US monopoly American Telephone and Telegraph (AT&T).

The council argues that the split will promote competition, reduce rates for users, and turn NTT into a more productive entity. But both the powerful Japan Telecommunications Workers Union, to which NTT employees belong, and NTT president Haruo Yamaguchi have come out publicly against the council's recommendations. Yamaguchi says that break-up would increase local rates and create regional differences in charges, and adds that it would interfere with NTT's development of a digital Information Network System (INS) and weaken NTT's research and development capabilities. But opinions in NTT management are said to be divided, with those on the sales and administrative side favouring restructuring while those with an engineering background tend to oppose it.

Proposals to split up NTT when it was privatized in 1985 were shelved because of strong opposition from NTT and some members of the ruling Liberal Democratic Party. Now, however, NTT has lost a lot of political influence because of its involvement in the Recruit scandal which forced the resignation of the then Prime Minister. But NTT still has many powerful friends, including the Federation of Economic Organizations (Keidanren) which opposes break-up.

An important element in the government's thinking will be the effect of break-up on the price of NTT shares. The government has been selling off NTT shares to the public and using the proceeds to help pay off the national debt and finance public works construction. But after rising to a high of about ¥3 million (about $20,000) per share the price has plummeted to ¥1.4 million and the next sale of government-held shares has been postponed.

David Swinbanks

Time to call Japan

Tokyo

A PRICE war may be about to begin in Japan's international telecommunications market, only recently opened up to competition. On 1 October, two new telecommunications companies, International Telecom Japan (ITJ) and International Digital Communications (IDC), began international telephone services with rates 23 to 40 per cent lower than those of the former monopoly Kokusai Denshin Denwa (KDD). But just before the services began, KDD announced new rates, effective from 1 November, that are almost as cheap as those of the new companies. KDD had already reduced its rates considerably in anticipation of competition.

The new companies were at the centre of a trade dispute with the United Kingdom and the United States two years ago, when the Japanese government tried to block participation of Britain's Cable and Wireless and other foreign companies in IDC. One concern of the government has been that establishment of the new companies could result in "excessive competition". Both companies have said they will offer rates considerably cheaper than those of KDD, and a spokesman for IDC says further price reductions are under consideration.

HYDROELECTRICITY

Indian dams go ahead

Bangalore

To the disappointment of Indian environmentalists, the World Bank has not only agreed to provide around 10 per cent of the estimated cost of the gigantic Narmada Sagar-Sardar Sarovar dam project but has also expressed its satisfaction over the plans drawn up to resettle the people evacuated to make room for it. The US Environmental Defense Fund and Environmental Policy Institute had earlier appealed to the World bank to withdraw its support, but the bank has apparently been impressed by the work of Sanat Mehta, chairman of the Sardar-Sarovar Narmada Sagar Nigam, an agency charged with the task of speeding up the project and dealing with the evacuees.

In its present form, the Narmada Sagar and Sardor-Sarovar project together are designed to yield about 2,500 MW of hydroelectric power and will irrigate about 2 million hectares. The entire scheme involves the construction of 30 major dams, and many smaller ones, on the Narmada river and its tributaries. Mehta says that those affected will be given irrigable land, housing plots, agricultural aid, resettlement grants, free transport and civic amenities. This offer is, he says, "unparalleled and unmatched in the world". But a recent study commissioned by the Indian National Trust for Art and Cultural Heritage (INTACH) concludes that the objectives set out by the planners will not be achieved with the present plans. V. Paranjype of INTACH fears that the whole project will come to a halt within two or three years for lack of funds, and that money intended for rehabilitation will go elsewhere.

AIDS TREATMENT

'Parallel track' for ddI

Washington

THE announcement that dideoxyinosine (ddI) will be made available to AIDS patients outside the current clinical trials is a victory for AIDS activists, who have been fighting for early access to drugs working their way through the drug-approval process of the US Federal Drug Administration (FDA). But the victory is tempered by signs that the drug may be more toxic than originally reported.

Results from the recently completed 'Phase 1' safety trials show that ddI, a nucleoside analogue that blocks HIV (human immunodeficiency virus) replication, may be toxic at higher doses, causing nerve damage to the feet and damage to the pancreas. Researchers at the National Institute of Allergy and Infectious Disease are now ready to begin 'Phase 2' trials, in which the drug's efficacy will be compared to that of AZT, still the only AIDS drug approved for widespread use. Fewer than 30 patients took part in the phase 1 trials but more than 2,500 will take part in phase 2. At the same time, ddI will be made available to patients who cannot tolerate AZT or for whom AZT has been ineffective through a programme administered and funded by Bristol-Myers, the manufacturer of ddI.

With this announcement, the FDA took the first steps towards the much-publicized 'parallel track' mechanism for simultaneous drug testing and distribution. But it remains to be seen whether widespread distribution of ddI will reduce participation in the clinical trials, and there is doubt to over the ethics of approving a drug about which information is still scarce and which may cause serious toxic side-effects.

PERESTROIKA

Selling ideas at the fringe of science

Irkutsk, Siberia

Perestroika has had at least one disconcerting consequence: the emergence in the Soviet Union of fringe science as a force to reckon with. There is now, for example, a cooperative of scientists based in Leningrad whose income is sufficient to support a staff of 20, mostly on the basis of contracts with industrial enterprises and collective farms.

One of the founders of the cooperative, Anatoly Bondarev, once a field theoretician at Leningrad, was in the Baikal district last week with his Irkutsk-based colleague Eugene Mazhous, urging the value of their techniques in insulating Lake Baikal from pollution. They offer activated water as a way of reducing pollution from industrial enterprises such as oil refineries and extrasensory cognition as a way of increasing the yield of agricultural crops.

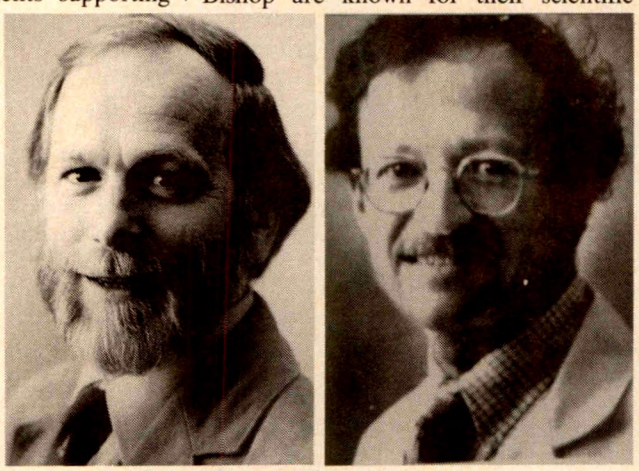
Bondarev says that activated water, made by passing an alternating current through ordinary water, has the property of neutralizing pollutants that may be dissolved in it. As to how activated water differs from ordinary water, he says that its molecular structure retains a pattern of electric dipoles of the kind responsible both for the structure of polywater (a Leningrad invention) and the 'memory of water', coupled with the name of Benveniste.

The agricultural application of extrasensory phenomena is more shadowy, but the starting point is the argument that a farmer about to sow his seeds for the year ahead will first seek to bring himself and his seeds into harmony with the environment in which the seeds must grow. Extrasensory processes can enhance the degree of harmony, it appears. Bondarev and Mazhous say that experiments have shown that crop yields can be increased by 30 per cent even when the use of fertilizers and other chemicals is discontinued.

Publication seems to be a sore point. Bondarev says that "before *perestroika*, our Academy of Sciences was very sceptical of our ideas, and prevented their publication". Now, with the opening of the market in ideas, the cooperative, in the process of being separated from a larger organization called ORKON, is free to make what deals it can with industrial and agricultural enterprises. Bondarev says his cooperative has the support of the Irkutsk Executive Committee, an organ of the regional government, and that talks have been opened with the government of Bolivia about the application of the techniques in Latin America.

The cooperative also believes it will be able to exploit cold thermonuclear fusion. Bondarev says he has several ideas as to how cold-fusion processes might function, but that the cooperative will probably not follow the route chosen by Fleischmann and Pons. John Maddox

PRIZES



Nobel for oncogenes

London

For their discovery that the oncogenes of animal tumour viruses are derived from cellular genes (proto-oncogenes), J. Michael Bishop and Harold Varmus of the University of California, San Francisco (UCSF), have won this year's Nobel Prize in Physiology or Medicine.

In the early 1970s, the prevailing 'oncogene hypothesis' of Robert Huebner and George Todaro postulated that the retroviral-like genes carried in the genomes of most mammalian cells were normally silent but, when activated by carcinogens, contributed to the formation of tumours. A minority view, put forward in particular by Steve Martin, Robin Weiss and Peter Fischinger, held that it was normal cell genes that were activated and were also the origin of the oncogenes of retroviruses.

The seminal experiments supporting the minority view were published in 1976 by Bishop and Varmus, with Dominic Stehelin and Peter Vogt (*Nature* **260,** 170–173; 1976). In it, they provided evidence that DNA closely related to the *src* oncogene of avian sarcoma viruses is present as part of the full complement of chicken genes, and stated that they were testing whether this DNA represented a gene that was involved in either the normal regulation of cell growth and development or in carcinogen-induced tumour formation.

Prizewinners Michael Bishop and Harold Varmus.

A huge accumulation of data since 1976 has generalized the initial finding; almost every tumour virus oncogene is derived from a normal cellular gene. More importantly, these proto-oncogenes are active in normal cells and their products are, indeed, involved in cell signalling, growth and differentiation.

The significance of this conclusion in terms of human cancer was uncertain for some years. But since the early 1980s it has become increasingly clear that the mutation of abnormal activation of certain cellular genes, including many of those that crop up in altered form in tumour viruses, contribute to tumour formation. The first evidence that this was so, emerged when a human tumour gene that was able to induce cancer-like properties in cultured cells turned out to be a mutated version of the oncogenes of the Rous sarcoma virus. Robert Weinberg, in whose laboratory that discovery was made, was tipped in the latest issue of *The Scientist* to share the Nobel prize with Bishop and Varmus, and must, indeed, count himself as unlucky.

Both Bishop and Varmus were born and educated in the United States. Bishop, who is 53, is an MD who took to virology at the National Institutes of Health before moving to UCSF in 1968, where he became professor of microbiology and immunology four years later. He has been director of the George F. Hooper Research Foundation at UCSF since 1981, and continues to pursue research on tumour viruses and proto-oncogenes. Varmus, who will be 50 later this year, has spent the whole of his professional life, sabbaticals apart, at UCSF. Since 1982 he has been professor of biochemistry and biophysics there, and has programmes of research on oncogenes, hepatitis virus and, most recently, human immunodeficiency virus.

Both Harold Varmus and Michael Bishop are known for their scientific writing. The clarity of expression evident in Varmus's papers doubtless owes much to the fact that he graduated in English before turning to medicine and science. Bishop's inimitable style has oncogenes "unleashed" and "incriminated", and not "innocent bystanders or mere pawns in the tumours where they are found". Their lectures in Stockholm in December should make exceptionally good listening.

Peter Newmark

FLOREY INSTITUTE

New director

Sydney

The new director of the Howard Florey Institute of Experimental Physiology and Medicine in Melbourne is to be John Coghlan, who is at present deputy vice-chancellor for research at the University of Melbourne.

Coghlan has been deputy director of the institute since 1976 and will succeed Derek Denton, who retires on 1 January next year. Tania Ewing

HOT FUSION

Next US tokamak in question

Washington

WITH both sides professing to have the best interests of the US nuclear fusion research programme at heart, the fusion physics community and the Office of Energy Research at the Department of Energy (DoE) are displaying a remarkable capacity to derive opposite conclusions from the same set of facts. Physicists want to start work now on the Compact Ignition Tokamak (CIT), a $700-million machine that, by creating a self-sustaining burn of deuterium–tritium plasma confined in a powerful magnetic field, will give them the experience they need to design an energy-producing fusion reactor. But Robert Hunter, DoE's director of energy research, believes that CIT may well fail in its goal of achieving plasma ignition and wants to put CIT to one side while some outstanding problems in plasma physics are resolved.

Enlivening the debate is an unconcealed feeling in the fusion community that Hunter wants to hold back the decades-old magnetic fusion effort in order to allow research on inertial confinement fusion, in which deuterium–tritium fuel pellets are made to implode by blasting them from all sides with laser beams, to catch up. To make legitimate this subversive plan, the physicists say, he asked DoE's Magnetic Fusion Advisory Committee (MFAC) to assemble an expert review panel to assess the chances that CIT would reach ignition, but then installed as chairman of the panel Dr Kim Molvig, an erstwhile theoretical plasma physicist from the Massachusetts Institute of Technology whom Hunter knew to be a sceptic.

To such charges Hunter responds that physicists are already guilty of overselling the present showpiece machine, Princeton's Tokamak Fusion Test Reactor (TFTR), which after seven years has still fallen short of achieving energy break-even (a transient plasma burn which releases as much energy as was needed to create it). TFTR director Harold Furth says that this was never an official goal, although he admits that many physicists "got enthusiastic" and declared that TFTR would reach break-even. But Hunter says that in a 1981 article discussing the next generation of tokamaks, Furth gives TFTR an "energy multiplicity" of about two — twice break-even, in other words.

It was against this acrimonious background that the investigations and oversight subcommittee of the House of Representatives Committee on Science, Space and Technology last week found itself trying to make sense of plasma confinement and the validity of empirical scaling laws. After three days of hearings, in which the subcommittee heard from Furth and other fusion laboratory directors, from Molvig and other representatives of MFAC and the academic fusion community, and from Hunter himself, the entire debate on fusion policy seemed to turn on whether a value of 1.45 for a certain plasma confinement parameter was in accord with expectation or an unjustifiable extrapolation.

The physics of hot plasmas entrained in strong magnetic fields is difficult theoretically as well as experimentally. Experimenters rely on an empirical scaling law that estimates the time for which an 'L-mode' (for lowest quality) plasma of given temperature and density can be held in a given magnetic field.

With fine-tuning, machines such as TFTR and the Joint European Torus (JET) routinely attain plasma confinements better than the L-mode by a factor of two or so. In the present design for CIT, there are two construction phases: in phase I, with low field operation, an enhancement factor of 2.1 would be needed to assure plasma ignition; in phase II, a factor of 1.45 would suffice.

So, the majority of physicists at last week's hearing testified, phase I of CIT would be unlikely to achieve ignition, but in phase II a self-sustaining plasma burn would be almost a certainty.

Only at this rather advanced point in the debate does disagreement set in. In the report of MFAC Panel 22, which Molvig chaired, the statement that an enhancement factor of 1.45 is needed if CIT is to reach ignition is followed by a warning: "without a physics basis for the empirical scaling laws . . . there cannot be great confidence at the present time in obtaining the performance required for ignition". This single sentence, as much as anything else, allowed Hunter to testify that there is "controversy over the scope and design of the fusion programme" and go on to propose that CIT should be delayed while the underlying physics problems were solved.

But according to Fred Ribe, chairman of MFAC itself, the cautionary statement in Panel 22's conclusions is a "molvigism", of which there were at one time many more. Ribe says that Molvig initially wanted to characterize the whole magnetic fusion programme as being "empirically based" but that a lot of "Molvig stuff" was expunged before MFAC passed the Panel 22 report on to Hunter's office. But Ribe felt that some of Molvig's statements, such as the proviso about the likelihood of achieving ignition in CIT, had to be left in, otherwise Molvig would not have accepted the panel's report.

Subcommittee chairman Robert Roe (Democrat, New Jersey) was clearly frustrated by Hunter's assertion that there was controversy over the CIT proposal, when he had previously heard 11 eminent fusion physicists testify in its favour, with only Molvig against an immediate start on the project. And Congressman David Nagle (Democrat, Iowa) established that Hunter's proposal of Molvig as chairman of Panel 22 was unusual: normally, Hunter would ask Ribe to assemble a panel. Ribe told the hearing that he had "acquiesced" in Hunter's suggestion of Molvig, in part because he was pleased by Hunter's personal interest in the fusion programme.

At the end of the three days of the hearing, committee members seemed perplexed that such a sharp disagreement could emerge when everyone, including Molvig and Hunter, agreed that something like CIT was the required next step, and when Hunter reiterated his belief that fusion ignition by the end of the century was the goal DoE should adopt. Perhaps the most clear distinction between the opposing parties was apparent when Roe asked the physicists before him for their assessment of CIT's chances.

With the exception of Molvig, all agreed that ignition was probable, and that in any case not even if the plasma did not ignite, the yield of knowledge would be invaluable. But Hunter's response is that if CIT is being sold to the Congress and to the public as an ignition machine, and fails to ignite, it will join a list of fusion devices which, like TFTR, have not quite lived up to expectations. CIT proponents worry that if the new machine does not move ahead soon, the US fusion programme will fall seriously behind its Japanese and European counterparts; Hunter's fear is that if CIT turns out be another near-miss, the setback will be worse.

David Lindley

NETWORKS

Exploring connections

Paris

WITH financial help from the European Science Foundation (ESF), a new network has been set up to foster European research in 'neuroimmunomodulation', a young and controversial field whose subject is the interconnections between the immune and central nervous systems. Research is aimed at exploring anecdotal evidence that, for example, depressive patients are more susceptible to physical illness. According to the proposal sent to ESF, the United States is stealing the lead "because of its ability promptly to mobilize human and material resources to explore new and promising areas of research". An ESF grant of FF590,000 ($91,000) will be used to organize workshops and discussion meetings, once the network is launched on 15 October.

Peter Coles

NATURAL HISTORY MUSEUM

A London dinosaur evolves

London

THE Natural History Museum in London hopes to raise £5 million over the next five years for a new series of permanent exhibitions to take it into the next century. The first, on ecology, is scheduled to open at the end of 1990. The money will come from private sponsorship and will be managed by a development trust, launched on 11 October. And the museum is making wider efforts to change its fusty image: an education trip to Disney World in Florida last month is likely to cause a permanent change in the museum's organization and outlook.

Staff returning from the customer care courses at Disney World speak of lessons learned with the kind of conviction normally associated with religious conversion. But many middle-ranking and junior researchers remain unconvinced.

Unlike Disney World, where customer service is based on a clear set of objectives whose success is a matter of corporate pride, the museum, part of the British Civil Service, has had no clear policy on the care of visitors. Some changes have been made — £8.3 million has been invested in new facilities such as a centre for schoolchildren and a spacious cafeteria but the purpose of the Disney trip was to focus vague feelings of a need for change into a plan of attack.

The fact that 17 people went to Florida at public expense, rather than two or three, has come in for criticism, especially from researchers at the museum. Chris Metcalfe, the museum's head of communications, contends that 17 is a small

number, as more than 100 museum staff members are directly involved in visitor care, and the museum's associate director, John Peake argues that £30,000 spent on the trip will be money well spent if staff can then justify the investment needed to improve visitor facilities.

Neil Chalmers' appointment last year as director (see *Nature* **336**, 707; 1988) has accelerated the pace of change at the museum. Several years earlier, the museum had commissioned design consultants Wolff Olins to make suggestions for improvements. Returning this year for more detailed work, the firm found an antiquated institution full of mutual suspicion and a profound lack of communication between staff members.

The museum itself may be the problem. Designed as a Gothic cathedral to knowledge by Alfred Waterhouse and opened to the public on Easter Monday 1881, the museum behind the scenes is a maze of rooms, passages and locked doors that impedes communication and emphasizes divisions. "The whole institution is about not letting anyone know anything about anything", says consultant Wally Olins, a symptom common to other organizations of his experience housed in Waterhouse buildings, which he describes as "murderous... impossible to work in".

Museum staff take the building for granted but recognize that communication problems are serious. Metcalfe, one of Wolff Olins' original design team, joined the museum last November and acknowledges the suspicion fostered by lack of communication as "a key factor to be managed". But efforts to get people involved in the running of the museum are not helped by a workforce that feels its needs have been ignored for long enough.

Research frustrations too may stem from the fact that nobody has thought about the function of a museum with the deliberation that Disney applies to corporate style. Researchers who feel unrecognized and disregarded need, says Olins, to look outwards: instead of seeing themselves as stewards in a "cathedral with 67 million specimens", they should emphasize their role as a unique team with marketable expertise to offer. But many researchers identify with the "cathedral" image and do not see a need to change.

Even small modifications are proving difficult. A new impressionistic logo of a branching tree and the change of name from the "British Museum (Natural History)" to "The Natural History Museum" have excited controversy, largely because of the presumption implied by the definite article. Researchers do not like the change, despite the fact that some overseas researchers still confuse the museum, in South Kensington, with the British Museum in Bloomsbury, another part of central London.

Such resistance hardly augurs well for Olins' grand vision of grouping the many museums, colleges and leisure facilities of South Kensington into "a beautiful, single campus". But despite the many misgivings expressed by researchers, Chalmers still stands by his commitment to research. "Science is enormously important to us: I can't say that strongly enough."

Henry Gee

AUSTRIAN SCIENCE

First five Doppler laboratories launched

Vienna

AUSTRIAN industry took a step towards improving its access to basic research on 28 September when it launched the first five of an estimated 20 'Christian Doppler Laboratories' in fields of potential commercial interest, ranging from biotechnology to expert systems. The project is sponsored by the Austrian nationalized industry Österreichische Industrieholding AG (ÖIAG), subsidiaries of which produce steel, aluminium and chemicals as well as electronic and mechanical components. The rest of the laboratories will be chosen by 1991.

The laboratories, to be located at universities or existing research institutions, are named after the Austrian physicist and mathematician Christian Andreas Doppler (1803–53), eponymous discoverer of the effect by which relative motion between a source of sound waves and a listener alters the perceived pitch of sound. ÖIAG will give each institution up to 3 million Austrian shillings ($225,000) in one-to-five-year grants, hoping to attract good young researchers to work with the senior scientists around whom each Doppler Laboratory will be organized.

ÖIAG chairman Hugo Michael Sekyra pointed out at the opening ceremony that the company, which is still recovering from a bankruptcy in 1986, invests only ASch 2,600 million a year in research despite an annual turnover of ASch 150,000 million. Sekyra wants to increase research spending to ASch 4,000 million over the next five years; corporate research planning will be aided by the participation of Doppler laboratory directors.

The new investment is seen as sorely needed in a country that invests only 1.3 per cent of its gross domestic product in research, much less than the 2.5 to 3 per cent investments of other Western nations. The Austrian government now seems destined not to achieve its 1987 promise to increase research investment to 1.5 per cent by 1990.

ÖIAG's determination to raise its standards was illustrated by Sekyra's stated intention to go outside Austria if necessary to set up Doppler laboratories. Going abroad would be unpopular, but ÖIAG might be forced to do so in fields such as materials science. Steven Dickman

ENVIRONMENT

New plan for Mono Lake

San Francisco

MONO Lake, in northern California, is a unique ecological site, with hundreds of migratory bird species attracted to the algae and brine shrimp that thrive in its alkaline waters, and a tourist attraction too, drawing hundreds of thousands of visitors every year to see the spectacular limestone tufa towers as well as the wildlife. But since 1941 the level of the lake has fallen 41 feet, as the city of Los Angeles has drawn drinking water from four of the five major feeder streams, and the increasing alkalinity threatens to kill the lake. In an attempt to help resolve one of California's most bitterly fought environmental battles, a bill signed into law late last month offers Los Angeles up to $60 million if it can find its water elsewhere.

This rich diversity is threatened by the loss of water; the demands of Los Angeles have led to a halving of the lake's volume and a doubling of its salinity. Partial exposure of the alkali-covered lake bed has, according to some, produced a toxic dust laced with arsenic and selenium.

The new legislation will not by itself save the lake, but was endorsed by all parties in the fight and marks a new and potentially pivotal state presence in the decade-long dispute.

Martha Davis, executive director of the Mono Lake Committee, praised the bill for its provision of an incentive for finding alternative sources of water.

Given Los Angeles' current annual water consumption, it has been estimated that the lake's ecosystem will collapse early in the next century. But the city, which receives about 17 per cent of its water from the Mono Lake stream diversions, disputes this and other conclusions.

Several lawsuits surround the Mono Lake controversy, but all have been suspended while the state of California undertakes an exhaustive review, estimated to be finished in late 1993, of the water licences.

The state's offer of $60 million is designed to coincide with this effort, and is good only if a compromise solution is reached by January 1994. Although Los Angeles supports the legislation, the money is probably a drop in the ocean compared to what is needed. Mitchell Kodama, manager of Mono Basin issues for the Los Angeles Department of Water and Power, guesses that billions of dollars over the next 50 years will be needed to find new water and power supplies, and says that resolving the issue will be impractical without federal assistance, something that Senator Pete Wilson (Republican, California) is expected to propose soon.

Robert Buderi

SOVIET SCIENCE

Industry must help science

London

SOVIET industry must take responsibility for helping to solve scientific and technical problems, Deputy Premier Lev Voronin told the Supreme Soviet at the end of last month. Presenting the draft budget for 1990, he rebuked industrial managers for having failed to respond to recent economic reforms. The restructuring of the Soviet economy calls for enterprises to channel their profits into the development and introduction of new, more productive technologies. But the managers, Voronin said, are actually showing less interest in this field.

The old system of central planning with its rigid targets imposed financial penalties on enterprises which closed down temporarily for retooling, even if the long-term result was greater productivity and higher-quality output. As a result, at the end of the Brezhnev era, there was an ever-growing time gap between technological development and its innovation in industry, sometimes of 10 years or more. Furthermore, the subordination of the major part of the applied research sector to the various industrial ministries meant that much work was duplicated and made interdisciplinary collaboration between institutes under different ministries virtually impossible. A side-effect of the subordination of these 'branch' institutes to their ministries, and hence to a specific industry, was the extremely narrow professional specialization of young scientists.

Mr Mikhail Gorbachev's solution was to advocate the establishment of 'inter-branch scientific and technical complexes (IBSTCs) to draw together industry and technological research and to break down the bureaucratic barriers to cooperation. Implementing this proposal has proved a slow task.

The Soviet leadership is still firmly committed to these complexes which, Voronin said, will be responsible for a "substantial volume" of the "state order" for research — that is, the priority research areas still controlled by the central planners. In spite of the delegation of much problem-solving research to the decision of industrial managers, the state sector still has a substantial role to play. During the next year, Voronin said, 59 new testing and pilot-production facilities will be commissioned to "consolidate the material base of scientific organizations fulfilling the state programmes".

Not all Soviet scientists, however, share Gorbachev's enthusiasm for the IBSTCs. For many years, Soviet technologists have found themselves on the losing end of a 'two cultures' debate with the 'fundamental' researchers. Subordination to the industrial ministries, the latter said, has made applied research the "handmaiden of bureaucracy". In a counter-attack just published in *Priroda*, the popular-science monthly of the Soviet Academy of Sciences, Academician Lev Tauson, director of the Vinogradov Geophysical Institute of the Siberian Branch of the Soviet Academy of Sciences, called for the establishment of a new Academy of Technical Sciences, analogous to the existing agricultural and medical academies. Tauson argued that ministries are interested in short-term solutions to specific problems. An independent technology academy, he said, would cost relatively little to establish, because it would take over the existing 'branch' institutes and the applied science institutes of the Academy of Sciences, which would then be left free to pursue fundamental research. Such an academy would be able to see through promising new developments from the initial concept to pilot production. Unfortunately, he admitted, the idea had little chance of success, because the State Committee of Science and Technology still considers that the Soviet Union's industrial problems can best be solved by concentrating financial support on narrowly target-orientated projects and in making 'academic' science ever more utilitarian.

Vera Rich

NEUROSCIENCE

A new line in 'neurocomputers'

London

AT a conference in Moscow, experts in nonlinear studies decided last month to establish an international centre in Pushchino, Soviet Union, to coordinate work in the development of neurocomputers. The Moscow workshop, Neurocomputers and Attention, was organized by the Academy of Sciences of the USSR and the Centre for Nonlinear Studies (CNLS) of the University of Leeds with the aim of working out a coherent strategy for modelling higher brain functions and designing large-scale neurocomputers.

According to Arun Holden, director of the CNLS, participants at the meeting were attempting to bridge the gap between attention modelling and neurobiology. The Soviets introduced the concept of an 'attentional neurocomputer', and although most Western scientists regarded the idea as a good one, they did not think Soviet technology was sophisticated enough to realize it. The planned international centre was decided upon as a way of combining the different Soviet and US approaches, which Holden believes should greatly speed up the development of a neurocomputer.

Ben Webb

WEST GERMAN RESEARCH

Berlin row threatens support

Munich

AN apparently parochial row in the West German Bundestag (parliament) over research support for West Berlin may turn out to have wider implications. In a dispute over the licensing of a nuclear research reactor at the Hahn-Meitner Institute (HMI), the only federally financed Large Research Establishment in West Berlin, the conservative coalition in Bonn may have found an issue that could split the six-month-old Social Democratic (SPD)–Green coalition in West Berlin's governing body, the Senate.

The newly renovated reactor will serve primarily as a neutron source for physicists, chemists and biologists, mostly from outside HMI. Of the total cost of DM 150 million ($79 million), 90 per cent was paid by the Research Ministry. In a letter sent on 22 September, West Berlin Governing Mayor Walter Momper (SPD) assured Research Minister Heinz Riesenhuber (Christian Democrat, CDU) that the reactor would be licensed by May 1990, assuming that all technical details (such as signing a contract with the United States for radioactive waste disposal) could be cleared up by then. He said he would be prepared, if necessary, to issue an executive order (*Sofortvollzug*) to eliminate bureaucratic delays.

But Bundestag member Christian Lenzer (CDU) openly doubted Momper's word, saying he expected the licensing procedure to drag on indefinitely, as in the case of the completed but unlicensed fast breeder reactor at Kalkar. The Bundestag science and technology committee then threatened to cut off the financing of new projects in West Berlin unless the reactor licensing moved ahead. The committee's conservative majority demanded a "clear, reliable course" from the West Berlin government.

Although its rhetoric is critical of science and technology — for example, calling for more studies of the impact of technology on society — the SPD–Green government has not yet taken any strong positions against science. In closing the academy, Momper said the money would be better invested in improving conditions at overcrowded universities. But, with elections a year away, the SPD and the Greens have sent out conflicting messages about issues such as nuclear power.

Social Democrats in the Bundestag attacked the committee's threat in a tumultuous plenary debate. Edelgard Bulmahn (SPD) charged the conservative parties with "unprecedented interference" in the internal affairs of the *Land* (state) of West Berlin tantamount to "blackmail", which could have "lasting consequences." And the issue could even break up the SPD–Green coalition.

If Momper makes good his promise, it will put Environment Senator Michaela Schreyer of the *Alternative Liste* (AL), the local branch of the Greens, in the unaccustomed and difficult position of having to sign a reactor licence. The distinction between research and power reactors is not seen as relevant by the many AL members who oppose the reactor.

Although HMI welcomed the pressure from Bonn, saying that it was "very useful" that Momper had now set a deadline for licensing, the heavy-handed approach of the conservative coalition in the Bundestag offended West Berlin industry, traditionally supporters of conservative causes. The Chamber of Commerce and Industry (IHK in German) warned that the committee's threat may drive new investment away from the city.

West Berlin is dependent on the Bonn government for most of its research support, as it is, in fact, for 52 per cent of its overall budget. It receives 6 per cent of all federal research funds, although it has only 3.1 per cent of the total population of West Germany. Research, basic and applied, is an economic lifeline for the city.

Steven Dickman

TECHNOLOGY TRANSFER

Adviser learns Japanese

Washington

THE new director of the US Office of Science and Technology Policy (OSTP), Allan Bromley, admitted last week that the system for transferring technology from federal laboratories to industry was beset by "byzantine complexities" and promised that improving it would be high on his agenda for the 1990s. His plans include setting up a new industrial technology section within the OSTP with a powerful presidentially appointed director, and he suggested that both government and industry had a lot to learn from the Japanese.

Under a grilling by members of the House of Representatives subcommittee on regulation, business opportunities and energy, Bromley said he was "committed to emphasizing the 'T' in OSTP" much more than his predecessors, and suggested that the United States adopt some features of the Japanese system, the success of which he attributed to "putting basic researchers, development engineers, manufacturing engineers and materials experts in groups, stirring briskly, and then assuring them of stable support in their pursuit of broadly specified goals".

The features that make the Japanese system work, he said, are: the targeting of key technologies for special attention; a long-term commitment of money and people "even if results are slow in coming or don't come at all"; cooperation between industry, government and universities; collaboration between basic researchers, development engineers and experts in manufacturing and materials; and the training of a large cadre of highly-specialized "supertechnicians".

But in the United States, Bromley said, individual companies waste expertise, time and money reinventing basic technologies, and the division between research and manufacturing means that US-designed products may be intrinsically difficult to make, and thus expensive. And the lack of "supertechnicians" means US companies must often go to Japan for samples of materials invented and developed in the United States. Bromley stressed, however, that he did not advocate "slavishly copying" the Japanese model, but rather selecting parts of it.

The consequences of the poor US system were laid out in a report by the subcommittee staff, which calculated that the return to the government in 1988 from licensing of federal inventions and discoveries amounted to only 0.00005 per cent of the research investment. It also complained that federal laboratories are ignoring new technology transfer laws and called for a top-level administration executive to take responsibility for monitoring their technology transfer efforts.

The report was endorsed by Robert Brumley, former general counsel for the Commerce Department, who said that "the problem with the federal technology transfer program is that no-one understands it".

While working at the Commerce Department on technology transfer related to the space station, Brumley attempted to invoke the Federal Technology Transfer Act of 1986 to force the government to increase its technology transfer efforts and found that "not one member participating either from the National Aeronautics and Space Administration, the Department of Defense, the State Department, the Office of Management and Budget or the White House" was aware of the provisions of the act.

James Ling, a science adviser to former president Ronald Reagan, blamed federal officials for taking the attitude that "every company is trying to 'rip off' the government". Unless the situation improves, he proposes taking radical steps: "If we can't get more out of these activities we should scale them back or even shut them down", because they are tying up resources that could be better used in the private sector.

Christine McGourty

Problems at Max Planck

SIR—I would like to respond to your article on the structural problems of the Max Planck Society (MPS) (*Nature* **340**; 335; 1989).

The MPS does not consist only of directors and slaves; there is also a sizeable number of middle-rank employees (equivalent to tenured associate professors in US universities) whose scientific reputation is independent of the director. They run their own groups and programmes, with much of their support coming from outside grants. Many of them have come back to West Germany from good overseas posts, hoping to use their positions either to move up within the MPS or to obtain a university professorship. To the frustration of many of them, (1) the low level of institutional recognition given to them makes a career within MPS highly unlikely, and (2) the congestion at the top of West German universities, both in terms of available professorships and resources, seriously limits their flexibility. At present, these group leaders face the same dark future as other employees left behind when a director retires.

Many of the current problems of the MPS could be solved if the society would develop an attractive career system for younger scientists similar to that of tenure-track positions in US universities. The independence of scientists should parallel their ability to carry out independent research, their motivation should be fostered by a reasonable outlook and institutional recognition, and the MPS should develop a system of internal competition for resources. A fresh approach is necessary in which the present privileges and endowments of MPS directors are more reasonably divided between all the members of the MPS community. The hope is with the new generation of directors but a chorus of voices is required in order to be heard.

ALFRED MAELICKE

Max-Planck-Institut für Ernährungsphysiologie, Rheinlanddamm 201, D-4600 Dortmund 1, FRG

SIR—The article on the Max-Planck Society (MPS) highlights one of the structural problems this society has. In addition, there is at least one other problem. The MPS has chosen to employ particularly able scientists on tenured contracts equivalent to those of middle-rank professor at the universities. Their number is about 200 and thus similar to that of the directors. Many of them function as group leaders on projects that are independent although often related to that of the director, and always dependent on him for resources. This group of scientists contribute greatly to the reputation of the MPS. Yet, as the MPS has failed to make provision for such groups as independent units, the society sees their existence as a private arrangement with the director, with the consequence that resources will be cut off when the director retires. These colleagues have been chosen on their scientific merit and in many cases are expected to run a group, so it is a slap in the face that their scientific career in the MPS should essentially be terminated with that of the director. The MPS recognizes as units only departments with directors as heads. Rare exceptions are the groups for junior scientists established on a five-year basis. Although there might have been a justification for this hierarchical structure in earlier days, it is inadequate for a research organization nowadays. It should be adjusted to present-day requirements by giving autonomy to the *de facto* existing mid-level positions. The MPS would benefit from such a change by a decrease in size of departments and the creation of a livelier, more stimulating atmosphere in the institutes.

F. ECKSTEIN

Reason to write

SIR—As a scientist and a member of the human rights group Amnesty International, I would like to bring to the attention of the scientific community one of the many human stories that underlie the brutal repression in China in the past several months. *Nature* has reported on the events in China, and on some of the arrests that have occurred in the Chinese scientific community (for example **340**, 174; 1989). Among those arrested in the crackdown was Yang Wei.

Yang Wei was one of the many Chinese students to go abroad in the past ten years, spending several years as a molecular biology student at the University of Arizona. Many of us have had the privilege of meeting such students. As they learned about science, we watched as they adapted to the West and learned about the freedoms we enjoy.

Yang Wei was unfortunate enough to have been at home for a visit during the earlier round of student demonstrations, and he was among those arrested in January 1987 and imprisoned. During his imprisonment he was adopted as a prisoner of conscience by Amnesty International. His two-year prison term ended in January this year, and he was awaiting permission to return to his studies in the United States, and to rejoin his wife, also a student here. These plans came to nothing on 19 July, when he was arrested again—allegedly for involvement in the recent round of demonstrations.

Any of the thousands of Chinese students abroad could be Yang Wei, imprisoned for speaking out, something we had taught them to do, both directly and by example. Seeking out the truth and speaking it underlie the ideal of scientific enterprise. We cannot abandon our colleagues in China who are now being punished for speaking the truth. One way to remember them is to write to Prime Minister Li Peng (Guowuyan, Beijingshi/People's Republic of China) on behalf of Yang Wei, expressing concern at the reports of arbitrary arrests such as his. We must remind the Chinese leaders that we will not forget the events of June or their aftermath.

Pitt not Penn

SIR—A leading article on "Conflicts of interest" (*Nature* **340**, 664; 1989) commented on "the dispute that has now come to light at the University of Pennsylvania". However, it is stated on page 668 that the dispute on conflicts of interest is at the University of Pittsburgh. Please note that the University of Pennsylvania, named for William Penn, is the one founded by Benjamin Franklin in 1740 and is beginning its 250th anniversary celebrations. The University of Pittsburgh, which has the dispute, was named for William Pitt the Elder, and was chartered in 1787. Although it is a university *in* Pennsylvania, it is not the University *of* Pennsylvania and is more than 300 miles away from here.

ROBERT E. DAVIES

University of Pennsylvania, Philadelphia, Pennsylvania 19104, USA

Women in physics

SIR—Only 130 out of 1,302 doctorates granted in physics in the United States in 1988 went to women (*Nature* **340**, 417; 1989).

In the same issue, you wrote "By now, of course, every schoolboy knows that the quintessential point in space-time is the occasion of the Big Bang . . ." (*Nature* **340**, 425; 1989).

Thank you for pointing out that the underrepresentation of females in phys begins at an early age.

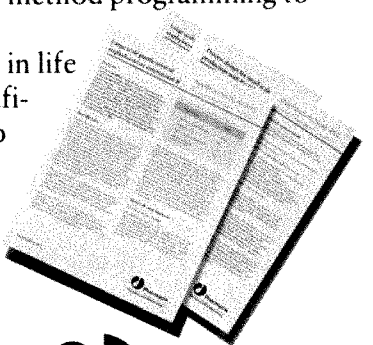
Develop with BioPilot

BioPilot™ brings power and purpose to process development. As fast, as familiar, and as flexible as FPLC®, but with more scale-up power and a wider choice of columns, BioPilot delivers what every hard-working project group needs – speed and versatility.

When the pressure is on, BioPilot helps you quickly develop optimized methods, run scale-up studies and prepare for trouble-free transfer to production on systems like BioProcess™.

When you need small amounts of material for clinical trials or sale, BioPilot produces multi-gram quantities of highly pure product – by the hour.



And when more than one project is urgent (which it usually is), BioPilot purifies what you want, how you want, where you want.

Monoclonal antibodies, research enzymes or recombinant proteins. By gel filtration, ion exchange, affinity or hydrophobic interaction chromatography. With laboratory or production columns. On your bench, or in the cold or clean room.

But however you use BioPilot, you won't have to baby-sit it. As a fully automated, multi-column, multi-cycle chromatography system, operational flexibility is programmed at the touch of the keyboard and executed at the turn of a motorized valve.

Furthermore, a new control software option now dramatically improves the way you work with BioPilot – from method programming to the written report.

So if your purpose in life includes turning purification protocols into purified products, ask for our new Application Note pack. It makes a powerful case for BioPilot.

BioPilot – companies develop with it.

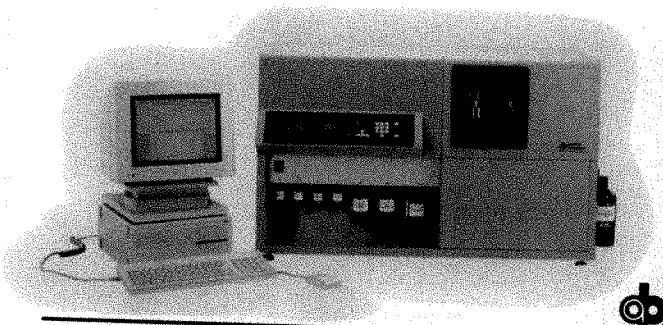
NEW

Model 473A Sequencing System

ProteinSequencing in the 1990's

Get all the sequencing capabilities you need in one system: your choice of Pulsed Liquid™ or gas-phase chemistry, microgradient PTH amino acid analysis, advanced data handling on the Macintosh® computer, and the expertise of Applied Biosystems.

SENSITIVITY



- Low picomole sensitivity
- Low volume reaction cartridge and conversion flask
- On-line microbore LC for PTH Analysis
- Injection system allows up to 100% sample to be injected

FLEXIBILITY

- Use any sample support matrix
- Extra bottle position for chemical versatility

DATA ANALYSIS

- Peak Integration
- Amino acid histogram plots
- Cycle yield plots
- Repetitive yield plots
- Multiple cycle overlays
- Cycle modification and optimization
- Access to intermediate results
- Powerful Macintosh® graphics

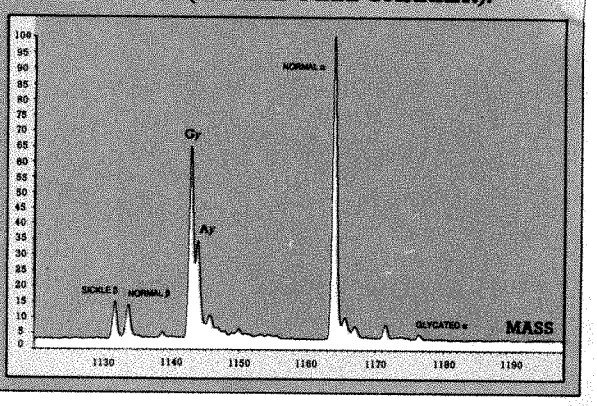
If only weighing biomolecules accurately was this easy.

It is with the VG BIO-Q

— a new mass spectrometer specifically designed for the molecular weight determination and structural elucidation of biomolecules.

For the first time biochemists can achieve an accuracy of better than 0.01%. And with a total analysis time under five minutes, sample throughput is many times greater than with earlier techniques.



Even mixtures, such as the globin chains from normal and aberrant haemoglobins, present no problem.

So whether it's large proteins like enzymes, nucleotides, or smaller molecules such as pharmacologically active peptides the VG BIO-Q offers fast, accurate analysis.

HUMAN FOETAL HAEMOGLOBIN (SICKLE CELL CARRIER).

Globin	M.W.	Error
Sickle β	15838.2	+1.0
Normal β	15866.6	−0.6
Gγ	15995.8	+0.5
Aγ	16009.6	+0.3

Baikal centre takes step forward

The project to found an international research centre on Lake Baikal took another modest step forward last week, but there remains a great deal to be done.

Listvianka (on Lake Baikal)

How do you set about founding an international research centre the like of which has not been seen before? That is the question with which a group of Soviet and overseas limnologists wrestled last week. They got as far as signing a declaration of intent, but the hard work still lies ahead.

The project to found an international research centre on the shores of Lake Baikal is nevertheless breathtaking in its audacity. The idea is to create within the previously closed Soviet Union a centre in whose scientific managment foreign members will have the decisive voice. Most probably, the director will also be from overseas, although there will be a Soviet executive director who will function as a legally responsible accounting officer.

The prime mover is Dr M. A. Grachev, a molecular biologist who is now director of the Limnological Institute of Irkutsk, the nearest city, but he has the solid backing of Academician Valentin A. Keptug, president of the semi-autonomous Siberian branch of the Soviet Academy of Sciences. The Siberian branch has offered a down payment of 5 million roubles and at least matching funds thereafter.

Lake Baikal's claims on public attention are well-known (see, for example, *Nature* **329,** 802; 1987 and **337,** 111; 1989). It holds perhaps a fifth of the total fresh water on the surface of the Earth, and appears to be in its pristine state, a couple of paper-pulp plants on the southern shore notwithstanding. Unlike most other deep lakes, Baikal retains oxygen even at its greatest depth of 1,700 metres. There is a staggering array of endemic flora and fauna, including a population of 20,000 seals adapted not merely to fresh water but to life on the surface of the couple of metres of ice covering the lake in winter. Yet the origins of those forms, as of the lake itself, remain mostly a puzzle.

Last week's proceedings fell into two parts. During waking hours, there was a symposium planned as a survey of the opportunities Lake Baikal offers, happily coinciding with the centenary of the birth of G. Yu. Vereshchagin, one of the pioneers of research at Lake Baikal after whom the largest of the lake's seven research vessels is named.

Evenings were given over to politicking, mostly the discussion of a draft charter for the centre and the draft of a more detailed agreement that will determine how the centre operates. There was the usual flurry of late-night and inexpert typing. The general opinion seems to be that it is too soon to draft a final constitution for the centre. There is some hope that that may be possible by next May (when the ice will have gone), but that may be frustrated.

But there is a sense in which the centre is already a going concern. Almost a score of joint projects have been mounted in the past two years under the aegis of the Limnological Institute. The usual pattern is that there will be an agreement to carry out some investigation between an overseas group and one recruited in the Soviet Union, not necessarily from Irkutsk. The benefits for overseas groups are considerable — the Soviet side provides free travel from Moscow and free accommodation, while the Limnological Institute puts its seven research vessels at the disposal of the international groups.

So why not let these arrangements multiply naturally? That may be what will happen. But the Soviet side would like to see the programme grow faster if that can be done respectably. Despite a century's desultory research, much of it published at huge length in Russian-language monographs, too little is known about the present state of Lake Baikal. There is even room for argument, for example, about the water-balance of the lake, with thousands of inlets but only one outlet, the Angara; some believe that a credible water balance requires subterranean input.

The origin of Lake Baikal, more than 700 km long, is similarly in dispute. Although it closely resembles the great Rift Valley lakes of East Africa, there are only the sketchiest signs that it is part of a larger system of faulting and subsidence. But mounting a deep seismic survey of the whole Baikal region will be a formidable undertaking, requiring years of effort.

Meanwhile, there are more practical difficulties to contend with. The Limnological Institute, the centre-in-waiting, is more than 70 km away. There is an urgent need for workshop and laboratory space near the lake itself, together with dormitories in which researchers can sleep. So the Siberian branch hopes that it can persuade its potential research partners to contribute towards the cost of these facilities, perhaps between $15 million and $20 million. One scheme floated last week is that there should be three classes of members, with so-called founder members defined as those able to contribute $500,000 of capital at the outset being alone entitled to sit on the board of management of the centre. One unique condition attached to these contributions is that, if the centre should cease to operate, the funds would be returned.

The formula does not appeal to everybody. One difficulty is that university research groups could not contribute funds on such a scale out of their initial contributions from their governments or government grant-making agencies, which would be unwilling to delegate the prestige of making such a large and conspicuous grant to a mere grant-applicant. And that would lead to an international treaty between governments rather than to a research-led organization of the kind intended. Koptag says that "we have some experience of this kind of organization", but it may be a more serious handicap that the Soviet Union does not appreciate that the apparently uniformly well-equipped research enterprise in the West rests on tooth-and-nail competition for funds.

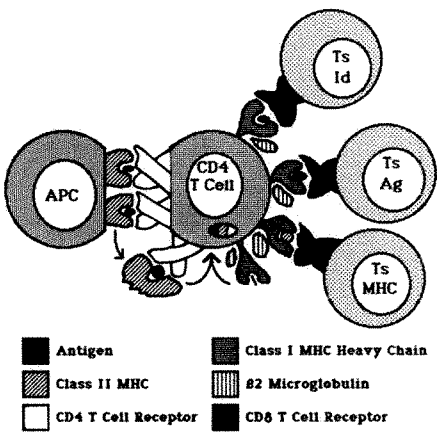
There are other problems, talked about less openly last week. One danger is that people may be tempted to repeat on Lake Baikal studies already carried out elsewhere, without much thought of what they mean. Grachev, for one, would prefer that the final constitution of the international centre were delayed than that it should spawn a flood of second-rate science.

So there seems enough genuine enthusiasm to ensure that something will have happened by next May. The letter of intent commits its signatories only to do what they can to realize that goal. The signatories include representatives of several US research groups, two delegates from China (who came by train), and people from Canada, Sweden and West Germany. The Royal Society (of London), which has a committee working on the project, was formally represented by a delegation, but the smaller Belgian deleation signed an interim agreement with the Siberian branch for a comparative study of Baikal and the East African rift lakes, chiefly Tanganyika and Malawi, on the understanding that it will be subsumed in the agreement to found a centre when, formally, there is one. It will be a shame if this enthusiasm comes to nothing.

John Maddox

AUTOIMMUNE DISEASE

Immunotherapy by peptides?



Charles A. Janeway

AUTOIMMUNE diseases occur when T lymphocytes become persistently activated by self antigens. Like all antigens recognized by T cells, these consist of a peptide fragment, which is held in the cleft of a major histocompatibility complex (MHC) molecule (class I MHC in the case of CD8 T cells and class II in the case of CD4 cells). Thus, one approach to therapy of autoimmune disease is to provide a substitute peptide that can remove the stimulus that is turning on the T-cell response. An alternative approach is suggested by recent studies showing homogeneity in the receptors of the T cells generating several autoimmune diseases. Peptides based on the sequence of the receptor on such T cells might immunize an animal against autoimmunity, as shown in the report of Vandenbark *et al.* on page 541 of this issue[1]. These contrasting approaches to peptide immunotherapy raise several interesting questions about the autoimmune process and its specific inhibition.

Currently, one of the best characterized autoimmune diseases is experimental allergic encephalomyelitis (EAE), induced in mice or rats by injection of myelin basic protein (MBP) in strong adjuvants. In H-2^u mice, the disease is mediated by CD4 T cells recognizing the acetylated amino-terminal nonapeptide (Ac1–9) of MBP bound to the class II I-A^u molecule; in rats, a different peptide of MBP is recognized. T cells that can experimentally transfer EAE from one animal to another have been shown in both mice and rats to have receptors whose variable domains are encoded by a very limited, and highly homologous, set of V-region gene segments. With the detailed characterization of both the autoantigenic ligand and the T-cell receptor that recognizes that ligand in EAE, it has been possible to design rational peptide-based immunotherapies. Initial results, although promising, raise more questions than answers.

Two groups have used synthetic peptides to explore the recognition of Ac1–9 by disease-inducing or encephalitogenic cloned T-cell lines[2,3]. Both find that peptides modified at position 4 can bind class II MHC molecules much more strongly than the native peptide, potently stimulating encephalitogenic clones but, surprisingly, not inducing disease *in vivo*. Indeed, co-immunization with the native and amino-acid-4 modified peptides prevents the normal induction of EAE. The same is true of peptides modified at both amino acids 3 and 4, which bind class II MHC molecules strongly, but no longer interact with the T-cell receptor on encephalitogenic clones.

Whereas the rationale underlying this approach is to inhibit binding of autoantigenic peptides to class II MHC molecules, there is presently no evidence that this is the mechanism by which the EAE is prevented. It is also possible that the peptides are pre-empting the immune response by generating suppressor T cells or CD4 T cells of a distinct and nonpathogenic functional type, particulary in the case of the position-4 substitutions that retain antigenicity but lose the ability to induce disease. The class of CD4 T cells

An antigen-presenting cell (APC) stimulates a CD4 T cell, whose T-cell receptor binds the peptide–class II MHC complex, somehow detaches it from the APC and internalizes it via endosomes, where the class II MHC molecule and the T-cell receptor are degraded, and the peptide is released. After binding to class I MHC molecules, which are believed to recycle through endosomes in T cells, the peptide is in turn presented to CD8 suppressor T cells specific for peptides derived from the T-cell receptor (Ts Id), the MHC molecule (Ts MHC) or the antigen itself (Ts Ag). The CD8 T cells serve to regulate the activity of the CD4 T cell. Immunization with T-cell receptor peptide would stimulate the Ts Id in this scheme.

activated in several *in vivo* immune responses has been shown to have a strong influence on biological consequences[4,5].

This form of peptide immunotherapy is, at least in concept, essentially passive. Because the exogenous peptide must compete with endogenous peptides for the MHC peptide-binding site, it must be continuously supplied to avoid induction of the autoimmune response.

An alternative approach is deliberately to vaccinate against the autoreactive T cell. This approach was pioneered by Irun Cohen and co-workers at the Weizmann Institute, who in 1981 showed that rats given attenuated encephalitogenic cloned T cells become immunized against EAE[6]. They postulated that the target for this vaccination was the T-cell receptor. The recent demonstration in both rats and mice that encephalitogenic cloned T-cell lines have very restricted receptor variability, and the recent successful immunotherapy of EAE with monoclonal antibodies to shared T-cell receptor epitopes, are consistent with this view[7]. Following this lead, Vandenbark *et al.*[1] and Howell, Brostoff and colleagues[8] have now successfully prevented EAE in rats by immunizing them with synthetic T-cell receptor peptides emulsified in adjuvant. Interestingly, while Vandenbark *et al.* use a peptide from the CDR2 region of the receptor β-chain, Howell *et al.* use a peptide from the VDJβ region. Vandenbark *et al.* have gone on to show that CD8 T cells that respond to the receptor peptide presented by class I MHC molecules can transfer protection against EAE. These studies show quite conclusively that suppressive T cells can turn off the autoimmune response that causes EAE.

This active approach of turning off EAE by T-cell-receptor peptide immunization — like the passive approach that uses blocking peptides to prevent the autoimmune response from being turned on — raises numerous questions. The first of these is whether the active approach will be feasible in other autoimmune diseases. To be successful, the T cells causing the disease must be very homogeneous. There is evidence that this condition is met in experimental autoimmune diabetes[9] as well as in human rheumatoid arthritis[10] and multiple sclerosis[11], for which EAE is considered a model, although in no case is this settled. In addition, the precise structure of the T-cell receptor must be known in each disease. If these obstacles can be overcome, this form of active immunotherapy would be highly attractive, as it requires only a vaccinating dose of peptide and not continuous treatment, and it offers the possibility of specific dominant suppression of a continuing immune response, which is always a difficult goal to achieve.

Perhaps the most interesting question raised by the present experiments is the mechanism by which the suppressive T cells recognize their specific target. Most peptide immunogens stimulate the CD4 T cells that recognize antigen presented by class II MHC molecules, but Vandenbark *et al.* have stimulated CD8 T cells that are class I MHC restricted. The target cell is presumably recognized with the same specificity. While it has been shown — most dramatically by Townsend *et al.* in a recent article in *Nature*[12] — that exogenous peptides can bind effectively to class I MHC molecules, the stimulation of CD8 T cells by extrinsic peptide immunization has been a rarity. This suggests that novel mechanisms may be operating in the Vandenbark *et al.* system.

T-cell-receptor peptides could arise by intracellular degradation and associate with class I MHC molecules. A more novel and interesting explanation for

these results is that T cells, unlike conventional antigen-presenting cells, internalize class I MHC molecules via the endocytic pathway[13], where they can bind peptides generated in endosomes and then present them at the T-cell surface, as shown in the figure. Activated T cells could present peptides derived from three structures: the antigenic peptide itself, the class II MHC molecule, or the T-cell receptor. As also indicated in the figure, activated T cells can stably and specifically bind MHC molecules derived from the antigen-presenting cell[14].

This postulated mechanism has several features of interest. First, the target of suppression would only appear on activated T cells undergoing a specific immune response, the only legitimate targets of suppression. Second, this mechanism obeys the known rules of T-cell recognition of antigen, although it postulates a behaviour of class I MHC molecules on T cells that is not yet proved. Third, this mechanism of suppression could be invoked to explain reported examples of suppression that are specific for antigen, MHC or idiotype. Fourth, it suggests a novel explanation for the enigma of the I–J determinant that is so central in studies of suppressor T-cell function[15]. If I–J consists of a peptide derived from a class II MHC molecule bound to a non-polymorphic class I MHC molecule similar to TL or Hmt[16], then the specificity of the determinant would be controlled by class II MHC even though the macromolecular component is not a class II MHC product. An antibody to a peptide–MHC complex has been defined[17], suggesting that this model is possible. Furthermore, the recent structural analysis of I–J by Tada and colleagues is consistent with I–J being a peptide complexed to a class I MHC product[18]. Finally, one may ask whether the paradoxical behaviour of the Ac1–9 peptide analogues could be explained by a similar mechanism. Are the peptides presented by class I MHC to activate suppressor cells that then inhibit the activity of encephalitogenic clones?

The crucial issues for the future are clear. First, can either type of peptide immunotherapy inhibit disease? Second, is there a homogenecity of T-cell receptors in man? Third, will such therapies inhibit essential beneficial immune responses? Fourth, will the MHC genotype of the individual affect the peptide that must be used? These questions must be answered before we can look forward to peptide immunotherapy or immune prophylaxis of autoimmune disease. Will the physicians treating autoimmunity in the future echo Shaw's caricature of Sir Almroth Wright, murmuring "stimulate the suppressors" as they administer their vaccines? Only time and a great deal of work will tell. □

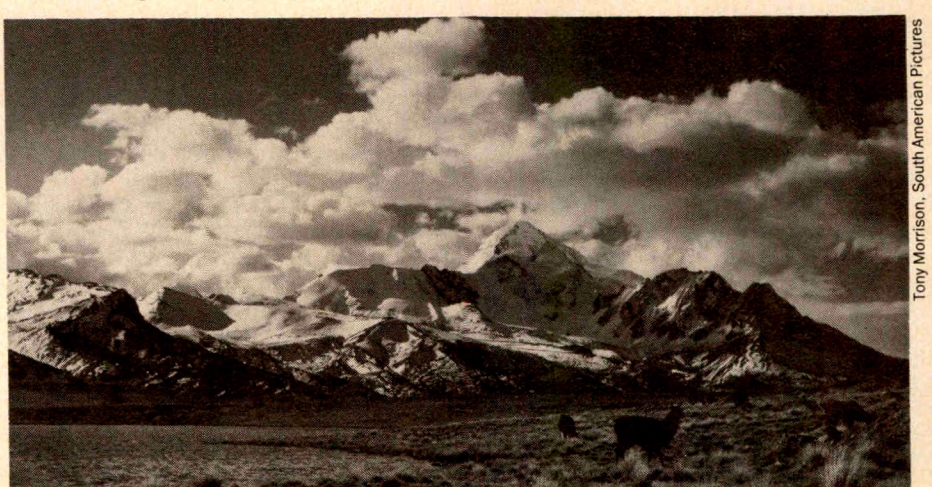
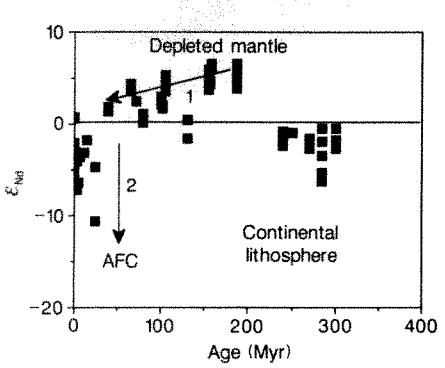
OROGENY



Crustal evolution in the Andes

Marjorie Wilson

SINCE the advent of plate tectonics it has generally been accepted that active continental margins (sites where an oceanic plate is subducted beneath a continent) represent important loci for the growth of new continental crust. For net growth to occur, new magmatic material, derived by partial melting of the Earth's upper mantle, must be added to existing crust in the form of surface volcanics, intra-crustal intrusions or underplated basic material. J.F. Miller and N.B.W. Harris now present in *Geology* (**17**, 615–617; 1989) an interesting synthesis of neodymium isotope data for igneous rocks generated during 300 million years of subduction-related magmatism in the Central Andes in an attempt to distinguish periods of crustal growth from those of crustal reworking. Their approach relies on the assumption that, under certain favourable circumstances, the Nd isotope composition of an igneous rock at the time of its formation (expressed as an initial ratio of $^{143}Nd/^{144}Nd$ or ε_{Nd} value) can fingerprint the source characteristics of the parent magma. Although the approach is neither new nor innovative, the authors provide data fundamental to our understanding of both the rates and mechanisms of crustal growth throughout geological time.



It is now generally accepted that the main source of basaltic magma in all subduction-related tectonic settings (both island arcs and active continental margins) is the wedge of depleted asthenospheric upper mantle overlying the slab of subducted oceanic lithosphere. Once generated, these primary magmas undergo variable and complex processes of fractionation and contamination during their passage through the lithosphere (crust plus mantle) *en route* to the surface. Over the past 300 million years (Myr), the depleted mantle reservoir has been characterized by a rather restricted range of ε_{Nd} values from about +7 to +10 (see graph). In contrast continental crustal rocks have highly variable values (mostly negative, by as much as −30) that become progressively more negative as the age of the crust increases. If these two reservoirs of Nd were the only ones involved in the magma generation process then the interpretation of the isotope characteristics of these central Andean rocks, in terms of distinguishing periods of crustal growth (by addition of mantle-derived magmas) from those of crustal reworking (by partial melting of pre-existing crust), would be comparatively straightforward.

Unfortunately in the active-continental-margin tectonic setting, potential interactions between the primary magmas

Tony Morrison, South American Pictures

Mt Huayna Potosi, Cordillera Real of the central Andes, Bolivia: complex evolution at work.

Neodymium isotope variations (ε_{Nd}) of central Andean igneous rocks as a function of age. Miller and Harris attempt, in their new study, to relate the values of ε_{Nd}, which compares the initial $^{143}Nd/^{144}Nd$ ratio of a sample with that of a chrondritic reservoir (CHUR), to changes in the sources of Andean rocks and so to trace the Andean evolution. (Redrawn from *Geology* **17**, 615–617; 1989).

and enriched subcontinental lithospheric mantle components (which can have ε_{Nd} values overlapping those of crustal rocks) further complicate the issue. This had led to a degree of controversy between the various groups currently studying Andean magmatism, as exemplified in recent articles by G. Rogers and C.J. Hawkesworth (*Earth planet. Sci. Lett.* **91**, 271–285; 1989) and W. Hildreth and S. Moorbath (*Contr. Miner. Petrol.* **98**, 455–459; 1988).

Palaeozoic granitic intrusions (more than 240 Myr old) from the central Andes are characterized by negative ε_{Nd} values (see graph) which Miller and Harris interpret in terms of a crustal reworking event with little net crustal growth. In contrast, at the onset of the main mountain-building phase (orogeny) of the Andes (less than 200 Myr ago), ε_{Nd} values for a wide compositional spectrum of volcanic and plutonic rocks become strongly positive (+4 to +7) suggesting an increasing asthenospheric component to the magmatism, consistent with crustal growth. However, from 180 to 40 Myr ago, ε_{Nd} values decline steadily (trend 1 in the graph) followed by a much more rapid decrease in the past 30 Myr (trend 2), which may suggest increasing degrees of crustal reworking.

Rogers and Hawkesworth, however, prefer a different interpretation for trend 1, involving the progressive mobilization of late Proterozoic mantle lithosphere beneath the arc as magmatism migrated eastwards across northern Chile with time. If correct, this would imply that all samples with ε_{Nd} values from +6 to 0 could represent new magmatic inputs to the crust. Miller and Harris concur with Rogers and Hawkesworth that trend 2 is most easily explained in terms of high-level assimilation and fractional crystallization (AFC) processes, postdating a period of rapid thickening of the crust to 70–80 km caused by crustal shortening. These involve the assimilation of crustal rocks (of contrasting istopic composition) by the rising magmas, which then cool, crystallize and differentiate.

Hildreth and Moorbath present extremely convincing arguments that ε_{Nd} variations, as large as those observed in trend 1, along a segment of the Quaternary (post 1.6 Myr) volcanic front in the southern Andes (33–37° S), can be explained by a model of progressive crustal contamination related to increasing crustal thickness (and possibly crustal age) from south to north. The contamination is envisaged to occur in MASH (melting–assimilation–storage–homogenization) zones at the base of crust. In such zones mantle-derived basaltic magmas mix with acidic partial melts of lower crustal rocks, generating a distinctive base-level isotope signature at each volcano. High-level AFC processes may then further modify the isotopic composition of the ascending magmas to lower ε_{Nd} values. It seems reasonable that a similar model could equally be applicable to the central Andes in which the decreasing base-level ε_{Nd} values along trend 1 reflect increasing crustal contamination in MASH zones, as a consequence of progressive crustal thickening over the past 200 Myr. However, Nd isotope data alone clearly cannot preclude the involvement of enriched lithospheric mantle.

In general, although their article is thought provoking, I feel that Miller and Harris tend to oversimplify the problem of identifying new mantle-derived additions to the continental crust. One important point that seems to have been overlooked is that the strong evidence for an increased crustal Nd component in the younger magmas in no way indicates a declining magmatic input to the system. The crust still grows by the addition of basic magma to lower-crustal MASH zones but this growth is not necessarily reflected in the Nd isotope composition of the erupted magmas. Clearly much more work needs to be done to characterize the geochemical and isotopic variations of Andean magmatism in space and time before we can realistically hope to model crustal growth processes.

ANTIBODY TECHNOLOGY

Will dAbs challenge mAbs?

Penelope Austin

HAVING been unable to profit from the advance that made monoclonal antibody (mAb) production from hybridomas possible[1], the UK Medical Research Council (MRC) has made sure of claiming its rights to a discovery that may make hybridoma technology less important than before. On page 544 of this issue[2], Ward *et al.*, from the same Laboratory of Molecular Biology whence hybridoma technology emerged, describe how bacteria may be employed to produce antigen-specific reagents. The new approach depends in part on the ability to clone a diverse repertoire of rearranged immunoglobulin heavy chain variable (VH) genes, and express them efficiently in bacteria[2,3]. But its success is largely due to the surprising discovery that many VH domains bind antigen with good affinity in the absence of their partner light chain (VL) domains.

Ward *et al.* stumbled upon this unexpected phenomenom while investigating the antigen-binding interactions of the anti-lysozyme antibody D1.3. The crystal structure of D1.3 shows that both heavy and light chains make significant contacts with lysozyme[4]. Although there is some asymmetry, the light chain contributes over 40 per cent of the antigen-binding surface, and few would have predicted that it is not required. In fact, isolated D1.3 VH domains prepared from bacteria bind lysozyme with an affinity only tenfold lower than that of the parent antibody, indicating that the net contribution made by the κ-chain chain to the energetics of binding is small.

With polymerase chain reaction (PCR) primers designed to amplify and clone rearranged VH genes, and an expression vector that directs the secretion of isolated VH domains in *Escherichia coli* already in hand[5], Ward *et al.* were well placed to explore the possibility that D1.3 was not unique in this respect. After demonstrating their ability to use the primers to clone an extensive repertoire of VH genes from the spleen genomic DNA of immunized mice, they made and screened two libraries, one from a mouse immunized with lysozyme, the second from a mouse immunized with keyhole limpet haemocyanin (KLH). VH domains with antigen-binding activity were not hard to find (21 lysozyme-binding and 2 KLH-binding supernatants out of about 2,000 for the lysozyme library; 14 KLH-binding and 2 lysozyme-binding supernatants out of about 2,000 for the KLH library), and for the two lysozyme-specific clones analysed in more detail, the affinity of binding was similar (in the 20 nM range) to that seen for D1.3.

As well as presenting evidence that antigen-specific VH domains are common these experiments lay the foundation of a powerful new technology. Antigen-binding activity can be detected within as little as

days of harvesting the spleen of an immunized animal, and the need for tissue culture is avoided. In principle, the VH domains could be used as building blocks and further selection — for higher-affinity antigen binding — could be imposed after mutation or co-expression with light chain domains.

With the patent application filed away, the MRC is discussing potential applications with a number of companies. For some purposes, such as the rapid clearance of toxins from body tissues, dAbs may have special advantages. For projects, such as the reconstruction of high-affinity antibodies for use in human therapy or the design of catalytic antibodies, dAbs should prove invaluable as building blocks. Whether dAbs will compete with mAbs for more routine procedures, such as the affinity and purification of proteins, will depend on cost. In theory dAbs could be produced more cheaply, but problems of 'stickiness' would need to be engineered out, and production levels raised.

The interest in commercial development shown by the MRC seems a far cry from the days when the National Research Development Council, the only channel through which MRC scientists could then exploit their inventions, wrote of Köhler and Milstein's original monoclonal antibody paper, "It is certainly difficult for us to identify any immediate practical application which could be pursued as a commercial venture". The new advance may even provide an opportunity to gain some ground lost. Greg Winter, senior author of Ward *et al.*, is enthusiastic about the new research and patent opportunities. Ironically, he also sees dAbs as potential "patent busters", able to undermine many of the patented applications of monoclonal antibodies now in force. □

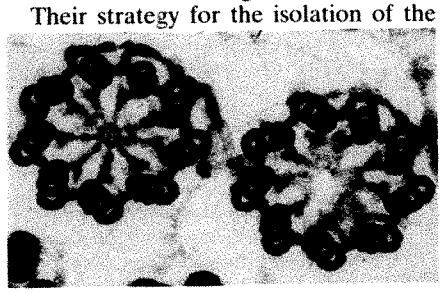
CELL BIOLOGY

Firm base for basal body DNA

Jeremy S. Hyams



BASAL bodies and their *alter ego* the centriole are amongst the most enigmatic cell organelles[1]. They seed the growth of flagella and cilia, they have a complex pinwheel structure (see figure), they can undergo Jeckyll and Hyde-like interconversion at specific points in the cell cycle and, most mysteriously, are able to duplicate themselves in a process that is tightly coupled to, but independent from, the mitotic cycle[2]. The last property has prompted considerable speculation about the existence of basal body/centriole DNA, but a paper from David Luck's group in the latest issue of *Cell*[3] leaves no doubt as to its reality.

Hall *et al.*[3] have studied the biflagellate, unicellular green alga *Chlamydomonas reinhardtii*, a popular model for studies of eukaryotic flagellar function because of the extensive collection of mutants affecting the structure of the axoneme — the flagellar core, which is constructed around nine pairs of doublet microtubules surrounding a pair of single microtubules (the 9+2 axoneme)[4,5]. Although a few of these mutants are sterile (the flagella of *Chlamydomonas* are also used in sexual reproduction), the remainder show classical 2:2 mendelian segregation in a genetic cross and map to one of the 18 nuclear linkage groups in this organism (*Chlamydomonas* also has a well characterized chloroplast genome, mutations in which show non-mendelian segregation).

One class of flagellar mutants, however, violates this basic rule. Called *uni*[6], these strains fail to develop one of the two flagella, with the result that they swim around in circles like a sculler who has lost an oar. The *uni* mutations segregate 2:2 in a cross, but are unlinked to any known chromosomal marker. They do, however, show linkage to a number of other mutants having altered flagellar development, possibly as the result of a defect in some aspect of basal-body function. Analysis of this *uni* linkage group (ULG; also referred to as linkage group XIX[7]) has shown it to be genetically circular[8].

It has long seemed likely that *Chlamydomonas* ULG would be the best for laying to rest some of the age old arguments regarding the ontogeny of the centriole and basal body, and particularly for answering the question of whether they contain DNA. It is with the isolation of the ULG chromosome by Hall *et al.* at Rockefeller University that these expectations have been brought to fruition.

Their strategy for the isolation of the ULG chromosome took advantage of the extensive restriction fragment length polymorphisms (RFLPs) between the DNAs of *C. reinhardtii* and another *Chlamydomonas* species, *C. smithii*. A strain containing the *C. smithii* ULG and all other linkage groups of *C. reinhardtii* was created by crossing the appropriately marked strains. This was then subjected to repeated backcrosses to the *C. reinhardtii* parent. In each generation, markers on the ULG segregated together, whereas markers on the nuclear linkage groups segregated independently. This resulted in a convergence of the *C. reinhardtii* genetic background such that, by the seventh generation, genetic differences between siblings, such as RFLPs, have a high probability of being associated with the ULG.

Pinwheel structure of basal bodies (ref. 11).

By probing digested DNA from all four members of a tetrad from the seventh generation with a cloned genomic fragment containing a repetitive sequence, Luck's group was able to identify a single RFLP that showed the expected 2:2 segregation. This was used to screen a *C. reinhardtii* genomic library in bacteriophage lambda to isolate larger clones containing the putative *uni* DNA, the identity of which was established by correct segregation in the *C. reinhardtii/smithii* lineage.

That these cloned DNAs were indeed associated with basal bodies was dramatically confirmed by *in situ* hybridization. When cells were challenged with the *uni* probes, two bright headlights of fluorescence shone from the bases of the flagella. Hybridization required proteolysis of the cells, suggesting that the target molecule was buried within the structure of the basal body. Treatment with ribonuclease failed to affect the signals, confirming that they were derived from DNA and not RNA.

From its migration in transverse pulse-field gel electrophoresis and its resistance to degradation by γ-irradiation, the *uni* chromosome seems to be a linear molecule of 6–9 megabases. From quantitative hybridization experiments, it appears to be present in two copies per cell. These properties are consistent with the number

of basal bodies in *Chlamydomonas*, but pose problems both for the well established haploid genetics of the *uni* genome and for the circularity of its genetic map. They also present a packaging problem in a cylindrical organelle having internal dimensions of 250 × 500 nm.

Nevertheless, these findings provide the first really convincing evidence for the existence of basal body DNA. The phenotype of the mutations encoded by the ULG strongly suggest that this DNA encodes structural components of the basal body, although clearly not all of them, as the tubulins that form the characteristic ninefold symmetrical structure are specified by nuclear genes[9]. As Hall *et al.* point out, structural complexity, specialized genetics, polyploidy and partial dependence on nuclear genes for structural components are properties that the basal body shares with both mitochondria and chloroplasts. Like them, the basal body is thought to have a symbiotic origin[10]. It will be fascinating to see whether the ULG can be shown to have a homologue in prokaryotes, in mammalian centrosomes or in higher plants, which lack centrioles. The availability of a molecular probe for basal body DNA will not only provide long sought answers to the role of these fascinating structures in the cell, but may also give important clues as to the origin of the eukaryotic condition. □

THERMODYNAMICS

What, if anything, is melting?

R. Bruinsma

MELTING is just about the most familiar of physical changes, so that it might be supposed that it is well understood. Remarkably, this is not so. Indeed, the thermodynamics of the transition continue to surprise. Calculations indicate that the melting of two-dimensional 'solids' is different from that of conventional three-dimensional solids. But a careful study by R. Geer and co-workers (*Phys. Rev. Lett.* **63**, 540–543; 1989) of melting in layers of carefully controlled thickness reveals that the real transition is quite unlike that predicted.

Conventional melting of the solid phase into the fluid phase requires the absorption of a certain amount of latent heat. Transformations between phases of a material during which latent heat is produced are 'first-order' phase transitions. Melting, for many years, was assumed to belong to this class. Fifteen years ago, J. M. Kosterlitz and D. J. Thouless (*J. Phys.* C**6**, 1181–1203; 1973) suggested that matters could be rather different in two dimensions. Two-dimensional melting, they argued, should not involve any latent heat if the melting is triggered by the thermal production of dislocations, a type of structural defect. Subsequently, B. I. Halperin and D. R. Nelson (*Phys. Rev. Lett.* **41**, 121–124; 1978) showed that if this process prevails, then the melting transition is not directly from a fluid into a solid. Instead, a new intermediate phase — the hexatic phase — separates the solid and liquid phases, so that two phase transitions are encountered as the temperature is increased: from the solid to the hexatic and then to the fluid.

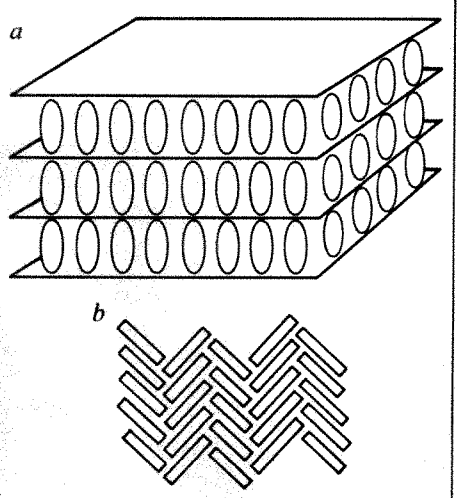

FIG. 1 Smectic liquid crystals: *a*, sideview; b, herringbone pattern (topview).

The hexatic phase should have both liquid-like and solid-like features. As a liquid, the hexatic cannot support shear stress. As a solid there are well defined crystallographic directions — six, in fact (hence its name). This phase turned out to be a elusive quarry. Computer simulations and X-ray diffraction experiments, on rare-gas monolayers absorbed on crystalline substrates, were controversial and inconclusive.

On the other hand, a hexatic phase was discovered, by R. Pindak *et al.* (*Phys. Rev. Lett.* **46**, 1135–1138; 1981), but near certain three-dimensional phase transitions. The materials studied were smectic liquid crystals, which consist of layers of rod-like organic molecules stacked on top of each other (Fig. 1*a*). Inside the layers, the molecules may either move freely as in a liquid (smectic A or Sm A) or they may be positionally ordered as in a crystal (Sm B). On heating, the Sm B phase normally transforms into a Sm A phase — just as for conventional melting. But, over a small temperature interval between the Sm B and Sm A phases, certain smectic liquid crystals, in particular the homologous series *nm* OBC (*n* and *m* are integers), have a third phase, Hex B, which has just the right orientational and positional correlations for a hexatic. The discovery of this phase immediately suggested a way of testing a theory of two-dimensional melting: make films of Hex B and watch what happens to the Sm A–Sm B transition as you lower the film thickness.

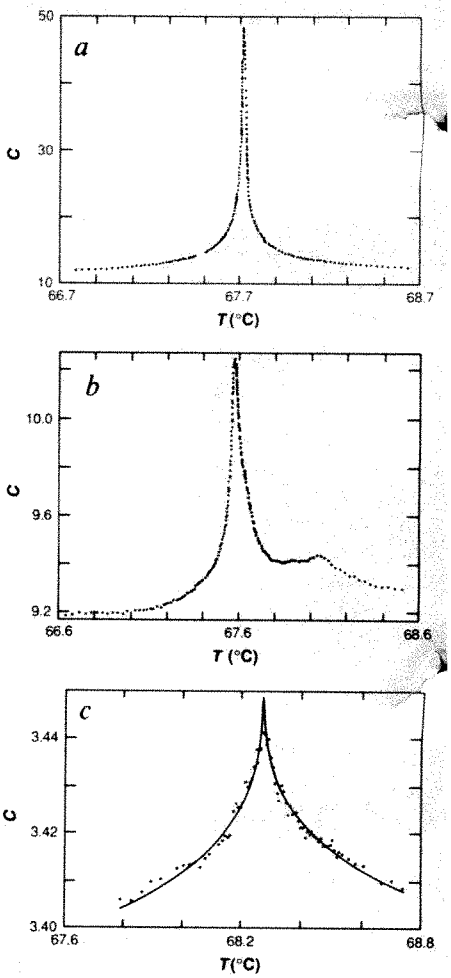

FIG. 2 Specific heat anomalies of 65 OBC liquid crystals (from Geer *et al.*). *a*, With 200 molecular layers, essentially three-dimensional, *C* diverges (goes to infinity) at the critical temperature; $C \propto (T-T_c)^{-\alpha}$, with α positive. *b*, With 10 molecular layers, a surface-ordering transition is apparent close to the bulk melting point. *c*, With just four layers, *C* reaches a maximum finite value at the melting point, and falls away as $C_p \propto -(T-T_c)^{-\alpha}$, with α negative on either side. For a first-order transition, the heat capacity would rise as a straight line (a δ-function) at the melting point, having no slopes on either side. It had been expected that the transition would have an 'essential' singularity, which should show only a broad maximum below T_c.

A possible diagnostic tool to investigate the nature of such phase transitions is the specific heat. For a first-order transition, the specific heat shows a δ-function singularity at the critical temperature T_c — that is, a very narrow peak. For a conventional second-order transition, the specific heat $C(T)$ diverges at the critical temper-

ature as $A/(T-T_c)^{\alpha}$, where A is the critical amplitude and α, the critical exponent. Also, the dislocations of the Kosterlitz–Thouless melting theory behave in a way similar to the 'vortex' defects of a plasmon ferromagnet (the so-called $X-Y$ model). The specific heat of an $X-Y$ model near its Curie (critical) point is known to have an 'essential' singularity at T_c, and the same is expected for the melting transition. In practice, such singularities are unobservable and $C(T)$ should be rather smooth, with a broad maximum somewhat below T_c. By measuring $C(T)$ we thus can tell which of the three cases applies.

But measuring the specific heat of thin films is a demanding occupation. For films with a thickness of the order of monolayers, the specific heat of the sample holder is much greater than that of the film and fantastic precision is required. Nevertheless, Geer *et al.* have now succeeded in measuring $C(T)$ for very thin free-standing films of 65 OBC (Fig. 2). For temperatures near that of the bulk Hex B–Sm A transition, they found a single cusp-like specific heat anomaly — $C(T)$ rises to a finite maximum at T_c and does not diverge to infinity. The critical exponent α is thus, negative; $\alpha \approx -0.26$.

This, obviously, disagrees both with the Kosterlitz–Thouless–Halperin–Nelson theory, which predicts no (measurable) singularity at T_c, and the conventional theory of first-order melting. We must, however, be cautious in drawing conclusions from their results. Real smectics are not just simply layers of ideal two-dimensional fluids of spherical atoms. The molecules carry internal structure. Furthermore, for smectic films, the molecules near the film's surface behave rather differently from those in the interior.

To start with the internal structure problem, the ordered Sm B phase of bulk 65 OBC has an orientationally ordered herringbone-like pattern (smectic E) (Fig. 1*b*). Correlated clusters of molecules with local herringbone order are also clearly visible in the Hex B phase studied by Pindak *et al.*. In fact, it can be argued that the correlations, which assist orientational ordering, are instrumental in stabilizing the Hex B phase in the first place. At any rate, the interaction between the hexatic order and the herringbone fluctuations in bulk hexatics leads to so-called tricritical behaviour in the specific heat with $\alpha = 0.5$ — close to the observed critical behaviour for thick films of 65 OBC (R. Bruinsma & G. Aeppli *Phys. Rev. Lett.* **48**, 1625–1628; 1982). In two dimensions, this tricritical point should vanish (N. Berker, personal communication). This suppression of tricriticality on reducing the film thickness considerably complicates the analysis of the critical behaviour and may account for the vanishing of the divergence in $C(T)$ for thin films. (The authors appear not to account for this.)

Calcium brightens up a brain cell

After microinjecting individual cells in a brain slice with a calcium-sensitive fluorescent dye, David Tank and colleagues at AT&T Bell Laboratories are able to follow the accumulation of calcium in pyramided cells of the guinea-pig hippocampus during synaptic activation. A fluorescent image of a pyramidial cell is shown on the left and a colour-coded map of its calcium content on the right (see page 433).

The second problem is the fact that the role of molecules right at the surface of the film becomes more important as we reduce the film thickness. For thicker films of 65 OBC one observes three phase transitions. Besides the Sm A–Hex B and Hex B–Sm B transitions, there is also a surface-ordering transition. On following these transitions with decreasing film thickness, Geer *et al.* find that for their thinnest films (four layers), the surface ordering transition and the Sm A–Hex B transition coincide. (It is not clear from the paper what happened to the Hex B–Sm B transition.) However, for film thickness greater than four layers, Geer *et al.* can still see the surface-ordering transition (Fig. 2*b*). The associated anomaly is, in fact, comparable in magnitude to the (presumed) Hex B–Sm A anomaly.

Unfortunately, this surface-ordering transition is at a temperature above that for the Hex B–Sm A transition, so it could not possibly be identified with the transition from the solid phase to the hexatic phase, which should be below the Hex B–Sm A transition. Apparently, a completely separate surface phase transition is competing with the interior Sm A–Hex B transition. If the surface layer has Sm B positional order, hexatic order or herringbone orientational order, then this would change the interpretation of $C(T)$. At present, little is known about it. The physics of the molecules at the surface of the film is clearly rather different from those in the film interior, and for thin films we are left with a peculiar mix of surface and interior behaviour.

Despite these questions of interpretation, the demonstration by Geer *et al.* that the specific heats of such extremely thin films can be measured is a notable achievement. It could also be important in other fields where there is an interest in the critical behaviour of very thin layers, such as membranes, adsorbed monolayers or thin superconducting films. □

SENSORY–MOTOR CONTROL

Listening to the voice within

Alan D. Grinnell

LIKE most types of motor behaviour, vocalization depends critically on sensory feedback. Yet almost nothing is known of how or where this sensory–motor integration takes place in mammals. It is very satisfying, therefore, to see the report by Metzner on page 529 of this issue[1], based on extensive single-unit recording from awake, spontaneously-vocalizing mammals, that identifies a site and provides a cellular mechanism for auditory feedback control of one of the most precisely regulated vocalization behaviours known: Doppler-shift compensation in echo-locating bats.

Several species of insectivorous bats use echo-location sounds composed of a 10–100-ms-long constant-frequency component, terminating in a brief, downward frequency sweep. The frequency of the constant component (approximately 78 kHz in the rufous horseshoe bats, *Rhinolophus rouxi*, used in this study) is remarkably accurately regulated, to less than ± 50 Hz, for sounds emitted by a particular bat at rest. Echoes of sounds emitted in flight return Doppler-shifted by up to 4–5 kHz, depending on the relative velocity between the bat and target. Bats use the small frequency and intensity fluctuations in the echo, due for example to insect wing movements, to detect and identify targets[2].

Two remarkable and well-documented adaptations make this possible. First, the auditory nervous system is sharply tuned to a frequency very close to that of the constant frequency at rest, so that small changes in echo frequency cause large changes in response[3,4]. Second, to take advantage of this sharp tuning, the bat lowers the frequency of its next emission just enough to compensate for the upward Doppler-shift in the most recent echo, so that the echo is always held close to the region of maximum auditory sensitivity[5]. This Doppler-shift compensation can be as accurate as ± 50–100 Hz, representing a sensory–motor regulation to within about 0.1 per cent of the constant frequency, over a frequency range of 5 per cent or more. Few, if any, more accurate forms of sensory-feedback regulation exist.

Previous research has yielded clues to where one might look for auditory feedback control of vocalization. The constant-frequency component of the emitted sound is controlled by the degree of contraction of the cricothyroid muscle; this, in turn, is directly correlated with the discharge rate of the superior laryngeal nerve arising in the nucleus ambiguus in the brainstem[6]. Ablation experiments indicate that the behaviour of Doppler-shift compensation can be controlled at the midbrain and tegmental levels[7,8], and there have been reports of attenuation of evoked or single-unit responses in the midbrain and cortical levels during vocalization in bats and primates[9,10].

Most interesting is Schuller's description[11] of four units in the inferior colliculus of *R. ferrum-equinum* that respond differently or respond only to a sound when it is coupled to an electrically elicited vocalization. None of these studies, however, reveals behaviour that helps explain their sensory-feedback control of vocalization.

Alfred Limbrunner

Rhinolophus rouxi — flying blind.

Metzner[1] has now surveyed single-unit behaviour in much of the midbrain and brainstem in freely vocalizing bats. Of greatest interest is a restricted tegmental region rostral and medial to the nuclei of the lateral lemniscus, corresponding to the paralemniscal zone (PLZ) of other mammals. Not only are most PLZ units responsive to acoustic stimuli, but a majority also show firing patterns correlated with vocalizations (but not respiration). Two types of units fire in bursts before each vocalization, with the firing rates inversely correlated either with the duration or the frequency of the constant-frequency component.

Most interesting, however, is a third type, constituting approximately half of the audio–vocal units in the PLZ. These exhibit properties that make them ideal candidates for mediators of Doppler-shift compensation. Their spontaneous activity is strongly inhibited during each vocalization (hence the name VOC-inhibitory units). But when a copy of the emitted sound, reduced in intensity, delayed in time, and shifted in frequency to simulate an echo, is replayed to the bat overlapping its vocalization, all of these units show phasic–tonic responses to the 'echo'. This is remarkable behaviour: the units fail to respond to the bat's outgoing sound and their background activity is inhibited during the vocalization, yet they respond well to a fainter, overlapping, Doppler-shifted echo. The requirements of 'echo' delay and frequency differ for different units, with each showing a maximum response to a given delay and shift in frequency. Significantly, the ranges of delay and frequency shift are precisely those that are effective in eliciting behavioural Doppler-shift compensation.

The pattern of frequency sensitivity of these VOC-inhibitory neurons is particularly important. They respond with exquisite sensitivity to changes in frequency of 100 Hz or less, going from 10 to 100 per cent of maximal response with a change of only about 1.5 kHz, and then maintain maximal firing rates with a further increase of 2–3 kHz. This is quite unlike most other units studied, either auditory or audio–vocal, in that the frequency-response curves fall off steeply on the low-frequency side and relatively slowly on the high-frequency side. This is critical to their postulated role in mediating Doppler-shift compensation.

Horseradish peroxidase injection studies show several indirect connections between the PLZ and the nucleus ambiguus, and a high proportion of PLZ neurons express glutamic acid decarboxylase, suggesting that their neurotransmitter is GABA. Given these connections and the properties of VOC-inhibitory units, it is possible to build a model that can explain Doppler-shift compensation. An echo with a slight upward Doppler-shift excites some of the VOC-inhibitory neurons, which send inhibitory input to the nuclear ambiguus, reducing the firing rate of superior laryngeal motorneurons. With larger Doppler-

shifts, because of the broad high-frequency sensitivity of the units, more of the population fires maximally, increasing the inhibitory input to the motor nucleus and further reducing the constant frequency in the next vocalization. The source of the delay selectivity of VOC-inhibitory neurons is not known, nor is the nature of the excitatory input that can overcome the inhibition during vocalization. Metzner postulates the need for convergence of an excitatory response to the echo with an excitatory input triggered at variable delays by the vocalization.

There are other details to be filled in, of course. But this is a rich story and a significant advance in our understanding of the sensory–motor interactions responsible not only for the regulation of this most remarkable behavioural phenomenon but for audio–vocal control in mammals in general. Bats, with their overwhelming dependence on audition and their use of simple, stereotyped signals, have taught us much of what we know about information processing in the auditory nervous system; they are now doing the same for audio–vocal integration. □

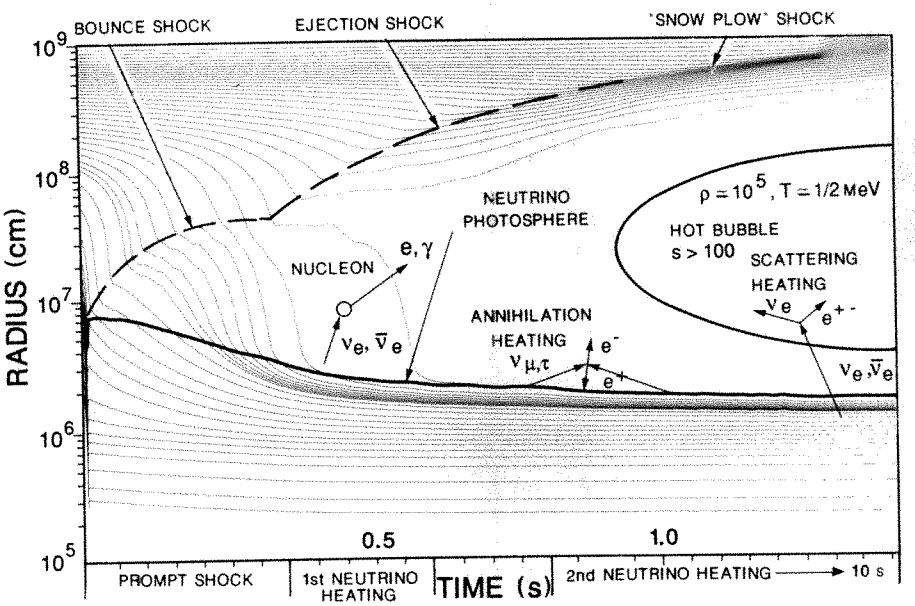
SUPERNOVAE

Hot bubbles drive explosions

Stirling A. Colgate



Our understanding of the initial moments of a supernova was convincingly confirmed by the events following SN1987A: the exhausted core of a main-sequence star collapses under its own weight and emits a massive pulse of neutrinos. Several hours later the explosion of a highly evolved, 12-solar-mass star is observed. The computer modelling of the collapse and emission of the gravitational binding energy of the core in a massive pulse of neutrinos was marvellously confirmed. Similarly, computer modelling of the 'generic' explosion produced, in this case, remarkable agreement with the details of the observed light curve, X-ray, γ-ray and infrared emission in a whole range of details. But the excitement generated by this extraordinary agreement suppressed one leading difficulty: why does the star blow up instead of collapsing to a black hole? New calculations by James Wilson and Ron Mayle[1] (Lawrence–Livermore National Laboratory) presented at a recent meeting* give the first convincing answer to this question.

Our planet and life exist only because of the ejection of high-mass nuclei synthesized in supernovae, which is why the explosion mechanism is of such interest. The gravitational binding energy released in the initial burst of neutrinos that accompanies the collapse (3×10^{53} ergs) exceeds the final kinetic energy of the ejecta (10^{51} ergs = 1 'foe') by a factor of 300. Therefore, in a computational model, one has to couple a mere 0.6 per cent of this binding energy to the ejected matter (half of which is used in overcoming the initial gravitational binding of the ejected matter) to generate an explosion.

This is what we[2] first attempted some 30 years ago at Lawrence–Livermore using computer codes from the nuclear-weapons programme with gravity and neutrino scattering cross-sections added. Subsequent generations of researchers (including many leading astrophysicists) have used models of ever greater complexity, adding refinements and new physics (particularly neutral-current neutrino scattering) to search for a mechanism that convincingly results in an explosion, with 1 foe, rather than a collapse. Wilson and Mayle have finally demonstrated such a model in which a hot, high-entropy bubble produced by neutrino–antineutrino annihilation[3] pushes the ejecta.

Countless calculations teeter at this 0.6-per-cent edge, at which fraction of deposited energy, explosion is divided from collapse. What is worse, calculations claimed successfully to predict explosions have frequently relied on a strong outgoing shock — that is, one travelling at more than the escape velocity. This particular condition has always seemed to me[4] to be unnecessary and insufficient. It is the peculiar phenomenon of a hot bubble in Wilson and Mayle's new model that circumvents this arcane dependence. It is because of the natural formation of a hot, very high entropy bubble surrounding the neutron star that persistantly pushes out the ejecta that I believe this long and difficult problem is solved.

A strong shock wave in matter is the signature that something is pushing with enough force to ensure that the resultant velocity of the matter is greater than its initial sound speed. The shock itself is merely the singularity associated with the inelastic collision that occurs when stationary matter is converted (shocked) to moving matter. Because an inelastic collision always converts the relative kinetic energy to heat, it is evident that the increase in internal energy of shocked matter corresponds to its change in kinetic energy. And because of this internal energy, the flow immediately behind a strong shock is subsonic; that is, a sound wave produced by a perturbation behind a shock will always catch up with the shock. This is fortunate because, if it were not true, a strong shock, once launched, would go on forever because it would not 'know' that its driving pressure had

The sequence of processes occurring in a type II supernova according to Wilson and Mayle. First a star collapses, owing to exhaustion of the fuel and emits electron neutrinos as the compressing matter turns into neutrons. The forming neutron star bounces producing a strong shock that weakens owing both to the thermal decomposition of nuclear matter and the reversal of the neutron star bounce trajectory. Subsequently, a large burst of neutrinos of all flavours heats the infalling matter, starting an explosive shock. Yet later, mu and tau neutrino–antineutrino annihilations in nearly opposed collisions just above the neutrino photosphere generate heat without nucleonic matter, making a hot, high-entropy (100 Boltzmann-unit) bubble, which pushes out the ejected matter in a near 'snow plow', that is, a thin shock. The pressure is maintained because the high-entropy ensures a large scale height adjacent to the neutron star.

* Tenth Santa Cruz Summer Workshop, *Supernovae*, 10–21 July 1989.

disappeared; the Universe would now be filled with strong shocks — an awkward place in which to live. Instead, the driving pressure disappears, and the resulting rarefaction soon reaches the shock, which weakens, which is the failing of previous supernova models.

When the inner regions of a star first collapse, producing a neutron star, there are two mechanisms that give a strong shock in the matter still falling inwards. The first is the elastic bounce of the dynamically forming neutron star, the second is the heat produced by the interaction of a small fraction of the neutrinos that are emitted from the forming neutron star. The energy residing in mechanical motion of the forming neutron star is relatively small, perhaps a few foe, but it is coupled efficiently to the external matter. The neutrino flux carries 100 times more energy, but neutrinos are only weakly coupled to the external matter because of their small scattering cross-section. Hence, many calculations produce a strong shock that barely exceeds (or is sometimes less than) the escape velocity; success or failure is announced accordingly.

The problem is twofold. First, the calculations are terminated after, at best, several seconds because the computer budget is exceeded. Second, the analytic extrapolation neglects the almost certain formation of a rarefaction wave emanating from the cooling neutron star that will reach the shock, reverse the flow and produce a black hole rather than an explosion. Initially, the neutron star formed is so hot that the neutrino flux heats all the matter adjacent to itself and initiates an explosion. But after roughly 10 seconds — the duration of the neutrino pulses measured at the Kamiokande and Cleveland detectors — the neutron star has cooled so that matter next to it is captured and compressed by the extreme gravity; what is more, any of the matter's internal heat, previously causing the pressure that drove the explosive shock, is now itself cooled and thus the matter collapses back onto the neutron star.

The cooling, which arises from electron collisions of the form $e^- + e^+ \rightarrow \nu_e + \nu_e$, occurs in about 200 T^{-5} seconds, where T is the temperature measured in megaelectron volts (MeV). One MeV, equivalent to 10^{10} kelvin, may not seem cool, but close to a neutron star (where the extreme gravity gives a potential energy of 100 MeV per nucleon) it is sufficient to raise normal matter (with a comparable number of nucleons, electrons and photons) to a scale height only 1 per cent of the neutron star's radius. So the push from such matter above 100 scale heights (double the neutron-star radius), where the pressure and density are smaller by e^{-100}, is negligible.

The result of this cooling is that the pressure driving the explosion shock would disappear after about 10 seconds. Without some continuing pressure most of the matter previously shocked out to radii of 10^{10} cm would fall back onto the neutron star. With only a small fraction of this matter, the neutron star would collapse further to produce a black hole. But we find neutron stars in at least half of type-II supernova remnants and the events that followed SN1987A would have been vastly different if a black hole were at its centre.

According to Wilson and Mayle, what circumvents this second collapse is the extraordinary process of neutrino–antineutrino annihilation[3], mostly between mu and tau neutrinos, immediately adjacent to the neutron-star surface roughly half a second after the initial collapse (see figure). Neutrino annihilations produce energetic 20–30-MeV electrons and positrons that are immediately thermalized. The mu and tau neutrinos, having smaller cross-sections for scattering by nucleons, emerge from deeper within the neutron star and so are hotter, $T \approx 10$ MeV, and create a larger flux than electron neutrinos. Head-on collisions are needed, which in turn requires that the density gradient at the neutron star's surface is steep: neutrinos at a steep surface are emitted isotropically, whereas at a shallow surface, they tend to stream radially outwards. The result is heating regardless of nucleon content so that a region of very high entropy is formed.

The entropy is a measure of the ratio of the number of electrons and photons (light particles) to nucleons (heavy particles). If the entropy is high, greater than 100, the corresponding scale height of the atmosphere around the neutron star becomes greater than the star's radius so this atmosphere can push efficiently against the ejected matter and keep the shock going. The hot bubble in Wilson and Mayle's calculation reaches entropies as large as 10^2, so that the pressure is assured provided the bubble does not cool next to the neutron star. This is avoided in the calculation because the temperature required to sustain the pressure is less than that of the cooling neutron star.

This extraordinary process of collapse, bounce, first neutrino push, mu or tau neutrino–antineutrino annihilation, hot bubble formation, and finally explosion would be impossible to believe without the evidence from SN1987A. The model would surely be confirmed if it is shown to be capable of predicting the mixing of ^{58}Ni from the inner atmosphere into the atmosphere as observed at SN1987A. □

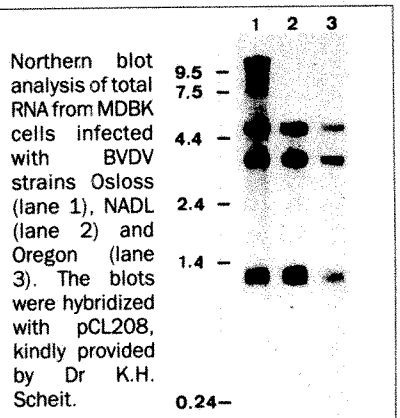
DAEDALUS

Quick reactions

Microwave heating is bringing about a small revolution in chemistry. All sorts of reactions go much faster in a microwave oven than over a traditional burner, and it is hard to believe that the effect is merely thermal. Daedalus points out that many molecules, and most reaction intermediates, have a dipole moment: in the oscillating microwave field, they will spin. If in addition they are even slightly chiral, this spin will drive them along hydrodynamically like little propellers. Even a small directional effect like this should bring reacting molecules together, and drive the products apart, far faster than mere random-walk thermal diffusion. No wonder reaction rates go up.

But, says Daedalus, this effect as it stands is still very inefficient. At any instant, a simple oscillating field will spin a polar molecule clockwise or anticlockwise with equal probability. If it is any sort of propeller, it will shuttle rapidly back and forth along the field-rotation axis; moving much faster than by thermal diffusion, but still in a wasteful one-dimensional random walk. What is needed is a pure rotating field, to spin the molecules one way only. Asymmetric polar molecules would then be powered around a reaction mixture with unprecedented speed and force. DREADCO's circularly polarized microwave oven (available in clockwise or anticlockwise versions) should have a stunning effect on reaction rates, even at settings so low that its pure heating action is quite negligible.

Even more intriguing, it may enhance chiral reactions. Claims have already been made that a reaction mixture spun clockwise produces a different yield of *dextro* and *laevo* enantiomers than one spun anticlockwise; and electrically directed molecular spin should be far more effective than mere bulk angular momentum. Irradiated with circularly polarized microwaves, a chiral reaction should give just one of its possible asymmetric products, with little or no contamination by molecules of opposite handedness.



Biochemistry in particular will benefit. For most of the molecules of life are both polar and chiral; their reactions should be wonderfully enhanced by circularly polarized microwaves. Already DREADCO's biochemists are irradiating bacterial and fungal cultures of all sorts, looking for enhanced growth rates, rapid acceleration of metabolic cycles, improved yields of chirally pure antibiotics, and so on. Conversely, by reversing the sense of the irradiation, the crucial reactions of life could be choked off, or gummed up with useless molecules of the wrong handedness. Daedalus may have invented a new food-irradiation technique, free of the worries invoked by γ-ray treatment. David Jones

Ubiquitin in a togavirus

SIR—Khatchikian *et al.*[1] have shown that insertion of a 28S ribosomal sequence into the haemagglutinin gene of an influenza virus leads to increased viral pathogenicity. We now report the identification in another RNA virus of inserted cellular sequences, which may also be linked to the pathogenesis of a viral disease.

Pestiviruses, currently classified in the family Togaviridae, are positive-stranded RNA viruses that cause severe animal epidemics including bovine viral diarrhoea and hog cholera. Propagation of the bovine viral diarrhoea virus (BVDV) in tissue culture allows one to discriminate between cytopathic (cp-BVDV) and non-cytopathic (noncp-BVDV) strains, both of which can be pathogenic in cattle. One remarkable difference between the two strains is that a non-structural virus-encoded protein (p120) of unknown function is processed to a small product of M_r about 80,000 only in cp-BVDV-infected cells. Interestingly, the coexistence of both biotypes in persistently infected animals is linked to pathogenesis of fatal mucosal disease[2].

On comparing the genomic sequences of two cp-BVDV strains Osloss[3] and NADL[4] and one hog cholera virus strain[5] we found insertions in the BVDV gene

Northern blot analysis of total RNA from MDBK cells infected with BVDV strains Osloss (lane 1), NADL (lane 2) and Oregon (lane 3). The blots were hybridized with pCL208, kindly provided by Dr K.H. Scheit.

coding for p120, which may affect its processing. The Osloss insertion comprises 228 nucleotides, the NADL insertion 270 nucleotides. The two inserted sequences are not similar in either nucleotide or deduced amino-acid sequence. Whereas the NADL insertion is not similar to any sequence in the current data bank, the amino-acid sequence deduced from the Osloss insertion is almost identical to animal ubiquitin: compared to the ubiquitin sequence conserved in all animals[6], only 2 of the 76 amino acids differ.

To examine whether the ubiquitin coding sequence is specific for the Osloss strain, a *Bgl*II fragment derived from a porcine polyubiquitin complementary DNA clone (pCL208, ref. 7) was hybridized to total RNA of cells infected with different strains of cp-BVDV. The ubiquitin probe recognized genomic RNA from the Osloss strain only (see figure; the other three bands visible in all lanes obviously represent bovine ubiquitin messenger RNAs).

Based on these observations, we would like to suggest a novel model for the pathogenesis of mucosal disease. In persistently infected animals a noncp-BVDV mutates to a cp-BVDV biotype by taking up cellular sequences during a recombination event. This would explain the isolation of serologically closely related noncp-BVDV and cp-BVDV from one animal suffering from the disease[8,9]. Once this recombination has occurred, horizontal transmission of the resulting cp-BVDV strain follows. Further efforts will be directed towards a comparison of cp-BVDV and noncp-BVDV strains, including the detailed investigation of their p120 and its processing.

Particle migration on cells

SIR—In their recent article entitled 'Nanometre-level analysis demonstrates that lipid flow does not drive membrane glycoprotein movements'[1], Sheetz and colleagues claim to have eliminated the membrane flow hypothesis of cell locomotion[2]. Their conclusion arises from experiments in which they add 40-nm gold particles coated with concanavalin A (Con A) to migrating macrophages. Using an ingenious optical technique involving image processing, they follow the movements of individual gold particles on the dorsal surfaces of these cells. They observe that the particles alternate between two modes of behaviour: either they diffuse by brownian motion, or they move (more or less directly) away from the leading edge of the cell. As analysis of particles in the diffusive mode shows that there is no superimposed directional drift on a particle, they believe that there can be no bulk (lipid) flow in the cells' plasma membranes. They suggest that the alternative mode — direct motion away from the leading edge — is driven by the actin cytoskeleton.

There appears, however, to be a conceptual error in the article. In measuring the diffusion of particles on the dorsal surface (finding there is no superimposed drift), the authors use a stationary marker on the glass slide as a reference point (see legend to Fig. 2 in ref. 1). But if the cells are actually moving (which is assumed, but not shown), then any particle on their dorsal surface that is stationary with respect to the substratum must be moving rearwards with respect to the cell. In other words, the particles, even when in a diffusive mode, must be moving away from the cell's leading edge. This is what is expected on the membrane flow scheme (see ref. 3, where this point has been discussed): the observations of Sheetz *et al.* could therefore be used to argue that membrane flow does exist in these cells.

There is an additional problem in the interpretation of the observations. Sheetz *et al.* assume the particles are on the cells' dorsal surfaces, but do not establish this. They could be inside the cells, or between the cells and substrate (under the cells). The reason for this is that the thickness of the leading lamella of a cell is usually about 250 nm (for example, ref. 4 shows the lamella varies in thickness between about 150 nm to 700 nm in one fibroblast), and the depth of focus of the microscope used is 250 nm (M. Sheetz, personal communication). It seems likely that some of the particles observed are inside the cells because macrophages are very active in endocytosis and phagocytosis. Con A actually stimulates membrane internalization in these cells[5], about half the surface-bound Con A being internalized in a few minutes[6]. Alternatively, it is conceivable that the particles are semi-trapped under the cells. In either case, if the particles are not on the dorsal surface, conclusions derived from the assumption that they are, would not be valid.

Finally, Sheetz *et al.* resurrect one of the old arguments against membrane flow: the intracellular vesicles that, on the membrane flow scheme, are supposed to move forward inside the cell and exocytose at the cell's leading edge have

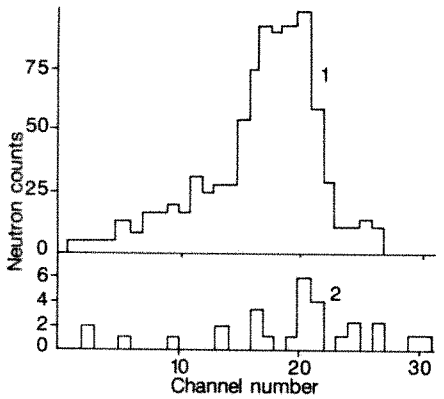
not been 'seen', although there is no obvious reason why they should be visible with current techniques. In an accompanying letter[7], Sheetz and colleagues report that their Con A labelled particles "on" fish keratocytes sometimes move long distances forward at great speed. Could it be that they have discovered just those *intracellular* vesicles they claim do not exist?



In the light of all this, the accompanying and enthusiastic obituary of the "lipid-flow model" in *New and Views*[8] seems premature.

Titanium fracture yields neutrons?

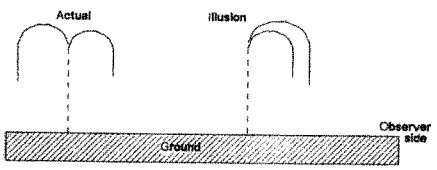
SIR—In recent experiments[1,2], we showed that violent mechanical action on heavy ice and lithium deuteride lead to neutron emission at levels substantially above the background, indicating the occurrence of d–d nuclear reactions. Because of current interest in the possibility of d–d reactions as a result of saturating titanium and palladium with deuterium[3,4], we felt that a test of mechanical agitation of titanium in the presence of deuterium was warranted.

Titanium chips of technical purity were tested in conjunction with heavy water, deuterated polypropilenium (PP) and lithium deuteride. Ti chips were put in a vibromill, operated at 50 Hz and with an amplitude of 5 mm (the power applied was ~ 10 Wg^{-1}). Two-thirds of the volume of the vibromill drum was filled with steel balls 6 mm in diameter[5,6], the remaining one-third comprising Ti chips and deuterated material. In control experiments, finely crushed Ti chips were used separately, as well as D_2O and PP(D_6).

Histogram of neutron counts *versus* analyser channel for a calibrated neutron source (curve 1) and for Ti chips agitated with 10% D_2O and 4% PP(D_6) (curve 2).

Our neutron detector was a block of seven proportional counters, immersed in a tank of oil and covered with cadmium sheet, placed 15 cm from the vibromill drum. Detector counts were brought out to an AI-256-6 analyser. Detector efficiency was measured using a source of 200 neutrons s^{-1} intensity placed in the vibromill drum (curve 1 in the figure), and at regular intervals the neutron background was measured by removing the operating drum to a large distance.

In our experiments, neither Ti chips nor deuterium containing compounds showed a neutron signal above background (0.05 counts s^{-1}) when put separately in the drum, but when Ti chips were combined with 10% heavy water or 4–5% PP(D_6), or with both, a neutron flux 6–7 times background (0.31 ± 0.13 counts s^{-1}, taking detector efficiency into account) was measured, as indicated in curve 2 in the figure, which shows the results from Ti + 10% D_2O + 4 % PP(D_6). A constant excess over background was measured for 10 minutes, with a subsequent attenuation after crushing of the chips was stopped. The greatest effect (0.41 ± 0.14 counts s^{-1}) was measured using 10% D_2O and 4% PP(D_6) when the vibromill drum was cooled in liquid nitrogen after mechanical action was stopped. After three or four cycles of vibration, each lasting 3 minutes, neutron emission fell to the background level. Smaller effects (0.14 ± 0.02 counts s^{-1}) were found using LiD with PP(D_6).



We conclude that d–d reactions occur when Ti particles in the drum are saturated with deuterium, perhaps as a result of deuterium diffusion through freshly created Ti surfaces produced by the fracturing[6]. At least 2 atoms of D per atom of Ti can be absorbed, and the lattice of Ti particles deforms by as much as 25% during this absorption[7]. So it is conceivable that absorbed deuterons can approach each other closely enough for fusion to occur. In addition, electric fields of up to 10^7 V cm^{-1} can be created by destruction of the crystal lattice, perhaps making d–d reactions more probable[8]. The increase of neutron counts with cooling in liquid nitrogen may indicate increased absorption of D, as it is known that cooling decreases the partial pressure of absorbed hydrogen or deuterium[7].

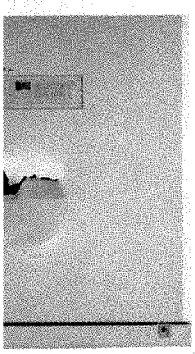
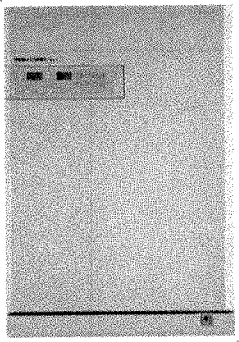
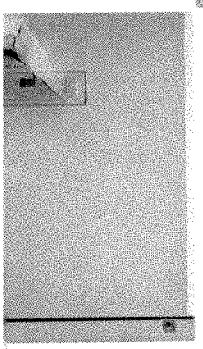
Pyrotechnic illusion



SIR—While watching a recent display of fireworks, I observed a robust illusion of motion. Clearly, when a flare shot into the sky bursts, and its payload of self-luminescent fragments scatters, there must be a uniform distribution of horizontal directions of fragment trajectories, with respect to the vertical axis formed by the initial shot. However, all fragments appear to come towards the observer, or at least into the hemisphere formed around the observer and centred on the flare's explosion point. Even when one is consciously aware of the illusion, it seems impossible to decide which fragments are really going away. Apparently trajectories going away are so similar to trajectories coming towards the observer that the brain interprets all motion parsimoniously as movement towards the observer. It is important that the background is black, with respect to the bright, moving fragments; fireworks seen against clouds or against textured stadium backgrounds can be analysed for towards/away fragment motion. Even when viewed through the limited field of binoculars, the initial burst of fragments retains the illusion of motion only towards the observer.



Of course, after a second or so all horizontal motion of the fragments ceases and only earthward motion is seen. However, there are special fireworks with fragments which change direction after the initial burst, and some of these fragments can be seen going momentarily away from the observer. Pyrotechnics seen on television show the same illusion, but less dramatically than those seen in person.



I have found no mention of this phenomenon in books. Colleagues have suggested various explanations, my favourite being the notion that the initial burst is rapidly enlarging and and an enlarging object is interpreted as coming towards the observer (S. Ullman, personal communication). I wonder if other readers of *Nature* can offer more insights.

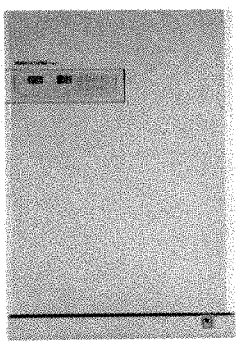
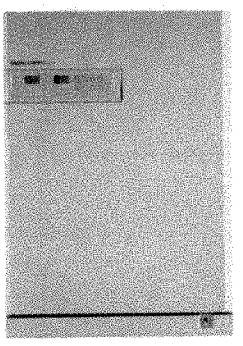
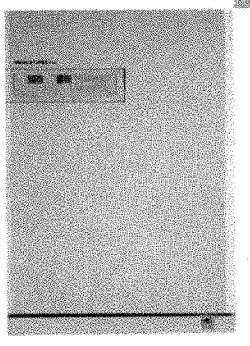
The reason for ESPEC's success is no secret ——by constantly reappraising our products, we answer your needs.
And our new line of CO_2 Incubators does just that. Concerned about temperature stability? Our water-jacket system maintains uniform temperature distribution.
Troubled by contamination? We've minimized the risk with a low-velocity blower circulation system that ensures high-speed recovery of temperature, humidity, and CO_2 concentration after door opening.
Is ease-of-use a concern? We've positioned the operation panel and control unit near the top of the door, so operation and maintenance procedures can be performed from the front of the cabinet.
Short on space? Despite a sizeable 167-litre capacity, our new Incubator is 20 percent smaller.
Call us today for more information. We think you'll be pleasantly suprised.







THE NEXT STEP IN THE EVOLUTION OF THE CO_2 INCUBATOR FROM ESPEC—THE LEADER, BY NATURAL SELECTION.

ITY IS MORE THAN A WORD

BioChemika

Close to an Encyclopaedia- The Fluka BioChemika Handbook

Fluka BioChemika is rapidly becoming a new synonym for clearly specified, high quality biochemicals and reagents for use in the broad field of life sciences.

Fluka's aim for better service has led us to expand our testing of the quality of the BioChemika range. Therefore, we have progressively supplemented the standard chemical analyses with the newest biochemical investigation methods. Today, we assay every product according to its biological application. This gives you the assurance of consistent high quality.

The Fluka BioChemika Handbook is an additional element of the Fluka Service. This book contains detailed scientific, technical and practical information, literature references and an accurate description of all Fluka BioChemika products. Ask for your free copy!

Please visit us at the Biotechnica in Hannover 17.–19.10.1989

PRECISE CONTROL OF REACTIONS

FULLY PROGRAMMABLE DRI-BLOCK® TEMPERATURE CYCLER PHC-2

This latest programmable Dri-Block® temperature cycler PHC-2 has a powerful microprocessor programming capability yet is designed for simplicity of operation. It is now possible to link programmes, hold temperatures for long periods choose four ramp rates up and down and recall temperatures and times from the PHC-2 memory. Two models are available for use with either 0.5 ml or 1.5 ml microcentrifuge tubes.

- Temperature range 0°C–99°C
- Fast temperature change
- Wide and variable number of segments, programmes and cycles – limited only by memory capacity.
- Four user selectable up/down ramp rates
- 99 hour maximum hold time
- Remote sensor in dummy tube to read sample temperature and initiate programme timing.
- Block uniformity 3°C
- RS232 outlet/centronics printer output
- 54×0.5 ml or 24×1.5 ml microcentrifuge tubes
- Water cooled with separate connection for end of programme below ambient cooling
- Temperatures and times held in memory for recall to screen or printer

PHC–1

For less sophisticated programming requirements the alternative model PHC-1 is a simple to use heat/cool unit providing a repeatable cycle of up to three independent temperatures and dwell times. A standard aluminium block will accept up to 54×0.5 ml capped microcentrifuge tubes.

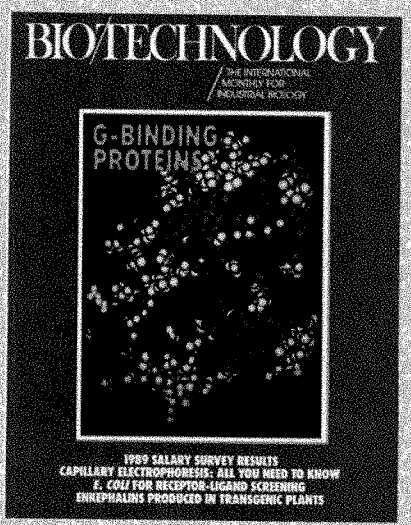
FOR COVERAGE OF TODAY'S BIOTECHNOLOGY



INDUSTRY TURN TO THE SPECIALIST

BIO/TECHNOLOGY

Each month, BIO/TECHNOLOGY offers its readers more news, features, evaluations and up-to-the minute information than any other biotechnology publication.

TRULY INTERNATIONAL PERSPECTIVE

Bio/Technology's scientific correspondents report from around the world on vital details of commercial and scientific strategies, government regulations, funding issues, new laboratories, scale up, financial news, patents and new biological materials. This essential information helps you monitor competition and developments worldwide, allowing you to make informed decisions within your work.

COVERAGE OF ALL BIOTECHNOLOGY RELATED DISCIPLINES

From soil improving bacteria to animal husbandry and from transgenic mouse milk to fermentation, Bio/Technology covers all biotechnology related disciplines. The magazine's in-depth editorial deals with basic research techniques right up to large scale production.

THE VERY BEST ORIGINAL BIOTECHNOLOGY RESEARCH

Bio/Technology is the only international journal to publish original research specifically about biotechnology. Each paper is carefully refereed, ensuring that the research you see is of far-reaching importance.

ORDER YOUR SUBSCRIPTION TODAY

For the annual subscription rate of just £70.00 we will send you 12 monthly issues packed with information. Simply complete the order form below.

EMBL

SEQUENCE DATABASES ON CD-ROM

The EMBL Data Library has begun distribution of its sequence databases on CD-ROM, a robust, reliable, high capacity medium suitable for distribution of large databases.

The EMBL CD-ROM includes:

Nucleotide Sequences: The EMBL Nucleotide Sequence Database (now over 26,000 entries) sequence, documentation and index files in the EMBL distribution format.

Protein Sequences: The SWISS-PROT Protein Sequence Database (now over 10,000 entries) sequence , documentation and index files in the EMBL distribution format.

NBRF/PIR Format: The two sequence databases for use on VAX/VMS computers with homology search software such as FASTA.

Retrieval Software: Software for query and retrieval of data from the sequence databases by: entry name, accession number, citation, author names, organism name, feature key, database cross-reference, free text, creation date (in all combinations). Results can be viewed, printed or copied to user disk. Requires: • MS-DOS PC • 640 Kbytes memory • 1 floppy disk drive • Preferably a hard disk • CD-ROM drive • interface card with MS-DOS CD-ROM extensions capable of reading ISO-formatted CD-ROMs • CGA, EGA or HERCULES graphics adaptors.

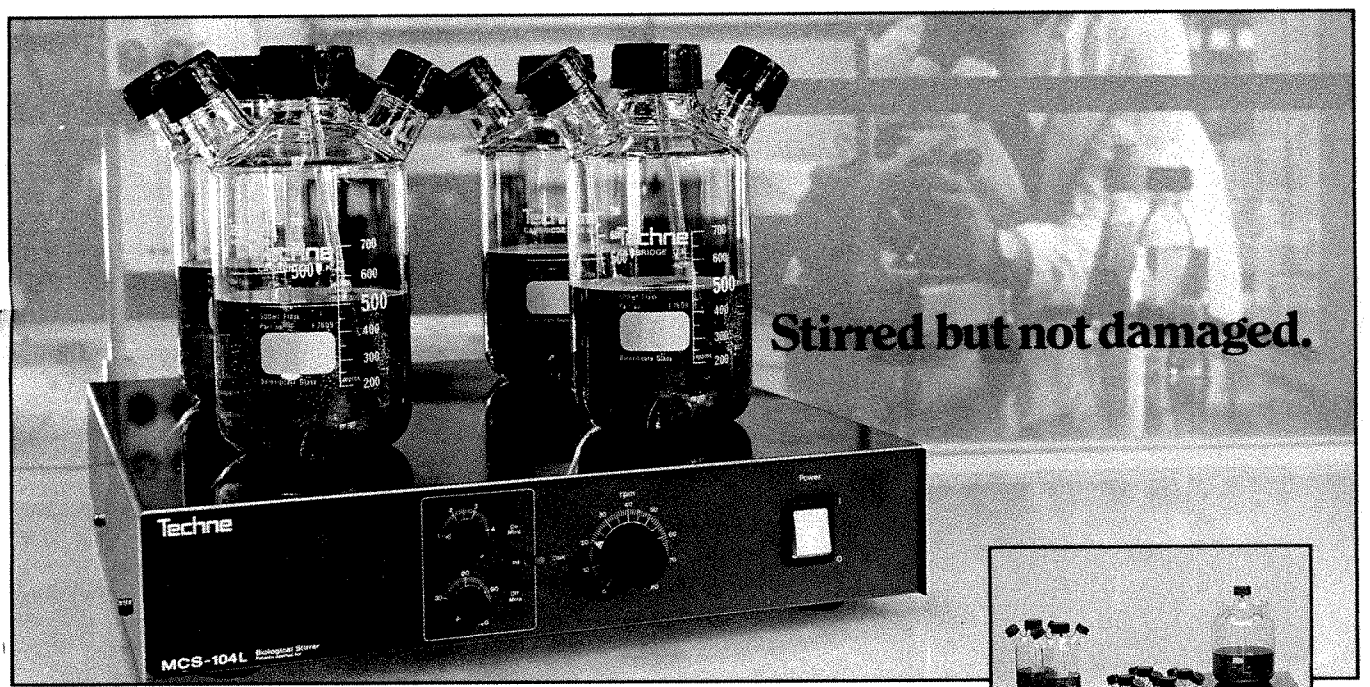
Availability:

The EMBL CD-ROM is distributed quarterly. It conforms to the ISO standard 9660.

Prices:

Academic rate (per CD-ROM) DM 200
(50% reduction for EMBL and EC member countries)

Commercial rate DM 500



Free prototype CD-ROMs are available while stocks last.

Reader Service No.4

Techne biological stirrers provide a controlled stirring for delicate mammalian and plant cells. The gentle movement causes a spiralling mixing which ordinary spinner flasks find hard to achieve. Growing conditions have therefore proven to be ideal for cells grown in suspension or on microcarrier beads and for production of monoclonal antibodies. Important features include:

- Unique SOFTSTART stirring action to prevent cell damage.
- Calibrated speed control and interval stirring.
- Virtually heatless operation for incubator use.
- Special patented vessel and stirrer rod ensures good Thompson flow with vertical and horizontal circulation.
- Vessels contain no bearings or mechanical parts and the borisolicate siliconised glassware is easily autoclavable.
- Six culture vessel sizes from 125ml to 5000ml.
- Maximum size unit now takes four 5 litre vessels.

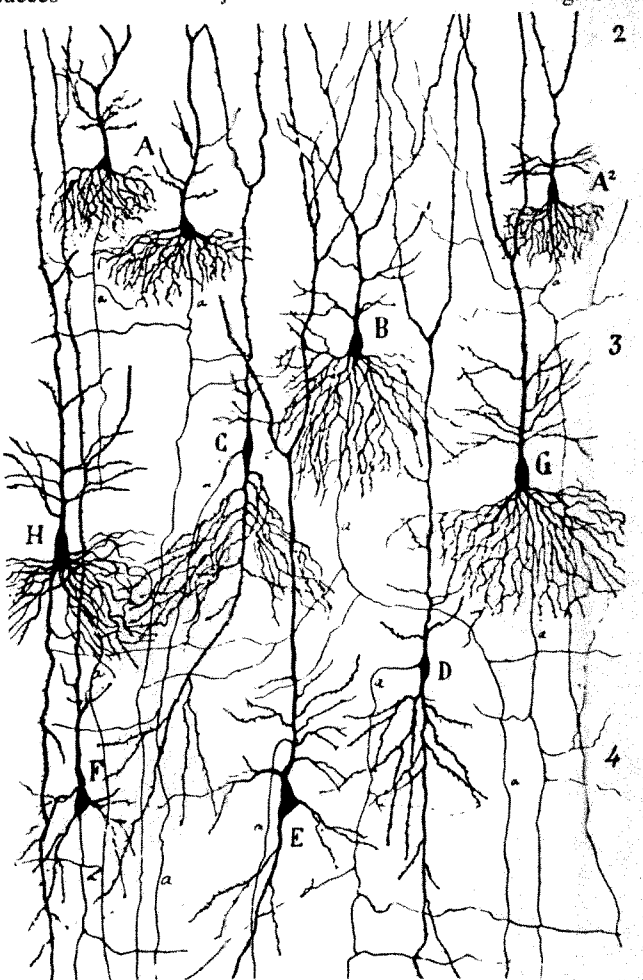
The neuroanatomist



Sanford L. Palay

Cajal on the Cerebral Cortex: An Annotated Translation of the Complete Writings. Edited by Javier DeFelipe and Edward G. Jones. *Oxford University Press: 1989. Pp. 654. £50, $65.*

THE last quarter of the nineteenth century was marked by a steady increase in knowledge about the nervous system. Advances in neuroanatomy, neurophysiology, psychology, psychiatry, clinical neurology and pharmacology arrived in rapid succession, so that by the beginning of the twentieth century a remarkable body of knowledge had accumulated. Here was a storehouse of questions and problems that are only now giving up their answers to new and more powerful techniques.

Naturally, progress on all fronts was not even, and during the last decade of the century neuroanatomy advanced more rapidly and more consistently than any of the other disciplines. That phenomenal growth was due almost entirely to the work of one man, Santiago Ramón y Cajal, who from 1888 to 1911 almost single-handedly created modern neuroanatomy. The centenary of Cajal's birth in 1952 passed virtually unnoticed, but the 130th anniversary was marked by the publication of a splendid book of photographs of Cajal's life and a text in Spanish by P.L. Entralgo and A. Albarracin. The fiftieth anniversary of his death in 1984 provided an opportunity for commemorating the life of this remarkable scientist and opened a spate of celebrations of his creative activity. A symposium was held at that time in Valencia. Last year a symposium was held in Barcelona to honour the centennial of his first publication, in 1888, on the structure of the nervous system, his analysis of the architecture and development of the cerebellar cortex. A few months later the book reviewed here was published by Oxford University Press. Just recently, MIT Press has reissued Craigie's English translation of Cajal's autobiography, which had been out of print for almost two decades. These centennial anniversaries prompt a return to the original texts in order to re-evaluate their contribution to modern neuroscience.

Cajal on the Cerebral Cortex consists of English translations, set in chronological order, of all Cajal's works on the structure and organization of the cerebral cortex. The text is divided into four periods — early, middle, consolidation and final — and each section is introduced by a summary that places the text in its time both in Cajal's life and *oeuvre* and in the science of the period.

Layer of the tasselled pyramids — a drawing by Cajal of the olfactory sphenoidal cortex from a one-month-old child. (Taken from *Cajal on the Cerebral Cortex: An Annotated Translation of the Complete Writings.*)

The book is rounded off by an interesting chapter of more than 60 pages describing and analysing Cajal's materials, his methods of work and drawing, as well as the importance of his specific contributions to cortical histology. DeFelipe and Jones examined Cajal's own preparations preserved in the archives of the Cajal Institute in Madrid, and even found the same cells that he drew, so that they could photograph them. This chapter compares Cajal's work with modern investigations. It shows how prescient he really was and how closely modern neurohistology has followed and corroborated his diagrams and interpretations (which is not to say that he did not make any mistakes or that nothing new has been added to his work). This chapter is a small jewel, expertly assimilating the details of Cajal's voluminous study of the cortex into the most recent morphological, cytochemical and connectional investigations.

The translators have chosen to follow the language of the original texts as closely as possible in order to render into English "the cadences and . . . color of Cajal's prose". Unlike certain earlier translators, they do not paraphrase his thoughts, but give an equivalent expression in English as far as possible. They have had to do more than translate individual words and phrases, however, for they have had to modernize many terms in order to make them comprehensible to a present-day audience. Nevertheless, they could not resist the temptation to translate Cajal's *etranglements* into *strangulations*, no doubt picturesque, but hardly comprehensible to the neuroscience graduate-student who has never seen a live node of Ranvier. Despite a few rough passages, the text is generally in graceful English and does credit to Cajal's style as well as to the scientific content.

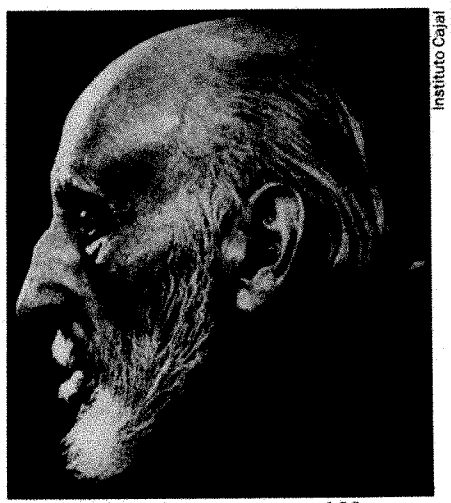
The translation itself begins with Cajal's first paper on the texture of the cerebral gyri of the lower mammals from the *Gaceta Medica Catalana* of December 1890, and it reaches a climax with the great chapters on the cortex in the *Histologie du Système Nerveux*. In the first paper, Cajal describes the cells of the molecular layer of the cortex and the nerve fibres in this layer that originate from the cells of Martinotti in underlying layers. This is a topic to which Cajal often returned, correcting his early mistakes and enlarging his description. In fact, the succeeding papers, lectures and book chapters give the student a chance to follow the development of an astute, careful and absolutely honest observer as he increases his skills, learns from his mistakes, enlarges his understanding. This is a rare opportunity. There are few scientists whose intellectual development can be so carefully followed and whose development can be traced so rewardingly. For Cajal was always looking for the principles in the detail. He tried to describe and draw what he saw as exactly as possible; but he never lost sight of his aim, which was to understand how the nervous system was constructed so that its function could be discerned. ▶

The translators have performed a signal service in scholarship by comparing the Spanish and French and, where necessary, the German versions of the same texts that were published in Cajal's lifetime. Footnotes at the end of each paper explain where the texts differ, where Cajal added something in one language that was not present in the original, or corrected a mistake in the original by further research before the non-Spanish version was published. These inklings into the mind of the master make the footnotes as interesting as the texts.

The translators have also re-created almost all of Cajal's references. Although they say that they had "little difficulty in identifying the vast majority of the works to which he referred", it could not have been an easy task to reconstruct full titles and journal references from Cajal's often sketchy citations. These are given not only at the end of each translated paper, but also in alphabetical order as a bibliography at the end of the volume. A useful index completes the book.

During his early career, Cajal felt isolated because his contemporary scientists did not read Spanish and ignored him. But even in those days, the best scientists knew several European languages and travelled widely. Koelliker carried on a long correspondence in Italian with Golgi, and he learned Spanish in order to read Cajal's works in the original. Besides, there was a strong interest in translating important works into the most active scientific languages. Golgi was translated into German and French, and so was Cajal. But in the late twentieth century all scientists are expected to understand English, and the classic works that everyone in earlier times knew and could read in the original now go unread and unknown by most neuroscientists, simply because they find it too much trouble to read another language. Few of our contemporaries have read his work, and for these the principal source is his great book, the *Histologie du Système Nerveux de l'Homme et des Vertébrés*, translated into French from the Spanish and much enlarged.

Parts of Cajal's works had been translated into English before (those on the retina, the hippocampus, the regeneration of nerves, the embryology of the nervous system and the neuron theory). The present volume adds an extremely valuable set of papers to these earlier translations. It makes them available to a new generation of neuroscientists, who can find their roots in the work of genius of a century ago. □



Sanford L. Palay, 78 Temple Road, Concord, Massachusetts 01742, USA, is editor-in-chief of The Journal of Comparative Neurology.

Cajal by himself

Santiago Ramón y Cajal's autobiography *Recuerdos de Mi Vida* was published in instalments between 1901 and 1917, the period when he reaped his rewards for 20 years of passionate devotion to describing the structure of nervous systems. The English translation by E. Horne Craigie, *Recollections of My Life*, appeared in 1937. As Sanford Palay points out above, it has recently been reissued in paperback by MIT Press with a new foreword by W. Maxwell Cowan. This is a delightful account of the development and flowering of one of the most creative individuals in modern biology.

The son of a poor country doctor in the hill country of north-east Spain, Cajal was a rebellious, ingenious child with considerable artistic and musical talents but little love of book learning. He scraped through medical training and it was only after a serious illness, contracted on military service in Cuba, and an early marriage, that his imagination was captured by descriptive and microscopic anatomy. Poverty deterred him from the then-fashionable pursuit of microbiology, and an encounter with Camillo Golgi's new method for staining nerve cells convinced him that his life's work lay in studying the nervous system.

By his own account an obsessive, Cajal also had a breadth of interests from politics to chess and photography. The last of them contributed significantly to his career as a neuroanatomist: his experience with manufacturing gelatine–bromide plates introduced him to the chemistry of silver salts, the basis of many stains for nerve cells, including Golgi's. He also invented a photolithographical technique for reproducing his splendid drawings of neurons.

Instituto Cajal

Cajal in 1934 at the age of 82.

Working in an isolated academic community, Cajal had to struggle for international recognition. He taught himself German and translated his own papers into French. Against this background, his achievement in establishing so many concepts fundamental to modern neuroscience is all the more extraordinary.

Immunological ideas

N.A. Mitchison

The Immune System. By Rodney E. Langman. *Academic: 1989. Pp. 209. Hbk £31.50, $49.95; pbk £14.50, $22.95.*

In 1968 Peter Bretscher and Melvin Cohn, one of the masters of modern immunology, formulated the associative-recognition or two-signal theory for self–non-self discrimination: a lymphocyte requires two signals in order to undergo productive activation, whereas a single signal results in the clonal deletion that underlies tolerance-of-self. Since then Cohn has collaborated with Rodney Langman, and this book, written by Langman but with a 33-page introductory essay by Cohn, gives a clear and punchy account of the ideas that have sprung from the theory.

Langman deals with the origin in evolution of tolerance, of B and T cells, of the major histocompatibility complex (MHC), and indeed of the whole immune system, and touches on interleukins, complement and other effector functions, and on the biochemistry of lymphocyte activation. The main themes, in addition to associative recognition, are the dual-recognition–single-receptor theory of recognition by T cells; the protecton theory of establishing the antibody repertoire in two stages, by germ-line diversification followed by somatic mutation; and the adaptor theory of determining effector class (cytotoxic T-cells versus antibody) by suppressive regulation.

The book is not offered as a logical or comprehensive exposition of how the immune system works (for that I recommend my colleague Martin Raff's chapter in *Molecular Biology of the Cell* by Alberts *et al.*). Nor is it in any sense a review — the contributions of others are hardly acknowledged, there is no narrative to tell us what prompted Langman and Cohn to form their views, and no attempt is made to sort out the key observations. As such *The Immune System* will bemuse beginners and irritate the more experienced immunologist. On the other hand, for someone who already has a grasp of the subject, it is fun to watch the tide of immunological observations being accommodated within such a strong conceptual framework.

I find that framework weak at the following points. The account of evolution traces the immune system back to the defence system of invertebrates, rather than to their homotypic adhesion molecules, and the view of vertebrate evolution starts from terrestrialism but nevertheless admits the existence of sharks. The discussion of evolutionary waste omits the

highest cost of evolution, namely the maintenance of polymorphism. The contention that antigen processing and presentation by MHC molecules can be dispensed with in recognition by T cells is doubtful (the implications of the Bjorkman–Wiley structure do not seem to have reached La Jolla). There is a failure to realize how different modes of loading underlie the difference between MHC Class I and Class II molecules and to comprehend the importance of suppression for the control of hypersensitivity. The new ideas about staging in the thymus (the CD4/CD8 double-positive cell as the target of selection) are neglected. Finally, and most seriously, a key idea not mentioned in the book is that by relegating to T cells the job of maintaining self-tolerance, B cells become free to hypermutate.

On the positive side, Cohn and his colleagues were the first to realize the importance of the signals that lymphocytes receive through molecules other than their antigen-binding receptors. Just how important those signals are is evident in recent experiments demonstrating that cloned T-cells become unresponsive if stimulated in their absence. The fact that this book continues to present them in a much over-simplifed fashion as a single second signal hardly detracts from the credit. Cohn also got the balance between germ-line and somatic diversification right at an early stage, and the expanded account presented here of the logic of diversification makes interesting reading. But I wonder whether the effort is justified: perhaps it makes more sense to sit back and wait until the astonishing range of diversification mechanisms adopted by different groups of vertebrates has been more fully explored.

I agree with the point of view expressed by Cohn in his introduction (and by Burnet before him), that ideas matter in immunology, perhaps more so than in other branches of biology, and that their most important function is in organizing otherwise incoherent sets of observations. But they need to be used with discretion and flexibility. Cohn criticizes others for their intellectual rigidity over the years, but it seems to me that the account of immunology that is presented here lays Cohn and Langman open to precisely that charge. □

Shell show

Tim Halliday

Turtles of the World. By Carl H. Ernst and Roger W. Barbour. *Smithsonian Institution Press: 1989. Pp. 313. $45.*

Such is the rate of decline of turtles and tortoises that we may never have the opportunity to learn more about many of them than is presented in *Turtles of the World*. The pictures shown below are reproduced from the book, which is the first to provide comprehensive coverage of the world's 257 turtle species, a group of reptiles with a 200-million-year history.

Each species is covered under the headings of description, distribution, habitat and natural history. There is considerable variation in the amount of material presented under the last heading, reflecting the fact that the behaviour and ecology of some species have been studied intensively, whereas little is known about others. The species entries are organized taxonomically and the book also includes detailed keys to identification at the levels of family, genus and species.

The most distinctive feature of turtles is the shell which, for most species, provides a protective haven into which the limbs and head can be withdrawn when the animal is threatened. There is considerable variation, however, in its form and protective role. In the softshell turtles, such as *Apalone spinifera* and *Cycloderma frenatum*, the amount of bone in the shell is greatly reduced, and the main means of defence is to burrow in sand or mud. The head of the Asian big-headed turtle *Platysternon megacephalum* is so large that it cannot be withdrawn into the shell; this species appears to compensate for its greater vulnerability by being nocturnal. The evil-tempered Mexican giant musk turtle *Staurotypus triporcatus* is able to keep its jaws open even when the head is withdrawn, making it a formidable adversary. The shells of many turtles are beautifully patterned and coloured, as in the spotted turtle *Clemmys guttata*.

Turtles face a number of threats. Many species make very good eating, others have been adversely affected by insecticides and herbicides. They frequently suffer heavy casualties on roads and the populations of several species have been severely reduced by the pet trade. Being generally long-lived and slow-breeding, turtles and tortoises are also vulnerable to high levels of hunting. Some are at their most exposed when the young leave the eggs, dig their way out of the earth and find their way to water. Aquatic species have to wait until conditions are wet and the young of the Australian giant snake-necked turtle *Chelodina expansa* have been known to be trapped underground for nearly two years by drought.

Turtles of the World represents an impressive piece of scholarship. For the specialist it will prove to be an invaluable source of information for many years. □

The *Almanac* man

Jack Meadows

Nevil Maskelyne: The Seaman's Astronomer. By Derek Howse. *Cambridge University Press: 1989. Pp. 280. £40, $59.50.*

THE Royal Observatory at Greenwich played a central role in British astronomy for three centuries. Yet there are few modern biographies of the Astronomers Royal, those king-pins of the astronomical establishment. This may be because the kind of work that traditionally occupied much of their time — positional astronomy — has had a rather poor press over the past few decades. One of the marvellous quotes in Derek Howse's book comes from an Assistant at the Observatory in the eighteenth century:

> Nothing can exceed the tediousness and ennui of the life the assistant leads in this place, excluded from all society. . . . Here forlorn, he spends days, weeks, and months, in the same long wearisome computations . . . He is also up frequently three or four times in the night.

These bitter comments reflect only too well the image that a modern astrophysicist has of the olden days. This new biography of the fifth Astronomer Royal, Nevil Maskelyne, shows that both he, and most of his assistants, had much more interesting lives. One reason was that astronomy in the eighteenth century had a greater strategic significance than it has today. As the book's subtitle indicates, astronomers were the chief advisors to governments on how to navigate accurately at sea — a limiting factor for all long voyages at that time. Although the Royal Observatory had been set up by Charles II primarily to find a means of determining longitude at sea, that aim had still not been achieved by the mid-eighteenth century. Maskelyne's historical importance was that two practical navigational techniques were developed during his period in office. His own contribution was the development of an almanac which allowed position at sea to be determined from the position of the Moon in the sky. This *Nautical Almanac* was an essential item for ocean-going ships until after the Second World War.

Ann Ronan Picture Library.

Nevil Maskelyne (1732 – 1811).

As befitted his post, Maskelyne had some involvement in most of the principal astronomical advances in the latter half of the eighteenth century. His best-known work was his measurements of Schiehallion, a mountain in Perthshire, which he used as a means of estimating the density of the Earth. As Howse says, the analysis may have involved the earliest application of contour lines (although the French might dispute this). In another chapter, we are given the full story of Maskelyne's uncomprehending discovery of the personal equation. Similar fascinating details occur throughout the book — for example, Maskelyne's dealings with Captain Cook, Sir Joseph Banks and assorted quarrelsome clockmakers, or how Mason and Dixon came together to measure their line in the United States.

This is as good a scientific biography as one could wish to have — fully documented, well illustrated, yet written throughout with a light touch. It provides an excellent insight into the world of British astronomy some two centuries ago. □

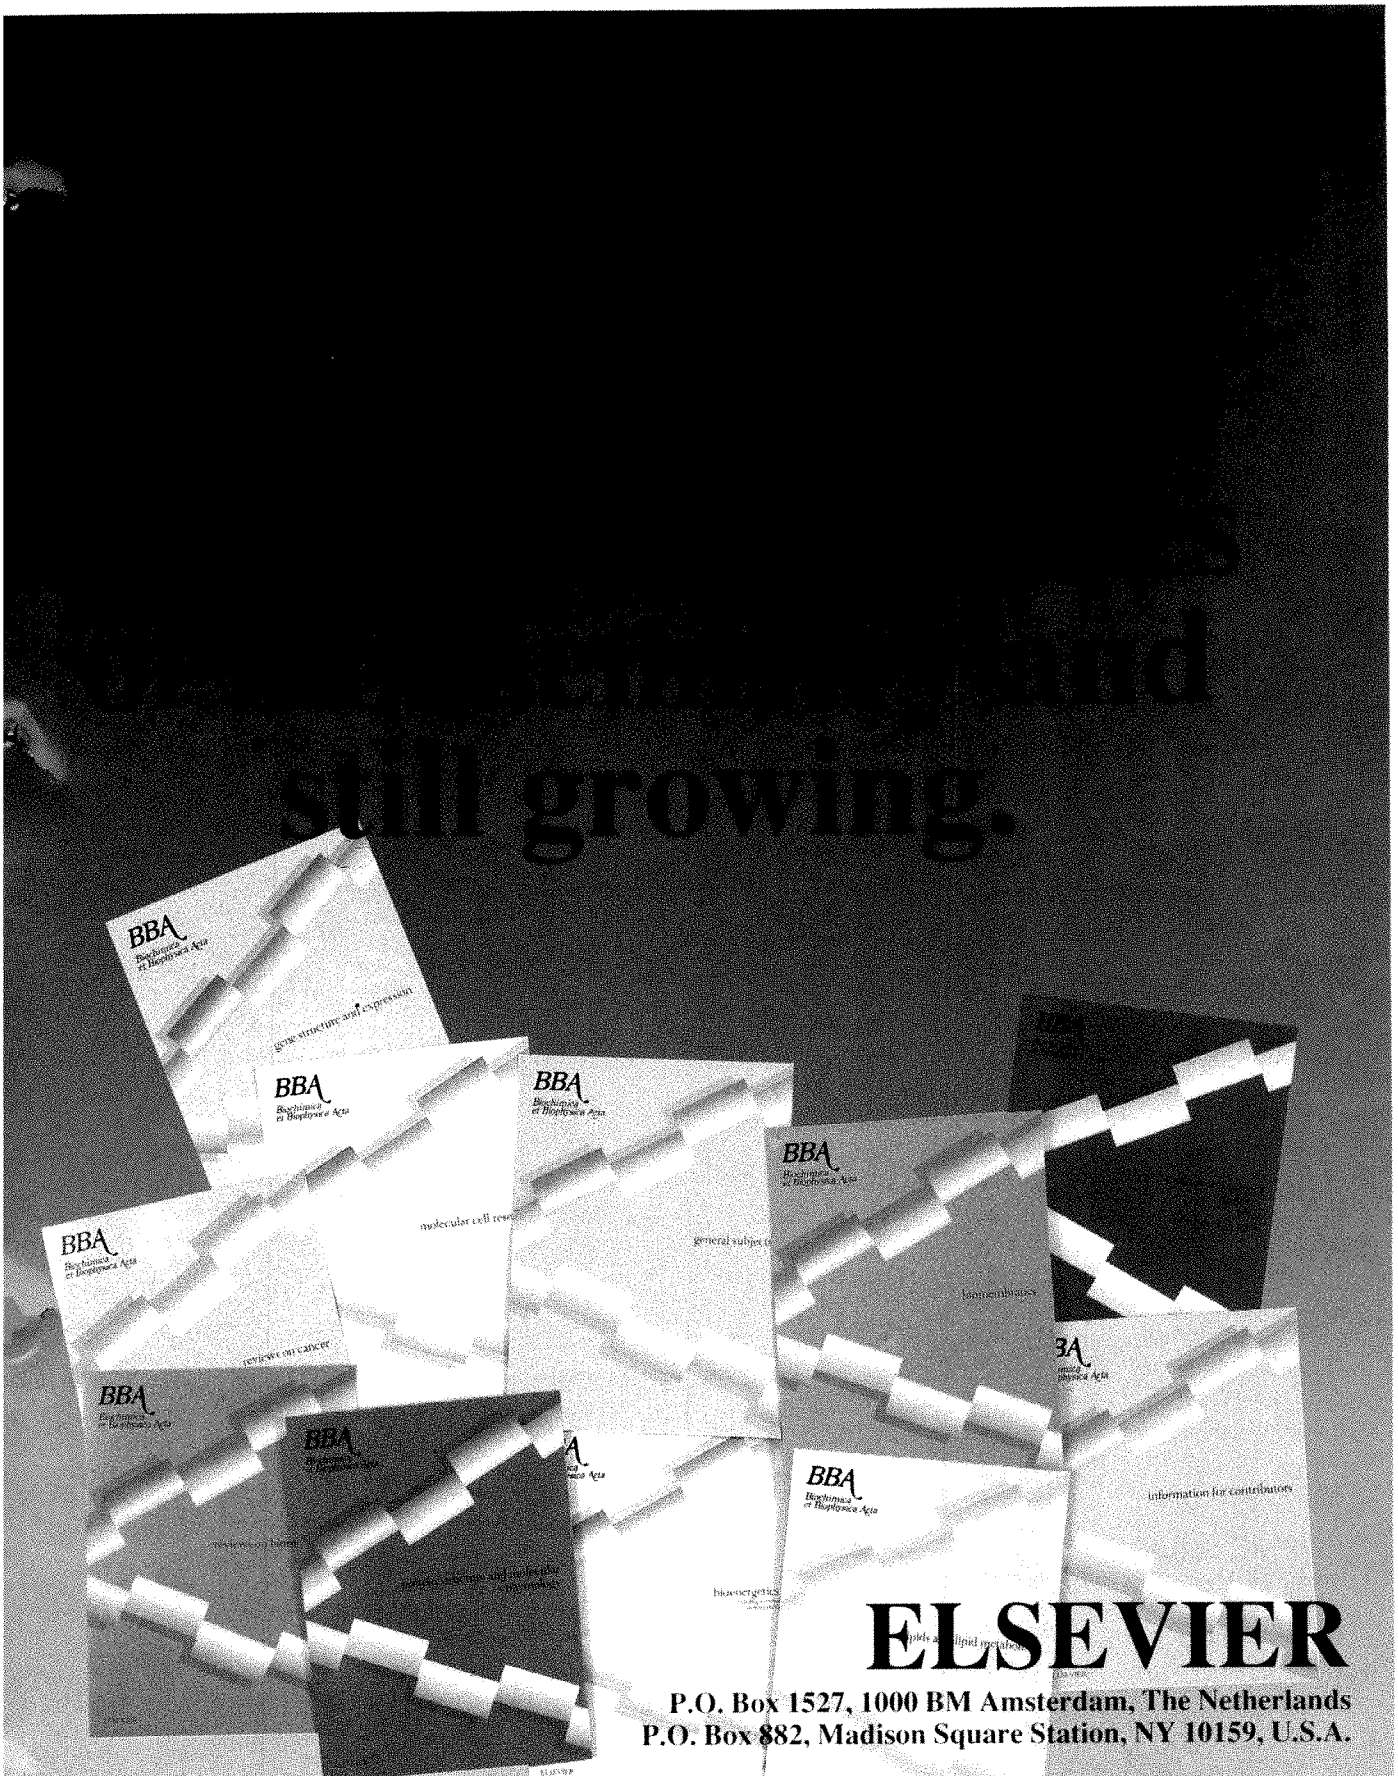
The good bits

William H. Press

The Turing Omnibus: 61 Excursions in Computer Science. By A.K. Dewdney. *Computer Science Press: 1989. Pp. 415. Distributed by W.H. Freeman, $24.95, £22.95.*

WE at universities like to have some idea — if only of the vaguest sort — of what our colleagues in other departments actually do. Most of us have a faint glimmering of what biochemistry, say, is about, or sociology, or Sanskrit or statistics. But what of that brash new department, computer science?

A seemingly benign computer scientist was on one occasion approached at an interdisciplinary, and well-lubricated, academic function. "Just as physics studies reality", he declared, "computer science studies *artificial* reality". Somehow this is not the kind of explanation one is looking for.



Now comes A.K. Dewdney, a computer scientist at the University of Western Ontario, with just the kind of answers that we need. *The Turing Omnibus* is full of wit — both kinds — from the double-barrelled pun of its title, all the way through its 61 short chapters, each of which amounts to a short essay, five or six pages long, on a particular topic in computer science. The "good bits" of computer science, Professor Dewdney cannot resist calling them.

This is a light-hearted but by no means light-weight volume — a book that 'does' Gödel's theorem in seven pages is no easy read. Although there are few mathematical proofs as such, there are a lot of summaries of the essential arguments of important proofs, algorithms and constructions. Thus we have wonderfully concise discussions of language hierarchies (regular versus context-free and so on), error-correcting codes, NP-completeness, tomographic algorithms, hashing, linear programming, minimum spanning trees, the knapsack problem, lambda calculus, neural nets — plus (literally) hundreds of additional concepts, because several ideas are frequently covered in a single short chapter. The "good bits", indeed! There is a detailed index. If its prose style had been turgid instead of informal, its visual design scholastic instead of amiable, *The Turing Omnibus* could have called itself *Short Encyclopaedia of Computer Science* and it would have elicited generally warm reviews.

Against this praiseworthy background one must, however, mention a serious deficiency: technical accuracy, or 'fact-checking', of the book is not up to the standard of a credible short encyclopaedia, or a first-rate textbook. For example, the discussion of probabilistic tests for primality, while it gets the spirit of the idea right, states the algorithm incorrectly. Another example: the account of cubic splines seems to miss the point that they are smooth in their *second* derivative and that they are global, not local.

These kinds of slips — there are some others — make *The Turing Omnibus* much less useful than it might otherwise have been; researchers in related fields, or students, would be ill-advised to rely on it as a one-volume reference work (as the author suggests in his preface). Such a caveat in no way diminishes its charm and usefulness in a limited niche, however. It is nearly the perfect book for non-computer scientists who want to learn something about the field, for undergraduates who want a detailed snapshot of what their prospective major field is about, or even for the bright secondary school student whose imagination will be fired up by a book that shows that there can be diverse, deep *ideas* inside computers — and no small amount of challenging intellectual fun. □

European Journal of Cell Biology

50 Volumes in 20 Years

on modern aspects in cell biology

The European Journal of Cell Biology has moved from a leadership position in Germany and Europe to being a renowned international Journal in this fast moving and important field of science. The journal is devoted mainly to studies in cell and molecular biology using animal, plant and protistan cells. Original research papers as well as review articles on aspects of cellular dynamics, differentiation, biochemistry, immunology, and molecular biology in relation to structural data as well as methodologically oriented manuscripts concerning significant technical advances are published in English language. In addition, biomedical manuscripts which are of general cell biological interest are published. A truly international board of editors and co-editors includes scientists from thirteen countries which cover a wide spectrum of cell biology disciplines.

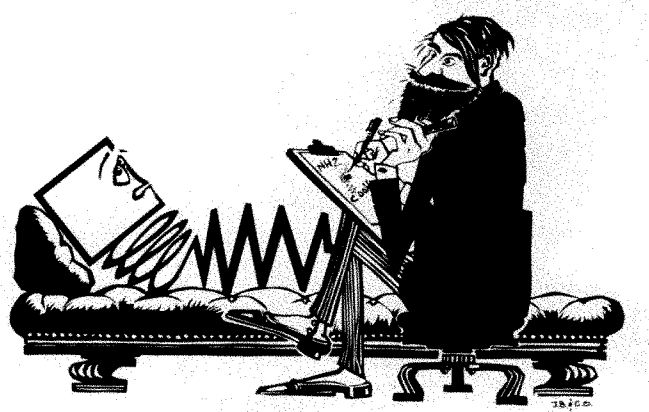
The high publishing standards of German craftsmanship have always characterized EJCB papers. Micrographs, as well as line drawings and tables, are reproduced with the highest quality attainable. Expert reviewing is done with dispatch and with the goal of aiding authors in presenting their findings and conclusions clearly and appropriately.

Papers will be published without page charge (except color prints) within two to four months after their final acceptance.

Abstracts of cell biology meetings published in Supplement issues are distributed at no extra charge to subscribers of the journal.

The format of the journal is 21 × 28 cm.

The issues will subsequently be published bimonthly in volumes of about 400 pages. The price per volume is DM 356,— plus postage, the price for a single issue depends on size, i. e., number of pages.



- no price increase for 1990
- no page charge for publication
- international expert reviewing of manuscripts
- rapid publication within 2 to 4 months
- highest standard for reproduction of micrographs
- Abstracts of cell biology meetings in Supplement issues distributed at no extra charge to subscribers

Why not do it your way?

The *NEW* IBI Pustell for IBM-PC and MacVector for Macintosh from Blackwell Scientific Software

20% discount for academic purchasers

MacVector and the new IBI Pustell are nucleic acid and protein sequence analysis systems that can turn your desktop into the most productive place in your laboratory. MacVector and IBI Pustell set out to give you an edge that you may not have found before in sequence analysis software: what **you** want.

- You want it to run on a Macintosh® — IBI MacVector does.
- You want it IBM-PC® and PS/2®-compatible, with a mouse — IBI Pustell is.
- You don't want it to be missing vital functions you would take for granted (like using GenBank format and converting sequences between this and other formats). It won't: both IBI Pustell and MacVector are *comprehensive*.
- You don't want to sacrifice the speed you are used to — you don't have to: you can search the whole of GenBank in an hour, and NBRF in minutes, *at your desk*.
- You probably want it to be (tricky now) inexpensive — well, almost, but choosing IBI Pustell or MacVector won't flush the budget down the sink like some alternatives, and academic purchasers get a 20% discount.

Above all, you want the software to do what you want — where and when you want it — and you want back-up and technical help, should you need it, from the people who sold it to you. Rest assured: Blackwell Scientific Software will be there with trained support staff.

Turn the page to find a summary of IBI Pustell's and MacVector's specification. You should find just about everything you need, and if you don't, let us know. This new software is very largely the result of recommendations from other researchers. Your suggestions will be equally valuable, because IBI Pustell and MacVector are designed for the researchers who use them — to let *you* do it *your* way.

The basic price for IBI Pustell or MacVector is just £1750, and if, as well as everything else, you want your copy *now* — then call our hotline number.

At your service,
BLACKWELL SCIENTIFIC SOFTWARE

PRICES

£1750 for a single installation. Academic purchasers qualify for a 20% academic discount, worth £350, off this price. Extra copies of the software for registered use at the same laboratory can be purchased at a reduced rate.

UPGRADES

If you are already using a previous version of IBI Pustell, now is the time to claim your upgrade. If you send in your original system disks from the version you are using now, your order will be processed at £325. (There is no academic discount on this price.)

HOTLINE

Call Peter Kibby on 0865 (UK) or +44 865 (elsewhere) 240201 for immediate service.
Fax: 721205 or 791738 (24 hours).

Blackwell Scientific Publications

CONCISE IBI PUSTELL AND MACVECTOR SPECIFICATION

UNIQUE FEATURES OF IBI PUSTELL/MACVECTOR

Accepts GenBank®, Staden, Bionet®, UWGCG and ASCII sequence formats and converts files between these formats.

Displays not just the sequence but all annotations and references contained in a database, all of which can be searched — including wildcard searches — and which are adjusted automatically as you edit the sequences they refer to.

- Automatically searches **both** strands of a DNA sequence.
- Automatically allows for gaps and deletions in searches.
- 20% off regular price to recognised academic institutions.

RESTRICTION ANALYSIS

IBI Pustell/MacVector includes a file of restriction enzymes commercially available at the time of "going to press". The analysis programs offer cleavage and fragment prediction and mapping in two phases. In phase one you generate all potential data by including any or all of the available enzymes in the digest. In phase two, choose up to six enzymes at a time and present your data by their names, cut sites, the number of cuts or the sites, sizes or end-structures of the cuts or by specific reading frames. Cut sites can be selected and saved to the feature table stored for each sequence. You can show important features of each sequence with a graphical map of the analysis.

SEQUENCE ASSEMBLY

IBI Pustell/MacVector performs random sequence assembly by finding overlaps in — for example — gel readings, without recourse to specialist programming. First the selected sequences are combined into one long sequence; then matches of one part to another within it are found by using IBI Pustell's powerful homology programs. The search parameters are under your control, so their stringency can be adjusted to suit exactly the project in hand. Possible overlaps that are found in this way can then be further scrutinized with other homology matrices or with the sequence alignment/consensus programs. The software's flexible sequence editor facilitates rapid final manipulation of the chosen parts of the sequence into one continuous piece.

IMPORTANT BENEFITS FOR IBI PUSTELL/MACVECTOR USERS

- IBI Pustell's/MacVector's reformatting of sequence data helps you use data downloaded from mainframes or online databases, and encourages the transfer of sequence data back to a mainframe.
- Optimization of homology searching "finds significant homologies missed by other programs" *(Biotechnology Software)*
- Searches put no limit on the size of the search sequences, and only require hard disk space sufficient to hold the sequences themselves (*eg* 5-Mbytes for a 5-Mbyte sequence file).
- IBI Pustell/MacVector defaults to the universal genetic code, but you can easily change to alternate codes.
- Database management is fully integrated with analysis functions.
- Concise and intelligible documentation, which is augmented by access throughout the programs to online help, plus the intelligent user interface, rapidly has new users "up and running".
- The software accepts sequence data directly from the IBI Gel Reader (available separately from IBI).
- Unlimited, after-sales technical support is available from skilled Blackwell Scientific Software staff.

HOMOLOGY COMPARISONS

IBI Pustell/MacVector uses two-dimensional, matrices to compare two sequences — nucleic acid to nucleic acid, amino acid to amino acid or nucleic acid to amino acid — by indexing one sequence on the x-axis and one on the y-axis of a graph. You can increase the sensitivity of comparisons with a weighting scheme that establishes different levels of similarity. All the homology criteria are set by you, the user. Initial DNA comparisons automatically search both strands and let you display them + + or + − in your matrix.

PROTEIN CODING REGION LOCATION

IBI Pustell/MacVector locates protein coding regions by searching for ORFs using start and stop codons you define or by Fickett's Testcode statistical method of codon bias. Once found, selected ORFs can be saved to the sequence's features table for later use.

THE PROGRAMS THAT COMPRISE IBI PUSTELL/MACVECTOR

- Set up defaults (for alignment of sequences, genetic codes, file formats, display, printers and passwords)
- Database manager (access to databases and file management; offers searches by sequence name, database subdirectory, keyword, author's name, organism name, human gene map symbol, journal title and year, accession (GenBank) or EC (NBRF) number)
- Nucleic acid/protein sequence editors (edit both the sequence and the annotations, with automatic movement of annotations if the sequences they refer to are moved; hold up to ten files in memory for creating plasmid maps)
- Nucleic acid/protein subsequence editors
- Nucleic acid/protein subsequence analysis (ideal for finding CAP sites, TATA boxes, phosphorylation and glycosylation sites and DNA binding regions)
- Restriction/proteolytic enzyme editors
- Restriction/proteolytic enzyme analysis (see box opposite)
- Calculate/plot base composition (mono-, di- and tri-nucleotides analyses, with strand assymetry)
- Calculate AA composition, pI, molecular weight
- DNA/protein homology matrices (see box opposite)
- Search nucleic acid database with a nucleic acid (derived from FastN method; automatically searches both strands of DNA simultaneously; approx 1 hr to search whole GenBank database on a Mac II)
- Search nucleic acid database with a protein (up to 1000 AA search sequence, translating both strands of database nucleic acid into all six possible reading frames)
- Search protein database with a protein (based on FastP; searches entire NBRF database in a few minutes on Mac II with hard disk)
- Translate: nucleic acid to amino acid (codon usage)
- Reverse translate: protein to nucleic acid sequence (determining the least redundant DNA probe of user-designated size)
- Compute antigenic index of a protein (surface contour prediction from combination of secondary structure, flexibility, surface probability and hydrophilicity predictions; Jameson and Wolf method)
- Protein coding region locator (see box opposite)
- Protein secondary structure prediction (Chou-Fasman, Robson and Garnier, and combined, methods)
- Plot hydrophilicity of a protein graphically (based on Kyte and Doolittle method)
- Plot surface probability of a protein graphically (uses solved crystallographic structures as its data set; Emini, Hughes, Perlow and Boger method)
- Plot flexibility of a protein graphically (Karplus and Schultz method)

IBI Pustell and MacVector are manufactured by IBI — a Kodak company. IBM PC and PS/2 are registered trademarks of International Business Machines Corporation, Macintosh is a registered trademark of Apple Computer, Inc, BIONET of Intelligenetics and GenBank of the National Institutes of Health. Kodak is a registered trademark.

Adaptation, speciation and hybrid zones

N. H. Barton & G. M. Hewitt

Many species are divided into a mosaic of genetically distinct populations, separated by narrow zones of hybridization. Studies of hybrid zones allow us to quantify the genetic differences responsible for speciation, to measure the diffusion of genes between diverging taxa, and to understand the spread of alternative adaptations.

HYBRID zones are narrow regions in which genetically distinct populations meet, mate and produce hybrids[1,2]. They are found in all major groups of higher organisms, and divide species into a patchwork; adjacent regions can be distinguished by every kind of character from nuclear and cytoplasmic DNA, allozymes and chromosomes to colour pattern, morphology and behaviour. Because the hybridizing populations exchange genes, and yet remain distinct, they have long perplexed taxonomists. A biological species is defined as an "actually or potentially interbreeding group of populations"[3]; any taxa that can produce viable and fertile F2 generations or backcrosses are regarded as being of the same species. But taxa that remain distinct despite gene exchange have in fact been classified as separate species even by the originators of the biological species concept[3-5]. Thus there is a clash between two views of species; one is based on the pattern of gene flow, and the other on the maintenance of a cluster of phenotypes that is stable to invasion by foreign genes.

Although it can confuse attempts at rigid classification, the conflict between gene flow and selection towards alternative stable equilibria gives us insight into both processes. Hybrid zones are especially well suited for testing the view that adaptation involves a 'shifting balance' between selection on individuals, and selection on whole populations[6]. This view, which was first advanced by the influential American biologist Sewell Wright in the 1930s, holds that selection between individuals leads populations to local optima or 'adaptive peaks', but that further progress requires that different regions reach different peaks, and that superior peaks then spread through a form of group selection.

Hybrid zones are natural laboratories that can tell us about the nature and effects of differences among incipient species, and about how selection at different levels affects the spread of alternative adaptations. We will first summarize a survey of over 70 hybrid zones, emphasizing the common features shared across diverse groups. We will then show how mathematical models can be used to measure the genetic basis of reproductive isolation, and to understand the spread of different adaptive peaks.

General patterns

Populations separated by hybrid zones may differ greatly, or hardly at all. Sometimes only a few genes seem to be involved; for example, the races of the mimetic butterfly *Heliconius erato*, which hybridize in South America, differ by between one and six major genes affecting wing pattern. No biochemical divergence or reproductive incompatibility has been found[7]. In other cases, the taxa may differ in almost every respect. For example, the fire-bellied toads *Bombina bombina* and *B. variegata* interbreed freely in a narrow zone that runs for 1,000 km through eastern Europe. But they differ in mating call, warning coloration, life history, preferred habitat, enzymes and mitochondrial (mt) DNA; their biochemical differences indicate that they have been diverging for 3–4 million years[8].

Some patterns do emerge from this diversity. Most hybrid zones are narrow relative to the species' range, and to the distance moved in a generation, σ: the majority of zones are less than 50σ wide[1]. (The dispersal rate, σ, is defined as the standard deviation of the distance between parent and offspring along a chosen axis; it has units of distance time$^{-1/2}$; $\sigma^2/2$ is analogous to a diffusion coefficient.) In the *viatica* group of morabine grasshoppers, for example, one chromosome arrangement may be replaced by another over less than 20 m (refs 9, 10). In the land snail *Cerion*, different shell morphs can be separated by as little as 100 m (ref. 11).

Most zones involve changes in a variety of characters, and so consist of a cluster of parallel gradients in gene frequencies (these gradients are termed 'clines'). It is not simply because complex zones are more easily detected that multiple differences are seen so often. On the contrary, zones that are first identified through characters such as plumage or chromosome arrangement are usually found later to involve biochemical differences. On average, 18% of enzyme loci show substantial frequency differences, and Nei's genetic distance averages 0.26 (samples of 46 and 34 zones, respectively). This suggests that divergence is ancient— ~1 million years if a rough molecular clock is assumed[12]. Because hybridization may dilute biochemical differences, this could be an underestimate.

The different clines which make up a hybrid zone usually coincide. For example, where the toads *Bombina bombina* and *B. variegata* meet in southern Poland, clines in allozymes, belly pattern, mating call and mtDNA differ in position by less than 30% of their average width, and vary in width by at most 27% (ref. 8, and similar additional data; cline width is defined throughout as 1/maximum gradient). Of all the continuous transects studied so far, characters encoded by nuclear DNA are significantly displaced in only four[13]. Hybrids can be found in mosaic distribution, such as those of the crickets *Gryllus firmus/pennsylvanicus* in Connecticut[14]. Even here, however, the correlation between different characters can be quite close. (The average pairwise correlation among five biochemical markers in 16 sites is $r = 0.49$.)

Mitochondrial DNA often shows a different pattern. For example, all the nuclear genes that distinguish the house mice *Mus musculus musculus* from *M. m. domesticus* change together in Jutland[15]. By contrast, one mtDNA from *M. m. domesticus* has penetrated about 750 km north into Sweden[16] (although this has not happened in other parts of the zone[17]). Several other cases of such discordance are also known (for example see refs 18, 19). Discordance may arise by introgression through stable hybrid zones, or from occasional founder effects[10,16]. Mitochondrial DNA may differ from nuclear genes because selective interactions between mitochondrial and nuclear genes are weaker than those among nuclear genes, and because mitochondria segregate independently of chromosomes[19]. The difference, however, may appear simply because phylogenies of mitochondrial sequences can be determined relatively easily. Moreover, the different patterns are not incompatible: recent differences may change together in a sharp hybrid zone, whereas more ancient differences may have introgressed[17,18].

There are often strong associations ('linkage disequilibria') between genes, chromosomes and morphological characters coming from the same parental populations. These are generated by the continual diffusion of parental combinations of genes into the centre of the zone and are broken down by recombina-

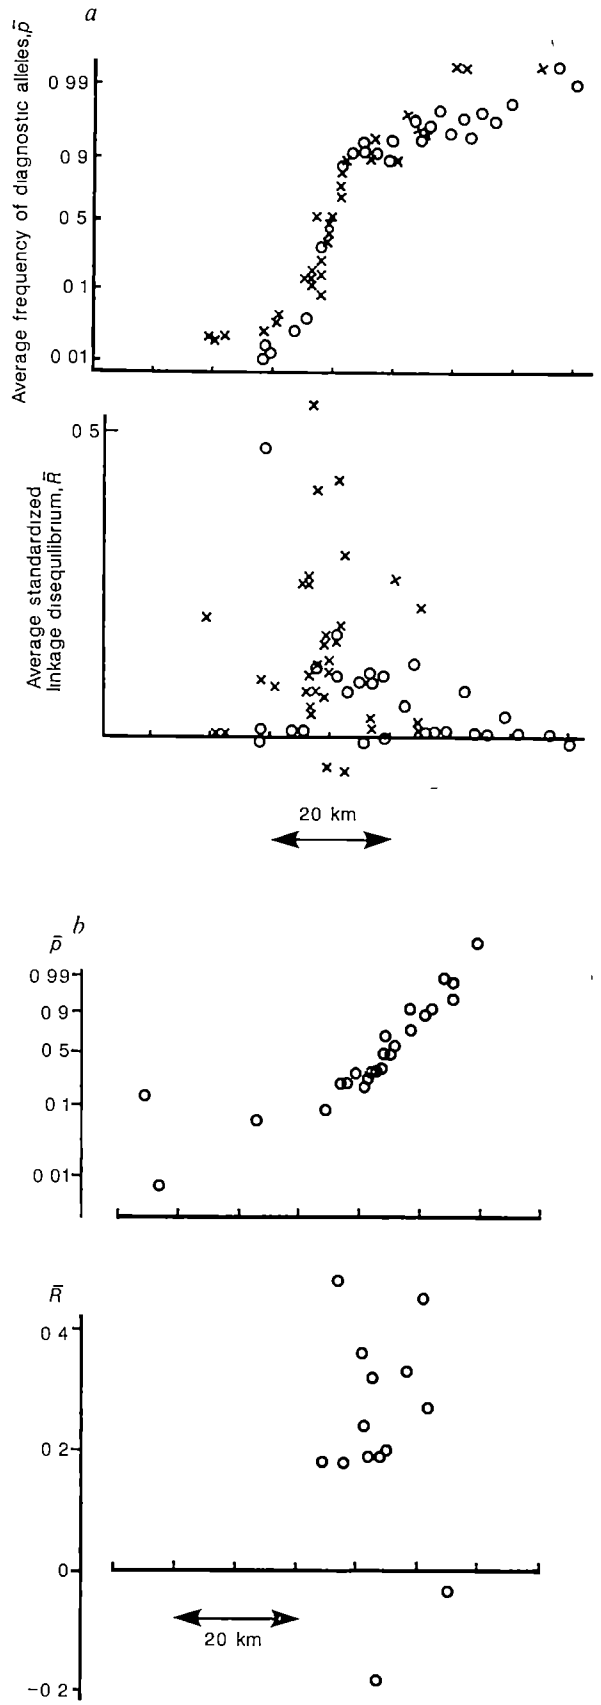

FIG. 1 Graphs of the average frequency of diagnostic alleles, $\bar{p}$, and the average standarized linkage disequilibrium ($\bar{R}=D/\sqrt{p_1q_1p_2q_2}$) across two hybrid zones *a* Fire-bellied toads, *Bombina bombina/variegata* in southern Poland (data from ref 8, together with new data, six enzyme loci. Crosses. Cracow transect Circles Przemysl transect) *b*, Butterflies *Heliconius erato* in Peru, three wing-pattern loci (Mallet, personal communication)

tion and segregation in hybrids. Disequilibria can hence give an estimate of the rate of diffusion, σ (ref. 20). For example, where the Tarapoto and Amazonian races of the butterfly *Heliconius erato* meet and hybridize in Peru, there are significant disequilibria between all three loci involved, even though these are on different chromosomes (Fig. 1*b*). These give an estimated dispersal rate of $\sigma \approx 2.4$ km generation$^{-1/2}$. This indirect method of measuring genic diffusion gives values higher than those from studies of individual movement ($\sigma \approx 0.3$ km generation$^{-1/2}$ in *H. erato*[21]). Because direct measurements often miss long-distance migrants and sporadic population movements[22], the indirect measures may be more accurate. The discrepancy could also arise if associations are built up by selection for particular gene combinations, as well as by diffusion. But the error should not be more than twofold even for a pair of clines maintained entirely by selection for particular gene combinations; with more loci the effect becomes negligible[23].

What maintains hybrid zones?

We believe that most hybrid zones are in fact 'tension zones'[24], which we define as clines maintained by a balance between random dispersal and selection against hybrids[1]. Before describing the evolutionary significance of tension zones, we will briefly explain our reasons for this opinion.

Most zones involve strong selection, as is made manifest by the finding of hybrid inviability or sterility in the field[25-29] or laboratory[8,30-34], the elimination of individuals[35] or chromosomes[31] moved across the zone, comparison between age classes[33], or, less directly, chromosome aberrations[31,36,37] or morphological anomalies[8] in hybrids. Evidence also comes from the strong associations between different loci, which must ultimately be maintained by selection—mixing can only produce strong and persistent linkage disequilibria if selection maintains steep gradients in gene frequencies. Finally, clines are often narrow relative to the dispersal range. For example, in the hybrid zone between the grasshoppers *Chorthippus parallelus parallelus* and *C. p. erythropus*, the nucleolar organizer changes over less than 600 m at Col de la Quillane, and parts of the song of the grasshoppers also change sharply[38]. These races have been in contact for at least 8,000 generations, a period long enough to produce a cline more than 7 km wide if they had been mixing at the observed rate of $\sigma \approx 30$ m in a generation. Selection must therefore be acting on these characters, a conclusion supported by the fact that other clines in the same hybrid zone are much wider (~15 km for allozymes, and ~4 km for the stridulatory pegs[13]).

Is selection in hybrid zones a direct response to environmental variation, or does it instead reflect the intrinsic inferiority of hybrids? It is conceivable that selection actually favours hybrid genotypes in particular environments[39]. But this would not account for the typical composition of hybrid populations: one would expect that only a few hybrid genotypes would dominate, as when hybrids reproduce parthenogenetically or by self-fertilization (for examples see refs 40, 41). By contrast, hybrid zones contain a mix of gene combinations, with associations of similar magnitude between all pairs of genes (for example, *Heliconius* (Fig. 1*b*); see also refs 15, 20, 42, 43). The superiority of hybrids in particular environments also cannot account for the long, narrow strips of roughly even width that are typical of most zones (see for example Fig. 3*a*).

It is difficult to distinguish between other possibilities. The selection that maintains a hybrid zone could favour different alleles in different places, or it could act against hybrids. For either case, the shape of the cline would be similar (Fig. 2): alleles that cross the cline would be eliminated either because they were in the wrong environment, or because they were combined with the wrong genes. Frequency-dependent selection against rare alleles would have effects similar to those of selection against hybrids[21,44,45]. Where zones in several species coincide, interspecific interactions might also maintain clines.

Finally, all these kinds of selection might act in the same zone. For example, selection against heterozygotes, recombinants and rare morphs, together with interspecific mimicry, act to maintain homogeneous warning patterns in *Heliconius* butterflies[21]. (See also refs 8, 43, 46.)

Although there is evidence for adaptation to local environment from many zones[1,2,13], selection against hybrids is probably more important in maintaining them. First, different clines often coincide very closely; if each allele were to respond directly to the environment, such geographic concordance would not be expected, even allowing for the effects of linkage disequilibrium[47]. Second, even if differences were established as an adaptive response to environmental differences, subsequent coadaptation would be likely[48,49]. For example, the evolution of tolerance to heavy metals in plants is sometimes accompanied by partial reproductive isolation[50]. In the monkey flower *Mimulus guttatus*, a perennial plant found, in addition to other places, along the banks of streams on disused open-cast mines in North America, one tolerance allele is incompatible with an allele at another locus in the original population[51]. Although it is difficult to understand just how incompatibility between differently adapted races arose[52], it seems likely that clines that are initially maintained solely by differential adaptation will, as more differences accumulate, develop into tension zones which can be maintained even without the original environmental difference[1,2,13].

The mathematics of tension zones

All but the simplest types of natural selection lead to multiple stable equilibria: populations may respond to the same selection pressures by evolving different combinations of genes. At the boundary between populations in different stable states, a balance between random dispersal and the disruptive attractions of alternative equilibria usually maintains a narrow cline.

Bazykin[53] suggested the simplest model of a tension zone. Heterozygotes have fitness $1-s$ relative to either homozygote. If the allele frequency is p, the change in allele frequency is then (for small s)

$$\frac{\partial p}{\partial t}=\frac{\sigma^2}{2}\frac{\partial^2 p}{\partial x^2}+spq(p-q) \qquad (1)$$

where $p+q=1$. This equation has the solution $p=1/(1+\exp[-(x-x_0)/l])$, where $l=\sqrt{\sigma^2/2s}$ is the characteristic distance over which selection changes allele frequencies; the cline width is $4l$.

In this model the environment is homogeneous and the homozygotes have equal fitnesses, so the cline can form anywhere (x_0), and the equation has a family of neutrally stable solutions. These are known as 'topological solitons'[54]—solitary waves set up at the boundary between two regions constrained to be in different states. The same phenomenon (often the same equation) arises in many other fields (see refs 55–59.) Bazykin's model is based on a special kind of reaction–diffusion equation[60], in which attention is centred not on the spontaneous formation of pattern from a homogeneous field (as in Turing's model[61]), but on the interaction between areas which have moved to different states. Indeed, the boundary between regions at high and low concentrations in the Turing model behaves in a similar way to the tension zone.

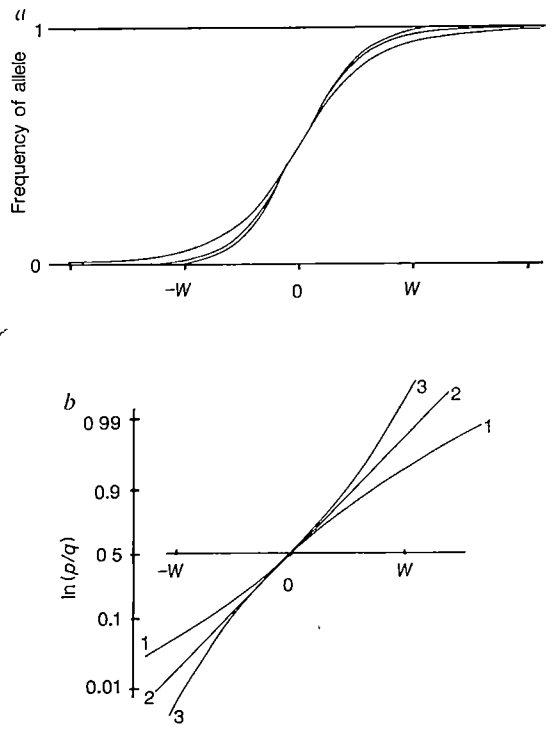

FIG 2 *a*, Clines maintained by a balance between dispersal and selection will have similar sigmoidal shapes. *b*, Transformation to a logit scale [$\ln(p/q)$] reveals differences in the shape of the tails; because these involve extreme gene frequencies, however, they can only be detected with large samples. If cline width is defined as $w=1/$(maximum gradient), the graphs are scaled so that all clines have the same width. Three cases are shown: (1) selection, $-s$ on one side of a sharp environmental change, $-s$ on the other ($w=\sqrt{6}l$); (2) heterozygote disadvantage ($w=4l$), and (3) introgression of neutral alleles for T generations ($w=\sqrt{4\pi T}l$, where $l=\sigma/\sqrt{T/2}$.

Barriers to gene flow

Although gene frequency can change abruptly across the centre of a hybrid zone, foreign alleles can still penetrate far into either side. This gene flow between distinct populations binds them together into one biological species. In *Bombina*, although the average frequency of diagnostic enzyme markers changes by ~90% over 6 km, foreign alleles have been found up to 38 km from the centre of the zone (Fig. 1*a*). If this was due simply to a few long-distance migrants, parental and F1 genotypes would be expected to be found well outside the zone; strong linkage disequilibrium would also be expected there. This is not the case for *Bombina*. In other studies data are not yet available to rule out this possibility.

Smooth sigmoid clines are expected for introgressing alleles that are diffusing freely or are subject to only weak selection (Fig. 2). A barrier to gene flow, caused for example by a physical obstacle, will produce a step in gene frequency, Δp, at the centre of the cline proportional to the gradient ($\partial p/\partial x$) on either side[62]. The strength of the barrier can be estimated from the shape of the cline as $B=\Delta p/(\partial p/\partial x)$. This measure has the dimensions of distance, and its magnitude relative to the dispersal rate (B/σ) determines the delay to the spread of genes across the barrier. Although neutral alleles can suffer a lengthy delay [$T\approx(B/\sigma)^2$], alleles with even a slight advantage (S) will hardly be impeded ($T\approx\log[(B/\sigma)^2\pi S/2]/2S$). This is because once a few of them penetrate the barrier, they will increase exponentially and spread to fixation[63]. In making these comparisons it is important to note that even without barriers, neutral alleles will take ~10,000 generations to spread over ~100σ by diffusion alone. Because species' ranges are unlikely to remain stable for such long periods, neutral variants are much more likely to be carried long distances by gross population movements ('convection') than by local diffusion[1,3,22].

For example, the strength of the barrier to gene flow (B) from *Bombina bombina* to *B. variegata* is equivalent to 51 km of unimpeded habitat (support limits, 22–81 km). This compares with a dispersal rate (σ) of 0.99 km, and a cline width (w) of 6.1 km. (The figures here differ from those in ref. 8 because new data have since been included.) The barrier would delay neutral alleles for ~2,700 generations, which is about the same as the time for which the present hybrid zone has existed. The barrier

would, however, delay an allele with an advantage of 1% for only ~200 generations.

The barriers to gene flow revealed by sharp steps at the centre of many hybrid zones can be explained by linkage disequilibrium. At the centre, each allele is associated with others from its ancestral population. Selection acts, therefore, not on individual loci, but on correlated sets of loci. If the net selection pressure is great enough relative to the rates of recombination and segregation, strong selection can be induced on each locus by a 'hitch-hiking' effect[63]. A sharp gradient is produced, which in turn generates stronger linkage disequilibria and induces yet stronger selection[23]. But as foreign alleles introgress through the zone they will recombine into the new genetic background, and so will only be subject to selection arising directly from their own effects[23]. This argument leads to a general expression for the barrier strength, B, in terms of measurable quantities: mean fitness, average recombination rate and cline shape. When applied to *Bombina*[8], this expression shows that the barrier to gene flow can be explained by a reduction in mean fitness at the centre of the hybrid zone to 58% (support limits, 54-68%). Because this reduction is much larger than the selection required to maintain associations between particular pairs of enzyme loci, selection must act on many genes. The number of genes responsible for reproductive isolation between *B. bombina* and *B. variegata* can be estimated from this argument to be ~55 (support limits, 26-88). This estimate provides a rare insight into the number of loci involved in speciation.

The movement of tension zones

To understand how species form, and to judge the importance of Wright's shifting-balance theory in adaptation, it is crucial to know whether a tension zone can move from where it was first formed and, if so, what factors are important in determining its position. Because tension zones are maintained by interactions between genes, rather than in direct response to a heterogeneous environment, they are not held in any fixed position. They can be perturbed by local variations in population structure (that is, by population density and dispersal rate), and by adaptation to local environments.

Different kinds of perturbation can be summarized in a function ($\bar{H}$) of zone position, which tends to a minimum. In the panel on the left, we show how this potential function can be derived for the simple case of selection, s, against heterozygotes that we described in equation 1. Terms are added to allow for a selective advantage $2S$ of one homozygote over the other, and for variations in 'neighbourhood size' ($N = 4\pi\rho\sigma^2$, the product of density ρ and the dispersal rate). This function is easy to generalize to other selection schemes. The tension zone will move to minimize its length, and hence to eliminate any bulges in the zone. It will also move towards regions of low neighbourhood size, and so will come to rest at physical barriers to gene flow. Finally, any allele with a superior homozygote will tend to spread. These effects can be illustrated by a modified version of Wright's 'adaptive landscape', in which neighbourhood size (squared) is plotted against position; the tension zone can be pictured as a heavy elastic ring, which tends to roll down the surface, but also to contract into a smooth curve. If the equilibrium contained within the ring is superior, there will be an additional outward pressure on the ring.

In spite of the complexity of the forces that can move tension zones, some generalizations can be made. Because density and dispersal may vary greatly, even over short distances, the potential surface will be rough. Thus, unless one equilibrium is much superior to another ($S \approx s$), the zone will be trapped by local barriers. The zone could only move far from where it first formed through convective movements of the whole population. In the extreme, the species might become extinct over large areas; when conditions improved, the zone would form again in a new position. In less drastic cases, fluctuations in population density might push zones from place to place.

The two chromosomal races of the grasshopper *Podisma pedestris* may be considered as an example. These meet along the main ridge of the Alpes Maritimes (Fig. 3*a*), close to the line along which southern and northern populations are likely to have met after the last glaciation[13,28,64]. The zone fluctuates by a few kilometres on either side of the ridge, so that the races do not necessarily meet exactly at high passes (Fig. 3*b*–*d*). On a smaller scale, the zone usually runs along cliffs, streams, grazed areas, or other inhospitable regions. In at least two places, however, it bulges outwards (Fig. 3*b*, lower left; *d*, upper right). These anomalies can be explained by the local distribution of grasshoppers—the pressure of numbers on the concave side of the bulge balances the contraction of the tension zone[64].

MOVEMENT OF TENSION ZONES

THE effects of all the forces that perturb a tension zone can be summarized in a single potential, $\bar{H}$, which tends to a minimum. It is calculated relative to a natural geometry, with scales set relative to local rates of dispersal and selection. Suppose that genes move across a rough two-dimensional habitat. Dispersal may be anisotropic, in which case the dispersal rate σ^2 becomes a 2×2 matrix, with elements σ^{ij} giving the covariance between the distance moved in directions i and j. The dispersal matrix may vary between times and between places; this can be represented by measuring distance relative to the ratio between dispersal and selection against heterozygotes, and time relative to $1/s$. This gives a new coordinate system, in which the distance between two nearby points dx^i apart is $dX^2 = dx^i g_{ij}\, dx^j$ and the time interval is $dT = s\, dt$. A new (non-euclidean) geometry is defined by the metric $g^{ij} = 2\sigma^{ij}/s$ (tensor notation is used here. g_{ij} is the inverse of g^{ij}). Terms must also be added that represent the effects of variations in neighbourhood size ($N = 4\pi\rho\sigma^2$), and an advantage of one homozygote over the other[72]. Equation 1 becomes.

$$\dot{p} = \nabla^2 p + \nabla \log(N^2) \cdot \nabla p + pq(p - q + S/s) \qquad (1.1)$$

where ∇^2 is the Laplacian, which replaces $\partial^2 p/\partial x^2$ in two dimensions, and p is the differential with respect to (rescaled) time. Equation (1.1) can be rewritten in terms of a potential H (a rescaled version of the potential in ref. 72).

$$p = -\frac{1}{N^2}\frac{\partial H}{\partial p} \qquad (1.2)$$

where

$$H = \int \frac{N^2}{2}(\nabla p \cdot \nabla p + p^2q^2 + (S/6s)(p - q)(1 + 2pq))\, dX$$

If inhomogeneities are small, then we can assume that in most places the population is close to one or other equilibrium. The boundary between regions containing different alleles is then still approximated by the solution to equation (1), and will move slowly. Equation (1.2) can now be simplified, because only the position of the boundary need be followed, rather than the whole field of gene frequencies. The full potential H is replaced by $\bar{H}$, which is calculated on the assumption that the tension zone is close to its unperturbed sigmoid shape. If we measure distance along the zone by z, and if $y(z, t)$ is the distance between the centres of the zone at z at times 0 and t, then the rate of movement is (by the same method as in ref. 72)

$$\dot{y} = -\frac{6}{N^2}\frac{\partial \bar{H}}{\partial y} \qquad (1.3)$$

where

$$\bar{H} = \int \frac{N^2}{6}\, dz - \int \frac{N^2 S}{6s}\, dA.$$

This equation is a spatial analogue of Wright's formula for the evolution of a single panmictic population

$$\partial p/\partial t = (pq/2)(\partial \log(\bar{W})/\partial p)$$

The first term is an integral around the zone, and is proportional to the length of the zone, the second term is an integral over the area occupied by the allele with advantage S. In a finite population, this equation must be modified to take account of the fluctuations caused by random drift, which will tend to make the zone expand[65].

Speciation and the shifting balance

The movement of tension zones helps to determine the pattern of speciation, and the way species evolve genotypes that are better adapted. Because they reveal the extent to which species are divided into regions near different equilibria, tension zones are closely related to Wright's model of a shifting balance between intrapopulation selection, random drift and interpopulation selection, which involves transitions between different stable equilibria.

A central tenet of evolutionary biology has been that gene flow greatly impedes divergence, so that species can only form in geographic isolation[3]. But the existence of sharp, stable clines and hybrid zones in the face of free dispersal shows that gene flow need not destroy spatial divergence. The crucial question is whether reproductive isolation can originate within a continuous population. If a new equilibrium is to be established by random drift, a population must move to this state in some small region. The new state will be separated from the old by a tension zone, and it must, if speciation is to proceed, expand outwards until it covers an area large enough to resist swamping from the outside (Fig. 4*a*). The probability of a shift (per unit time and per unit area) can be calculated using methods adapted from quantum field theory[59,65]. If neighbourhood size is small, and the new equilibrium is more attractive than the old, this probability can be appreciable (Fig. 4*b*). Even if the chance of any one mutation being fixed is small, the net probability summed over a large species range can easily account for observed rates of speciation and chromosomal evolution[66].

Similar arguments apply to shifts in populations subdivided into discrete demes[66]. The dynamics of tension zones is such that sampling drift can cause divergence despite free gene flow. Reproductive isolation, however, can also be caused by geographical or temporal changes in selection in space and time (for example, *Partula*[45]), or by the accumulation of incompatible mutations (for example, *Sorex*[36]; see also ref. 52). These mechanisms may be more important than random drift; unfortunately, it is much harder to distinguish between possible mechanisms of speciation than to find the present nature and effects of species differences.

The abundance of hybrid zones tells us that populations can, and have, shifted between alternative stable combinations of

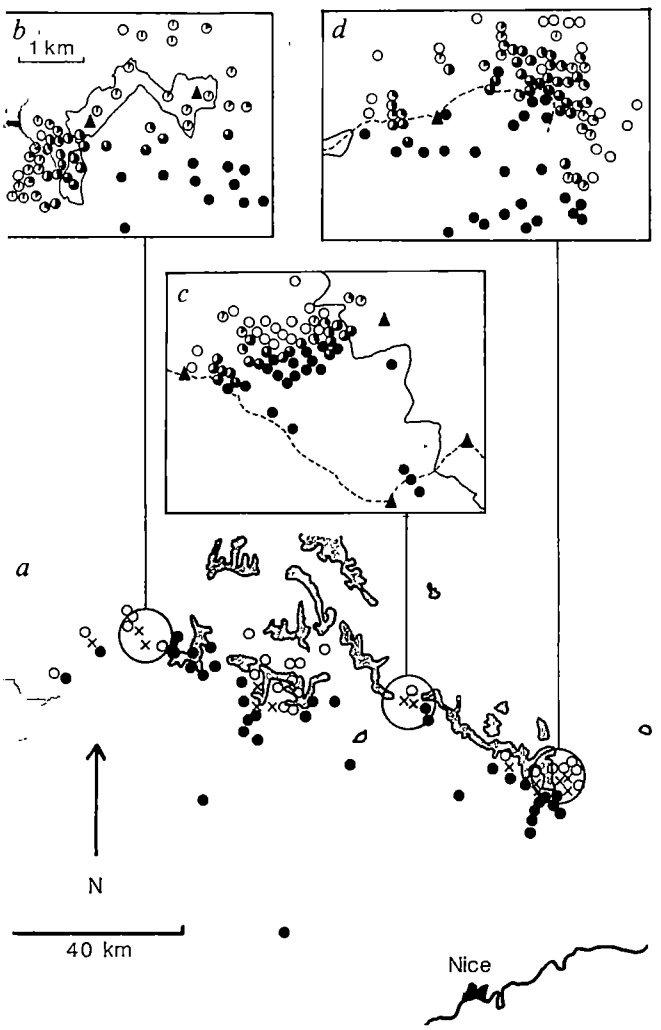

FIG 3 *a*, The tension zone that separates two chromosomal races in the grasshopper *Podisma pedestris* runs near to the main ridge of the Alpes Maritimes. Open circles, samples fixed for the ancestral karyotype, filled circles, samples fixed for a Robertsonian fusion between the *X* chromosome and an autosome; crosses, mixed samples. Shaded areas are higher than 2,500 m. *b–d* Detailed transects show that the zone fluctuates a few kilometres on either side of the main ridge. The solid line shows the 2,500-m contour (except in *b*, where it shows the 1,900-m contour). All insets are to the same scale. The dotted line shows the main ridge, and triangles represent peaks. The pie diagrams show the frequency of the fusion in samples of ~20 males. *b*, Seyne, *c*, Col de la Lombarde, *d*, Vallon de Pontanalbe.

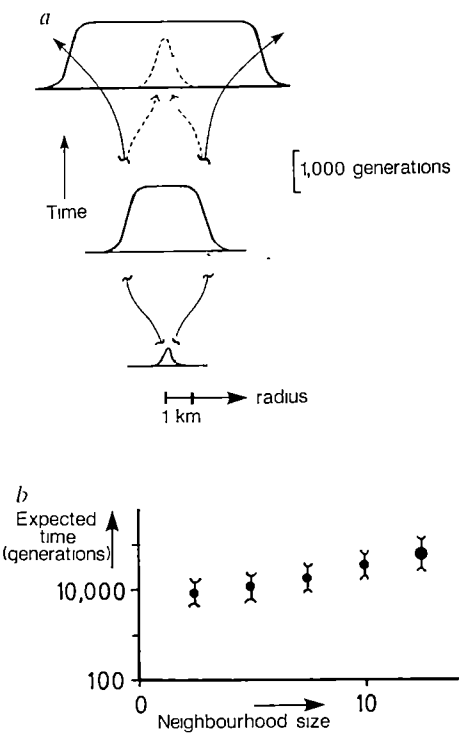

FIG 4 *a*, The establishment of a new adaptive peak in a two-dimensional habitat. Disruptive selection acts on a polygenic character, the new peak gives a mean fitness that is 1.33% greater than that of the old peak, and the two peaks are separated by a fitness trough of depth 1.98%. A chromosome rearrangement with fitnesses 1·0 82 1.04 would follow a similar path. The dispersal rate is $\sigma = 100$ m in a generation. The most probable path for a transition consists of an initial movement out to the unstable equilibrium, taking ~1,000 generations. The population may then fall back to the original equilibrium (dashed line), or the bubble may expand out to cover the entire range, eventually reaching a constant velocity of 3.2 m per generation. The two pairs of curves headed by arrows plot the radius of the bubble against time, (from ref. 65) *b*, A chromosomal rearrangement has an appreciable chance of fixation in a two dimensional habitat, provided that the new homozygote confers a substantial advantage, and that the neighbourhood size is not too large. The graph shows expected time (±2 s.e.m.) before the new karyotype is fixed, plotted against neighbourhood size. Results are from a simulation of 10×10 demes, with $\sigma = 0.45$ deme spacings. Fitnesses are 1.0 94 1.12, and the mutation rate is $\mu = 10^{-5}$.

genes. Wright[6] realized that mass selection would bring a large random-mating population to a nearby equilibrium, but not to the global optimum. This is the central obstacle to any optimization algorithm[67]. Wright argued that evolutionary advance would be most rapid in a population spread over a large area, so that different gene combinations could be tried out in different places. Fitter combinations of genes would be more likely to be established, and would spread at the expense of others. Because selection is between different equilibria, selection could favour traits that are advantageous to the whole population, rather than to individuals. This is a form of 'group selection' that includes a powerful mechanism for generating and maintaining spatial variation, and that does not act in opposition to natural selection. To this extent, Wright's view is more plausible than traditional models for the evolution of altruistic traits[68–70]. Explicit models show that fitter combinations of genes are indeed more likely to be established[71], particularly in a continuous population[65,71]. Although an inferior equilibrium might be reached by chance in a single isolate[71], this can never happen in a broad continuum: the inferior state will be swamped.

It is possible to estimate the relative importance of individual and group selection. To illustrate this, suppose that an increase in homozygote fitness by a factor of $1+2S$ causes the population density to increase by the same factor. Then, the tension zone will advance both because of the asymmetric selection between individuals, and because of the greater flow of genes out of areas containing the superior homozygote and hence having greater density. It is this latter effect which we see as a form of group selection. The rate of advance due to individual selection is $S/2s$ in scaled units, whereas the contribution of group selection is $S/5$, which must be smaller. Similar examples lead to the generalization that individual selection is usually stronger than group selection[72]. A similar conclusion has been reached for a population subdivided into demes, and subject to extinction and recolonization[71].

There are other major obstacles to adaptation through the shifting balance. Equilibria can gain an advantage for arbitrary and non-adaptive reasons: dominant alleles[21] and alleles giving increased dispersal[72] tend to spread. More importantly, gene combinations that happen to coincide with regions of population expansion will gain an undue advantage. For example, the positions of most European hybrid zones are thought to be determined by postglacial expansion from small refugia[2,13]. The gene combinations that happened to be in those refugia will be greatly over-represented. This process is analogous to sampling drift, but acts at a higher level. It will overwhelm any systematic group selection favouring new equilibria, simply because of the small number of independently expanding and contracting regions. A further problem is that tension zones involving one set of characters are usually clumped with zones involving others. Once independent zones are brought together, by co-adaptation or by a common response to population movements, they can only be separated by drastic events. Although tension zones can in principle pass through each other, producing a recombinant population, we know of only one clear example where this has taken place (*Warramaba viatica*; ref. 10) Thus, for the same reasons that selection on small asexual populations, or between whole species, is ineffective, Wright's shifting balance is unlikely to be a major cause of adaptation. Nevertheless, the processes that Wright analysed are essential to divergence and speciation.

Conclusion

It is extremely difficult to estimate selection pressures, rates of gene flow, and gene numbers from laboratory crosses or field manipulations. Studies of hybrid zones that include several markers and enough samples from a continuous transect are a uniquely valuable source of such information[8,20,21,32,33,42]. The few cases that have been surveyed in sufficient detail indicate that reproductive isolation is caused by selection on large numbers of genes, and can pose a substantial barrier to gene exchange. More work is needed to show whether this remains true across a wider range of groups, and to find the precise mechanisms of isolation.

What is the genetic basis of the morphological and behavioural differences between hybridizing taxa? Is the spread of alternative adaptive peaks determined by their selective advantages, or by arbitrary changes in population structure? Does the increased variance in fitness in hybrid zones lead to changes in mating preferences or recombination rates? What is the effect of reduced fitness on the population size? Such questions touch on many controversies in evolutionary biology—hybrid zones provide a ready opportunity for their empirical investigation □

Simian virus 40 large tumour antigen (T) is a replication origin binding protein required for viral DNA synthesis. Unphosphorylated T antigen is deficient in promoting DNA replication *in vitro* but can be activated by phosphorylation at residue threonine 124 by the cdc2 protein kinase. This observation demonstrates that T is regulated by phosphorylation and provides a model for cdc2 function in the control of DNA replication.

THE large tumour antigen (T) of simian virus 40 (SV40) is a multifunctional protein that plays diverse roles in the life cycle of the virus[1]. The T antigen is required for initiation of viral DNA replication during lytic infections of permissive cells[2,3] and also regulates both early and late viral gene transcription[4–7]. T is known to regulate the two initial viral functions by direct interaction with two closely positioned sites (sites 1 and 2) within the SV40 genome[8,9] (see Fig. 3). Binding to site 1 primarily acts to inhibit transcription of T (ref. 10), whereas site 2 is required for viral DNA replication[11–15]. In addition to the DNA-binding properties of T, a variety of other biochemical activities have been associated with the protein, including DNA helicase[16] and origin-specific unwinding activities[17]. T antigen also acts to induce and maintain a transformed phenotype in non-permissive cells[1], possibly by binding to cellular proteins such as p53 (ref. 18) and rb (ref. 19) that may normally act as negative regulators of growth. Only the role of T in viral DNA replication is considered here.

Cell-free lysates have been developed in which T antigen binds to the viral origin and promotes DNA replication[14,20]. In such lysates the replication of SV40, or more generally plasmids carrying the viral replication origin, is absolutely dependent on exogenously added T but otherwise relies entirely on cellular factors. The ability of T to initiate DNA synthesis is influenced by its state of post-translational phosphorylation[21,22]. T is phosphorylated in two regions, located in clusters at the N and C termini of the protein[23]. Both of these lie outside a minimal region of the protein required for DNA binding[24] and may act both to activate or inhibit T-dependent replication[21–28].

We have taken advantage of T purified from *Escherichia coli* that is in an underphosphorylated state and is deficient in directing DNA replication[29], and find that the cdc2 protein kinase, a critical regulator of the cell cycle in eukaryotes, phosphorylates T at threonine residue 124 (Thr 124) with great efficiency *in vitro*. This modification, which occurs *in vivo*[23] alters the DNA-binding pattern of the protein and activates T-dependent SV40 DNA replication. Our observations have implications for the role of cdc2 in the lytic cycle of the virus and possibly for the function of this protein kinase in cellular DNA replication.

Thr 124 phosphorylation

The cdc2 protein kinase is required for the initiation of DNA replication in two species of yeast, *Saccharomyces cerevisiae*[30] and *Schizosaccaromyces pombe*[31], but its S-phase substrates remain unknown. During a search for possible substrates of cdc2 purified from HeLa cells[32] we investigated the possibility that SV40 T antigen, which plays a critical role in viral replication, might be regulated by cdc2. As substrate, we initially used an N-terminal fragment of T (T 259) that retains origin-specific DNA-binding properties[33]. T 259 was expressed in *E. coli* and purified by immunoaffinity chromatography (Fig. 1*a*, left panel). The purified protein was found to be readily phosphorylated by cdc2 (Fig. 1*a*, right panel). We estimate that ~20% of T molecules were modified during a prolonged incubation with the enzyme. Phosphoamino-acid analysis of the phosphorylated T revealed that only threonine residues were modified (Fig. 1*b*).

To map the threonine residue within T 259 phosphorylated by cdc2, the protein was cleaved with proteases (see Fig. 1, legend). The resulting peptides were resolved by gel electrophoresis[34]. A major phosphate labelled band of relative molecular mass (M_r) ~3,500 (3.5K) was detected (Fig. 1*c*). The peptide was eluted from the gel and sequence analysis (see Fig. 1, legend) revealed the following: Asn-Leu-Phe-Cys-Ser-Glu-Glu-Met-Pro-Ser-Ser-Asp-Asp-Glu-Ala-Thr-Ala. Yields of further amino acids were below detectable limits. The first amino acid of this sequence corresponds to Asn 102 (ref. 1). Taking into account the apparent molecular mass of the proteolytic cleavage product and the specificity of trypsin and V8 proteases, we infer that the phosphopeptide spans residues Asn 102–Lys 131. This region contains two threonine residues. Thr 117 and Thr 124, of which Thr 124 is known to be phosphorylated *in vivo*[23]. The region surrounding Thr 124 (His-Ser-Thr*-Pro-Pro-Lys-Lys-Lys-Arg-Lys) bears some similarity to sites within histone H1 that are phosphorylated by the growth-associated, or M-phase specific histone H1 kinase[35]. This enzyme is thought to be the same as that used here[32,36].

To further examine the possibility that Thr 124 is the site of phosphorylation by cdc2, we prepared a mutant at this site by

* Present address: Department of Biochemistry, University of California, Berkeley, California 94720, USA

oligonucleotide mutagenesis[37,38] and expressed the altered protein (T 259-Ala 124) in *E. coli*. The mutant protein was purified and found to be phosphorylated at least 200-fold less efficiently by cdc2 than is the wild-type protein (data not shown, but see Fig. 2). Taken together, these data demonstrate that Thr 124 is the site at which cdc2 phosphorylates T 259.

To stringently test whether the phosphorylation of T 259 by the HeLa cell preparation containing cdc2 was in fact due to this enzyme, T 259 kinase activity was assessed in every fraction of the final column (Mono-S) used to purify the cdc2. The profile of T 259 phosphorylation was compared with phosphorylation of histone H1, a known substrate of the enzyme[32,36]. The elution profiles of T 259 and histone-H1 kinases overlapped closely (Fig. 2). Even with addition of equimolar amounts of protein, histone was more heavily phosphorylated than T 259 (it should be noted that histone contains multiple sites of cdc2 phosphorylation[35]). Also, histone effectively competed for phosphorylation of the endogenous cyclin subunit of the kinase, p62 (see ref. 32), whereas T 259 did not (Fig. 2*a*). No column fraction phosphorylated the mutant T 259-Ala124 protein to an appreciable extent (Fig. 2).

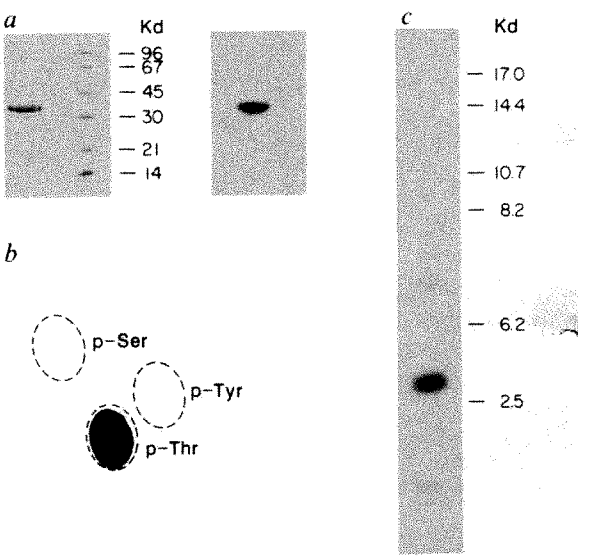
Origin binding

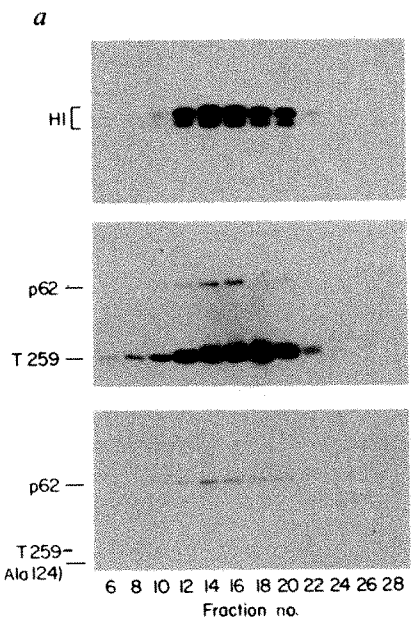
The effect of phosphorylation by cdc2 on the DNA-binding properties of T 259 was examined using a modified McKay assay[33,39]. In this assay an equimolar mixture of end-labelled DNA fragments containing either site 1, site 2, or the wild-type origin containing both sites 1 and 2 was incubated with T antigen. A monoclonal antibody (Pab419)[40] was used to precipitate T and any DNA fragment to which it may be bound. The labelled DNA was visualized by autoradiography (see legend to Fig. 3).

Unphosphorylated T 259 purified from *E. coli* has the highest affinity for the wild-type fragment and binds preferentially to site 1 rather than site 2 (see refs 24, 33 and Fig. 3). Phosphorylation of T 259 by cdc2 strongly stimulated the ability of the protein to bind to the wild-type DNA fragment and reversed the order of preference of the unphosphorylated protein for binding. Quantitation of this effect by scintillation counting of excised gel bands revealed that phosphorylation of T 259 caused a twenty-fold increase in binding to the wild-type DNA and site 2-containing DNA fragment. Little, if any, effect on site 1 binding was observed.

To test whether these effects were a consequence of phosphorylation at Thr 124, the mutant protein (T 259-Ala 124) was exposed to cdc2 under standard phosphorylation conditions. The mutant protein binds to site 1 and the wild-type origin bearing DNA fragments with efficiency comparable to the native T 259, but its DNA-binding activity was unaffected by exposure to cdc2 (Fig. 3). This confirms that the altered properties of the wild-type T 259 following exposure to cdc2 is due to phosphorylation at Thr 124. The DNA-binding pattern of bacterial-derived T 259 that has been phosphorylated by cdc2 was indistinguishable from that of the same protein purified from mammalian cells[24,33], displaying a marked preference for binding to site 2 (within the core origin) compared to site 1 (within the transcriptional autoregulatory region).

In a further test, we investigated the effect of phosphorylating full-length T (T 708) with cdc2. Like T 259, T 708 purified from *E. coli* binds efficiently to site 1, but poorly to site 2 (ref. 29 and Fig. 4). After exposure of bacterial-derived T 708 to cdc2, site-2 binding was stimulated at least 10-fold (Fig. 4). Again this property mimics that of T 708 purified from mammalian cells rather than *E. coli* (Fig. 4). Exposure of mammalian T 708 to cdc2 resulted in no further stimulation of its site-2 DNA-binding





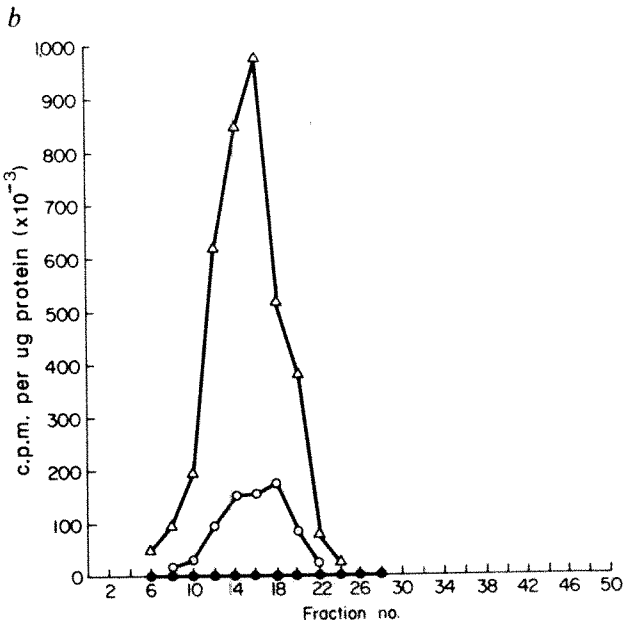


FIG. 1 Phosphorylation and phosphoamino-acid analysis of T 259. *a*, Left panel, Coomassie blue staining of immunoaffinity-purified T 259. Right panel, autoradiogram of T 259 phosphorylated by cdc2. *b*, 2-D-phosphoamino-acid analysis of T 259 phosphorylated by cdc2. *c*, Proteolytic cleavage fragment phosphorylated by cdc2.

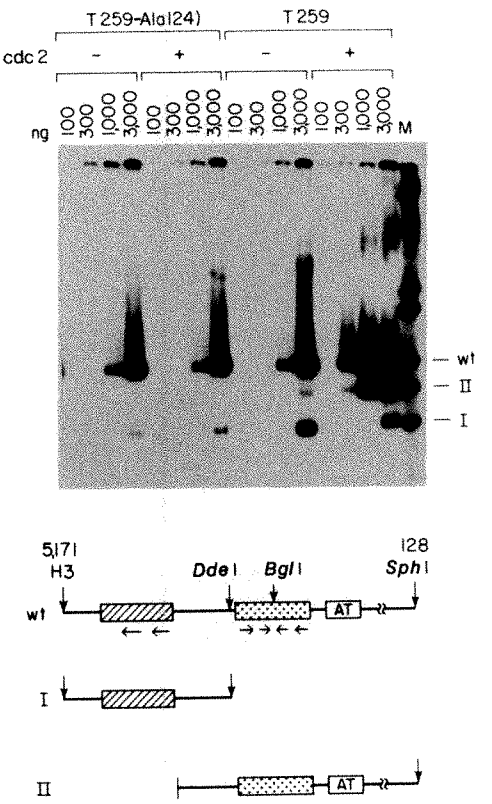

METHODS. The N-terminal 259 amino acids of SV40 large T antigen containing an extra 3 amino acids at the C-terminal end of the molecule was expressed and purified from *E. coli*[33]. cdc2 protein kinase was purified as described previously[32]. T 259 (10 μg) incubated with 1–5 μl cdc2 for 60 min at 30 °C in 50 μl of 50 mM Tris-HCl pH 8.0, 10 mM $MgCl_2$, 1 mM DTT, 50 μM ATP and 50 μCi [γ-^{32}P]ATP (3,000 Ci mmol^{-1} (NEN). A fraction of the reaction was separated in SDS-PAGE[52] (10% acrylamide gel). The gel was stained with Coomassie blue and exposed for autoradiography. For the phosphoamino-acid analysis, half of a kinase reaction was precipitated with trichloroacetic acid and the protein was hydrolysed by HCl vapour, under N_2 atmosphere, at 105 °C for 90 min (according to PICO-TAG instructions). The hydrolysed amino-acids were resuspended in 10 μl of water containing 7 mg ml^{-1} cold phosphoamino-acid standards and 2 μl were electrophoresed in two dimensions on TLC plates (250 μm Whatman K2 cellulose). The migration of unlabelled standards was determined by ninhydrin staining and labelled amino acids were detected by autoradiography. For proteolytic cleavage of phosphorylated T, analytical digests were performed on 1 μl of the phosphorylation reaction mixture. Preparative digestion was performed on 120 μl, reduced to 10 μl in a vacuum centrifuge (Savant). Samples were redissolved in 8 M urea, 0.4 M ammonium bicarbonate, and 4.5 mM dithiothreitol (DTT), and incubated at 50 °C for 15 min. Iodoacetic acid (5 mM) was added and alkylation was allowed to occur for 15 min at 37 °C. The reaction was terminated with an additional aliquot of dithiothreitol. The samples were diluted with a three-fold excess of water, resulting in a solution that was 2 M urea, 0.1 M ammonium bicarbonate. An aliquot (2 μl for analytical, 5 μl for preparative) of trypsin (EC 3.4.21.4; TPCK-treated, Worthington; 1 mg ml^{-1} in 1 mM HCl) was added, and the digestion allowed to proceed for 12 h at 37 °C. A second aliquot was added, and the reaction incubated for an additional 12 h. Digestion with *S. aureus* (strain V8) protease (EC 3.4.21.19; Worthington; 1 mg ml^{-1} in 0.1 M ammonium bicarbonate) was done as with trypsin. The preparative digest received three aliquots of protease over 24 h. Proteolytic digests were subject to electrophoresis on 16% (w:v) acrylamide gels in the presence of SDS and urea, using the Tris-tricine buffer system[34]. Analytical digests were run on 1.0-mm thick gels, and preparative digests on 0.75-mm thick gels. After electrophoresis, the gels were stained with Coomassie brilliant blue and exposed to autoradiography. On the preparative gels, the portions of the gel corresponding to the visible spots on the film (see panel *c*) were excised, and eluted overnight in buffer containing 6 M urea, 0.2 M ammonium bicarbonate, 0.1% (w:v) SDS. The eluate was dialysed using 1,000 nominal molecular mass cutoff membrane on a microdialysis apparatus (Pierce), and the sample was reduced in volume to near dryness in a vacuum centrifuge. The sample was suspended in 50 μl water and precipitated with 9 volumes of acetone for 60 h at −20 °C, and collected by centrifugation. The resulting pellet was redissolved in 0.1% trifluoroacetic acid, and subject to HPLC on a C_8 silica (300 pore size) column (2.1 × 50 mm, Applied Biosystems) using a Hewlett Packard 1090M chromatograph. The optical absorbance of the effluent was monitored at 214 nm. Peaks containing radioactivity were analysed by automated sequencing on an Applied Biosystems 470A instrument, in which 45% of the sample was injected on-line to an Applied Biosystems 120A Analyser.

IG. 2 Comparison of istone H1 and T-antigen inase activities in fractions f a Mono S column. *a*, ssay of the kinase activity oss the column using ither histone H1 (top), 259 (centre) or T 259–la 124 (bottom) as sub- strate. p62 is the ndogenous cyclin-B sub- strate of the kinase. *b*, Quantitation of the labelling f histone H1 (triangle), 259 (open circle) or 259–Ala 124 (closed circles) in the kinase assays.

METHODS. Highly purified cdc2 kinase obtained from HeLa cells as described[32] was rechromatographed using a Mono S 5/5 column (Pharmacia). Fractions from the column were assayed for kinase activity using 1 μg of either calf thymus istone H1 (Boehringer), T 259 or T 259–Ala 124. The mutant was obtained by oligonucleotide directed mutagenesis[37,38] of T 259 to create a single amino-acid substitution consisting in a change of Thr 124 to Ala 124. The kinase reactions were carried out for 10 min at 30 °C in the following buffer conditions: 50 mM Tris-HCl pH 8.0, 10 mM $MgCl_2$, 1 mM DTT and 5 μM ATP and 10 μCi [γ-^{32}P]ATP. The reactions were terminated by the addition of electrophoresis sample buffer. A fraction of the stopped reactions were then fractionated on SDS-PAGE followed by Coomassie blue staining of the gels and autoradiography. Alternatively, the sample was precipitated with trichloroacetic acid (TCA) and acid insoluable counts were determined by autoradiography.

IG. 3 DNA-binding properties of T 259 and T 259–Ala 124 exposed to cdc2. op, indicated amounts of T, exposed (+) or unexposed (−) to cdc2 were ncubated with an equi-molar mixture of end-labelled fragments shown in he marker lane (M). Protein–DNA complexes were precipitated with Pab419 nd the bound DNA was analysed by SDS-PAGE. The migration positions of agments bearing wild-type (wt), site 2 alone (II) or site 1 alone (I) are ndicated. Bottom, maps of the DNA templates containing either site I, site or the wild-type origin from SV40 used in the origin binding assays. The oxes represent the individual sites and the horizontal arrows represent he pentanucleotide recognition sites of T. Vertical arrows demark cleavage ites for restriction endonucleases.

METHODS. Parallel samples containing 6 μg of immunoaffinity purified T 259 r T 259–Ala 124 were preincubated in 10 μl of kinase buffer (50 mM ris-HCl, pH 8, 10 mM $MgCl_2$, 1 mM DTT) containing 75 μM ATP at 30 °C for 3 min. To half of the samples 1 μl cdc2 kinase was added and the reactions were incubated at 30 °C. After 1 h the reactions were placed on ice. Each titration point of T was brought to a final volume of 30 μl with kinase buffer containing 75 μM ATP. An equimolar mixture of DNA preparations carrying site I (pOS-1; SV40 nucleotides (nt) 5,171–5,228), site II (pSVOd13; SV40 nt 5,209–128) and wild-type origin (pSVO$^+$; SV40 nt, 5,171–128)[15,33] were digested with *Tac*I. The mixture was end-labelled with the large fragment of DNA polymerase I (Klenow) in the presence or radiolabelled deoxynucleotides, extracted with phenol and chloroform, and ethanol precipitated. This mixture (50 ng) in 30 μl of 2× origin binding buffer (20 mM HEPES, pH 7.4, 200 mM KCl, 2 mM $MgCl_2$, 10% glycerol, 100 μg μl^{-1} BSA) was added to each 30 μl titration point of T (described above) and incubated on ice for 1 h. Anti-T monoclonal antibody (7.5 μg) (Pab 419) (ref. 40) in 5 μl of 1× origin binding buffer was added and allowed to incubate for a further hour. Protein A Sepharose slurry (10% (v/v), 100 μl in NET buffer (50 mM Tris-HCl, pH 7.4, 150 mM NaCl, 5 mM EDTA, 0.05% NP40) was then added and the reactions were incubated on a rocker for 50 min at 4 °C. The beads were pelleted, washed three times with 1 ml of NET buffer, resuspended in 1% SDS, 25 mM EDTA, incubated at 65 °C for 15 min and electrophoresed on a 6% native polyacrylamide gel. Gels were exposed to Kodak XAR film.

properties (Fig. 4, note that the mammalian T 708 used in this udy was purified from HeLa cells infected with an adenovirus construct carrying T 708, ref. 21).

DNA synthesis

Full-length T antigen purified from *E. coli* was used to investigate he effect of protein phosphorylation on the ability of T antigen to initiate SV40 DNA synthesis. Underphosphorylated T from bacteria replicates SV40 DNA *in vitro* to only 10-15% of the level of replication directed by T antigen purified from HeLa cells[29]. To assess the effect of cdc2 phosphorylation on the ability of T to initiate SV40 DNA synthesis it was first necessary to establish conditions for the kinase reaction that were compatible with subsequent assay of *in vitro* DNA replication[14,20]. This was

essential because the ATP required as a source of phosphate in the kinase reaction acted as a potent inhibitor of subsequent DNA synthesis (data not shown). This may be due to ATP-dependent formation of higher order aggregates of T antigen[41,42]. Using mammalian T 708 in test experiments, the inhibitory effect of ATP was overcome if the mock kinase reaction was performed in the presence of origin-containing template DNA. Levels of DNA replication obtained following preincubation in the presence of both ATP and DNA template, were similar thereafter to those directed by identical amounts of T 708 maintained on ice in the absence of ATP (data not shown). For this reason, in all further experiments the kinase reactions were performed in the presence of template DNA.

As described previously[14,20], T 708 purified from HeLa cells is highly active in directing DNA replication *in vitro*, whereas that from *E. coli* is relatively weak[29] (Fig. 5). Exposure of *E. coli*-derived T 708 to the Mono-S peak fraction of cdc2 kinase stimulated the ability of the protein to initiate SV40 DNA synthesis *in vitro* (Fig. 5). This effect was abolished if the kinase preparation was briefly boiled before being incubated with T, or if the template DNA did not contain the SV40 replication origin (Fig. 5). No further enhancement of DNA replication was observed if HeLa cell purified T 708 was exposed to cdc2 *in vitro* (data not shown).

Discussion

The primary observation of this report is that phosphorylation of SV40 T antigen at Thr 124 by the cdc2 protein kinase increases the capacity of the protein to bind to the viral origin of replication and further to initiate DNA replication *in vitro*. Previous studies have shown that Thr 124 is phosphorylated *in vivo*[23] and that the integrity of this residue is essential for origin binding and DNA replication[27,28]. No protein kinase capable of phosphorylating this site has previously been identified. Indeed, the present experiments provide the first direct demonstration that phosphorylation at Thr 124 modulates the sequence-specific DNA binding and replication activities of T.

Bacterial-derived T antigen has similar properties to mammalian protein that contains a single lesion at Thr 124 (refs. 27, 29). Neither polypeptide binds efficiently to site 2 of the viral origin. It is interesting, however, that the bacterial protein displays a weak ability to drive DNA replication, whereas the T-Ala 124 mutant protein purified from mammalian cells does not (I.M. and E. Fanning, unpublished results). It is possible

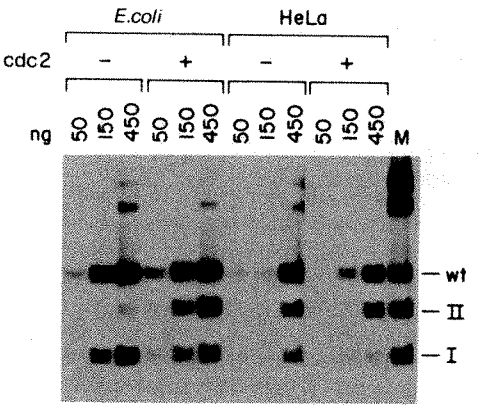

FIG. 4 DNA-binding properties of full length T 708 purified from either *E. coli* or human HeLa cells. Protein was either exposed to cdc2 (+) or not (−), before being assessed for DNA binding.
METHODS. Parallel sets of reactions containing 50, 150 and 450 ng of immunoaffinity purified *E. coli* and HeLa derived full length Tag (see fig. 5) in 20 μl of 30 mM HEPES–KOH pH 7.4, 7 mM $MgCl_2$, 0.5 mM DTT containing 500 μM ATP were assembled on ice. To one set of reactions an aliquot of highly purified cdc2 was added. All reactions were immediately incubated at 26 °C for 25 min. The reactions were removed and placed on ice. An equi-molar mixture (50 ng) of site I, II and wild-type origin-bearing fragments (Fig. 3) in 30 μl of 1× origin binding buffer (Fig. 3) was added to each tube. After incubating on ice for 50 min 5 μl of 1 μg ml^{-1}, Pab 419 (ref. 40) in 1× origin binding buffer was placed in each reaction. A 50 min incubation on ice followed. The remainder of the experiment is as described in Fig. 3.

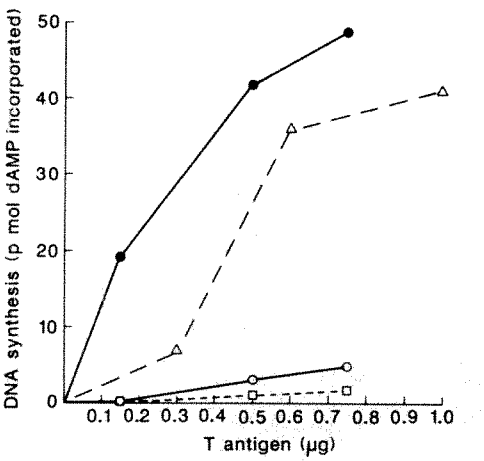

FIG. 5 Activation of T-dependent DNA replication by cdc2. DNA synthesis, assessed by incorporation of dAMP into origin-containing template DNA, was driven by indicated amounts of input T 708 from different sources. Bacterial T phosphorylated by cdc2 (closed circles), HeLa cell T (triangles), bacterial T exposed to boiled cdc2 (open circles), bacterial T exposed to native cdc2 (squares), but using template DNA lacking a viral replication origin.
METHODS. Full length T antigen from *E. coli* was purified by a modification of a published procedure (ref. 29). The high speed supernatant described was brought to 30% saturation with solid $(NH_4)_2SO_4$. The supernatant from this precipitation step was then brought to 55% saturation with solid $(NH_4)_2SO_4$. The 30–55% precipitate was then dissolved and dialysed against 1 litre of 50 mM Tris-HCl, pH 7.4, 150 mM NaCl, 1 mM EDTA, 10% glycerol (2 changes of buffer, 500 mls, each for 1 hour). This fraction was then applied to an imunoaffinity column containing immobilized Pab 149 (ref. 40) as described previously[21]. The neutralized eluate containing peak fractions from this column were then loaded onto a 100 μl double strand DNA cellulose column (Sigma) equilibrated in 20 mM HEPES-KOH, pH 7.4, 5% glycerol. Unbound material was removed by washing the column in this same buffer. The column was then washed with 20 mM HEPES-KOH, pH 7.4, 50 mM NaCl, 5% glycerol. T antigen was eluted im 20 mM HEPES-KOH, pH 7.4, 400 mM NaCl, 5% glycerol. Peak fractions were pooled, dialysed overnight against 20 mM HEPES-KOH, pH 7.4, 5 mM NaCl, 0.1 mM EDTA, 1 mM DTT, 10% glycerol, snap frozen in a dry ice-ethanol bath and stored at −70 °C until use. All kinase reactions and DNA synthesis reactions were assembled on ice. 1 μl of cdc2 kinase (mono S fraction) was added to reaction vessels containing various amounts of purified T antigen and 300 ng of either wild type plasmid or 8–4 DNA (ref. 12) in 30 mM HEPES, pH 7.4, 7 mM $MgCl_2$, 0.5 mM DTT, 0.5 mM ATP. The final reaction volume was 20 μl. Kinase reactions were incubated at 26 °C for 25 minutes. The reactions were placed on ice whereupon they received a 30 μl aliquot containing a cytosolic fraction from human 293 cells (S100), with the additional reagents necessary for SV40 DNA synthesis[14,20]. After 2.5 hours at 37 °C, the products of the reaction were precipitated with trichloroacetic acid and collected by filtration onto glass fibre filters. The amount of acid insoluble radioactivity was quantitated by counting the dried filters in liquid scintillant.

that the wild-type bacterial protein becomes partially phosphorylated on Thr 124 during incubation in the cell-free lysate. Lysates prepared in a similar way to those used in this study, a crude S100 fraction of human 293 cells (Fig. 5, legend), contain cdc2 detectable by immunoblotting (B. Stillman, personal comm.).

It is striking that bacterial T 708 that has been modified by cdc2 *in vitro* is more active in DNA replication than the HeLa cell protein. Previous studies of T phosphorylation have identified an inhibitory class of serine phosphorylation sites[21,22,26]. Exposure of T to calf intestinal alkaline phosphatase (CIAP), which dephosphorylates phosphorserine but not phosphothreonine, activates the ability of the protein to bind the origin and replicate DNA. This observation may also be related to the purification of type 2A phosphatase as a replication activating protein in T-dependent cell lysates[43]. The cdc2 phosphorylated *E. coli* T 708 may resemble T antigen from mammalian cells which has been treated with CIAP or type 2A phosphatase.

It is of particular interest that cdc2 is able to phosphorylate T at the critical residue of Thr 124. In fission yeast, cdc2 function is essential both for the initiation of DNA replication and also, in association with the *cdc*13-encoded cyclin[44], for the entry in mitosis[31]. Much evidence supports the idea that in vertebrate cells the protein kinase also plays an essential role in regulating mitosis[45–48] but the present experiments provide the first indication that cdc2 might also act in the initiation of DNA replication, albeit in a viral model.

In considering the physiological significance of our results the source of the cdc2 kinase should be considered. The enzyme used in the present study consists of cdc2 (p34) and cyclin B (p62) subunits and was purified in a mitotically activated state from cells arrested in M phase with nocodazol[32]. This enzyme is thought to represent the M-phase inducing factor (MPF), that drives an interphase cell into mitosis[36] and yet in the present experiments it is being used to promote T-dependent DNA replication.

It is possible that T becomes phosphorylated on residue Thr 124 by cdc2 during mitosis, but the available evidence indicates that passage of the host cell through M phase is not essential for viral replication. For example, CV1 cells that have been synchronized by mitotic shake-off can be infected with SV40 in the presence of hydroxyurea, which prevents DNA replication. Upon removal of the drug, viral replication proceeds at approximately the same time as cellular replication[49]. In this situation, T would not have encountered a mitotic form of cdc2 in the interval between infection and DNA replication, unless one property of the virus is to inappropriately induce the M phase form of cdc2. It is conceivable that this occurs and that cells fail to enter mitosis prematurely because cdc2 is diverted from its normal mitotic role into the phosphorylation of newly-synthesized T, which instead drives viral DNA replication.

Alternatively, the form of cdc2 used in the present study may not be that responsible for the phosphorylation of T at Thr 124 *in vivo*. The cdc2 molecule associates with proteins other than cyclin B. A complex between cdc2 and a polypeptide with M_r ~60K (p60) has been described in HeLa cells[50]. The identity of p60 is presently unknown, except that the same protein is found in association with E1A in adenovirus-infected cells. From the present perspective, the critical feature of the p60/cdc2 enzyme is that it phosphorylates histone-H1 *in vitro*, but is maximally active during interphase, whereas the cdc2/cyclin B enzyme used here is most active during mitosis[45,50]. It is possible that p60/cdc2, or even cdc2 associated with other regulatory polypeptides, might be primarily responsible for the phosphorylation of T on residue Thr 124 at the initiation of viral replication.

SV40 encodes a T protein which requires phosphorylation on Thr 124 to initiate viral DNA synthesis. This phosphorylation event may represent a mechanism by which the virus senses the state of the cellular replication apparatus. Regulation of T by such a mechanism would prevent abortive initiation and premature template unwinding. The replication machinery in quiescent cells is dormant, thus preventing viral DNA synthesis even if active T was present. In this scheme, T produced at early times after infection is not phosphorylated at Thr 124 and could not initiate viral DNA replication. It does, however, stimulate cellular DNA synthesis[49]. An induced S-phase kinase (containing cdc2) could then phosphorylate Thr 124 and serve as a positive molecular switch by activating viral replication. Consistent with this hypothesis, a form of T which binds site-I DNA has been detected 8 h before a site-II binding form in productively infected cells[51].

The present experiments provide no direct information about a possible role for cdc2 in the initiation of cellular DNA replication. A protein or complex of cellular proteins, however, must perform the origin binding role that T serves in viral DNA replication. The phosphorylation and activation of such replication elements by cdc2 might be a critical step in the initiation of cellular DNA syntheisis. □

The patterning of cells in insect segments requires the exchange of information between cells, which in *Drosophila* depends on the activity of members of the segment-polarity class of genes. Here we report the molecular characterization of one such gene, *patched*. We find that *patched* encodes a large protein with several possible membrane-spanning domains and is expressed in a complex pattern during embryogenesis.

DURING the earliest stages of *Drosophila* embryogenesis a series of positional cues are established along the antero-posterior axis of the embryo (reviewed in refs 1-3). These cues, which correspond to the expression domains of the pair-rule genes, allocate the newly forming cells to individual parasegmental primordia[4,5]. Although much is now known about the intracellular signals that establish the pair-rule gene-expression domains[3], the way in which the information that they encode is transformed to give the detailed pattern of each larval body segment remains poorly understood.

Generation of the segment patterns depends on the activity of the segment-polarity class of genes[6], mutations of which cause locus-specific deletions of different parts of each segment, accompanied by the duplication of the remaining structures. In the absence of expression of the *patched* (*ptc*) gene[6] the middle region of each segment is deleted (Fig. 1); by contrast, mutations at several other loci cause the deletion of the posterior part of each segment. Several of these latter genes have been cloned, and two, *engrailed* (*en*)[7,8] and *gooseberry* (*gsb*)[9,10] have been found to encode homoeodomain-containing proteins. Both of these genes, together with a third member of the class, *wingless* (*wg*)[11], are expressed in specific domains in each parasegment during most of embryogenesis[8-12]; these patterns of expression are first established as the blastoderm cellularizes in response to different combinations and levels of pair-rule gene activity[4,13-15]. These early defined domains mark the boundaries of the parasegmental primordia and can be regarded as providing the reference points for the subsequent elaboration of positional information in each parasegment.

In contrast to the positional signalling that occurs before cellularization, patterning in parasegments seems to involve signalling between cells during the proliferative phase which follows cellularization. The best evidence for this comes from studies of the segment polarity genes themselves. The continued expression of *en*, for instance, requires the expression of *wg* in neighbouring cells[16,17], implying that *wg* is involved in the production of a stimulatory signal that is transmitted to the *en*-expressing cells[16,17]. This interpretation is strongly supported by the extra-cellular distribution of the *wg*-encoded protein[18] and is consistent with the known properties of the growth-factor-like product of the mouse proto-oncogene *int-1*, to which *wg* is closely related[19].

Whereas in normal embryos only those cells posterior to each *wg*-expression domain initiate and maintain *en* expression, in *ptc* mutant embryos, *en* expression is additionally induced in cells anterior to each *wg*-expression domain[16,17]. This indicates that one of the normal functions of the *ptc* gene is to determine the competence of cells to respond to the *wg* signal and hence maintain the appropriate polarity of each parasegment. To investigate the molecular basis of this phenomenon, we have cloned the *ptc* gene. Here we describe its pattern of expression during embryogenesis and show that it encodes an integral membrane protein with multiple transmembrane domains, a structure which is characteristic of several proteins, including membrane-associated receptors.

Molecular cloning of *patched*

To clone the *ptc* gene we induced new alleles of the locus by hybrid dysgenesis and isolated recombinant phage with P-element homology from a genomic library constructed from one such allele. By using fragments from this clone as probes, we cloned and mapped 40 kilobases (kb) of contiguous wild-type DNA (see Fig. 2*a* legend for details). Transcriptional analyses of the region showed that it contains a single transcription unit extending over ~17 kb and encodes a transcript of ~5.8 kb which is expressed during most of embryogenesis (data not

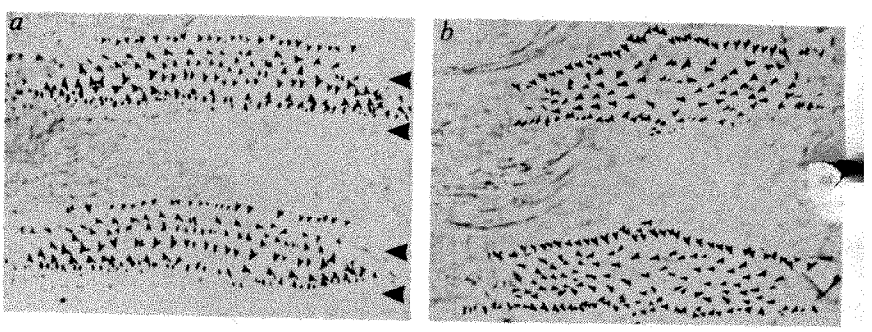

FIG. 1 *a*, Ventral cuticle of the fourth and fifth abdominal segments of a wild-type first-instar larva. Note the distinctive pattern of denticles, each row being composed of elements of characteristic size and polarity. The arrowheads indicate the region of the segmental pattern deleted in *ptc* mutants. *b*, The equivalent region of a larva homozygous for a deficiency of the patched gene ptc^{G12}. In contrast to that in wild-type larvae, the denticle belt is mirror symmetric, the posterior part of each denticle belt being replaced by an anterior part with reverse orientation.

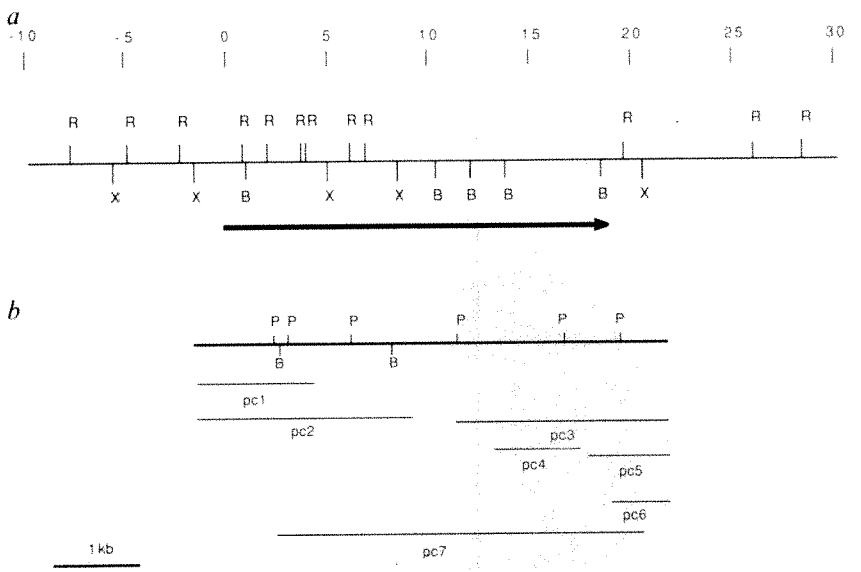

FIG. 2 *a*, Restriction map of the genomic DNA corresponding to the *ptc* gene. The solid line indicates the transcribed region; position 0 is the approximate location of transcription initiation. *b*, Restriction map of the cDNA clones corresponding to the *ptc* transcription unit. *B*, *Bam*HI; *R*, *Eco*R1; *P*, *Pvu*II; X, Xho1.

METHODS. Eight new *ptc* alleles were isolated from among 250,000 flies after hybrid dysgenesis. By *in situ* hybridization, four of these were found to be associated with P-element insertions at the region 44D3, 4 on the right arm of chromosome 2 in the cytological region to which *ptc* had been mapped[40]. One of these alleles, ptc^{P78}, was recombined onto a P-element-free second chromosome, and DNA from these flies was extracted, partially digested with *Mbo*I and cloned into the λ-phage vector EMBL-4 (Stratagene). Recombinant phage with P-element homology were isolated by plaque hybridization and clones deriving from the 44D3, 4 region were identified by *in situ* hybridization to P-element-free polytene chromosomes. By using the genomic sequences flanking the P-element insert as probes, we isolated 40 kb of contiguous DNA from wild-type genomic libraries. Comparison of the wild-type map with that of the mutant clone shows the mutant clone has a deletion of ~15 kb of wild-type sequences, together with an insertion of a P element (not shown). To confirm that the ptc^{P78} allele is indeed associated with this deletion, DNA from flies heterozygous for the mutation was digested with *Eco*RI and probed with fragments that include the deletion breakpoints. Novel bands are seen with both probes, consistent with the deleted structure predicted from the clone. Southern transfer analysis of 16 other *ptc* mutations showed that 8 of them have alterations in the restriction map of the cloned region (I.G., A.H., Y.N., R. Phillips and P.W.I., manuscript in preparation). To identify transcribed regions of the cloned DNA, asymmetric ^{35}S-labelled RNA probes were prepared by *in vitro* transcription of each of the *Eco*R1 fragments (subcloned in Bluescript vector) and hybridized to sections of 0–20-hour-old embryos. This analysis identified sequences within a region from position −2.5 to +20 that were transcribed both in the same direction and with identical spatial and temporal patterns during embryogenesis. Restriction fragments from each end of the transcribed region were used to screen an embryonic cDNA library[7] and two sets of overlapping clones were isolated. Single-stranded probes prepared from the two longest non-overlapping clones (pc2 and pc3) were hybridized to northern-transfer filters of staged total RNA. Both probes detect a single transcript of ~5.8 kb with an identical expression profile; this transcript is most abundant in 6–12-h embryos but is present also in post-embryonic stages (data not shown). Clone pc7 was isolated by R. Phillips (personal communication) from a library constructed by N. Brown (unpublished results).

shown). Several complementary DNA clones derived from this transcription unit were isolated (Fig. 2*b*) and used to prepare probes for analysis by *in situ* hybridization.

Embryonic transcription pattern of *patched*

The pattern of expression of *ptc* is considerably more complex and dynamic than that of *en* (ref. 8), *gsb* (refs 9, 10) or *wg* (ref. 11). In contrast to *en*, *gsb* or *wg* transcripts, when *ptc* transcripts are first expressed in the stage-5 (cellularizing blastoderm) embryo, they are almost uniformly distributed around the periphery of the embryo (compare Fig. 3*a* and *b*). As gastrulation begins, a modulation of *ptc* transcript expression becomes apparent, and by stage 10 (when the germ band is fully extended), the transcript is expressed in broad bands in both the ectoderm and mesoderm of each parasegment, in contrast to the narrow stripes typical of the expression domains of *en* and *wg* at the same stage (Fig. 3*c*, *d*; Fig. 4). Comparison of adjacent sections of the same embryo hybridized with different probes shows that at this stage the *ptc* expression domain is complementary to that of *en* and overlaps that of *wg* (Fig. 4). In the mesoderm, expression is out of register with the overlying ectoderm, so that cells that still express *en* also express *ptc* (Fig. 4).

In stage 12 embryos, before the onset of germ-band shortening, a further restriction occurs in the ectodermal domains; the *ptc* transcripts disappear from the central region of each domain so that there are two narrow stripes of *ptc* expression in each segment, one marking the anterior boundary of each segment and the other overlapping the *wg*-expressing cells (Fig. 3*e–h*). This pattern of expression persists until the end of embryogenesis.

Predicted protein structure

The entire coding sequence of the *ptc* transcription unit was determined by dideoxy sequencing[20] of the cDNA clones. Sequence analysis of genomic subclones has revealed a consensus transcription initiation site and a possible TATA-sequence box just upstream of the 5′ end of the pc2 cDNA clone (Y.N., unpublished observations), indicating that this represents the 5′ terminus of the *ptc* messenger RNA.

By aligning the sequences of several overlapping cDNAs, we defined a contiguous stretch of 5547 nucleotides between the 5′ end of pc2 and the 3′ end of pc3, which agrees well with the size (~5, 8 kb) of the *ptc* transcript determined by northern-blot analysis (I.G., unpublished data). Conceptual translation of the complete cDNA sequence in all three reading frames reveals a single long open-reading-frame (ORF) of 3,897 nucleotides, preceded by a long 5′ untranslated leader sequence of ~750 nucleotides. The context of the initiation codon AAC-CATAATGGAC (Fig. 5) shows a reasonable similarity to the consensus insect translational initiation sequence[21]. Downstream of the translation termination codon is an untranslated region of ~890 nucleotides. This region includes two potential polyadenylation signals having the canonical sequence AATAAA (ref. 22; Fig. 5). A third, atypical sequence, ATATAA, which could also function, albeit inefficiently, as a polyadenylation signal (N. Proudfoot, personal communication), is located 21 nucleotides from the 3′ end of the pc7 clone. The 3′ untranslated region is also characterized by five pentanucleotide repeats that have the sequence ATTTA (Fig. 5). These repeats are found in the 3′ trailers of several genes including c-*fos* (ref. 23) and lymphokine granulocyte-macrophage colony-stimulating factor (GM-CSF)[24], where they confer message instability. We have not determined the complete intron–exon structure of the *ptc* gene, but comparison of the cDNA and genomic maps indicates a large 5′ intron of at least 8 kb and several smaller introns at the 3′ end of the transcription unit (data not shown).

The large ORF is capable of encoding a 1,299-amino-acid protein of predicted relative molecular mass (M_r) 144,000.

Hydropathy analysis[25] of the amino-acid sequence enabled us to predict the presence of seven main hydrophobic stretches, but no signal peptide sequence (Fig. 6). The lengths of three of these (*A*, *B* and *E*) are consistent with their spanning the membrane once, whereas regions *C*, *D*, *F* and *G* are large enough to cross the membrane twice or even three times.

By considering the distribution of charged residues around and in these hydrophobic blocks, we have tentatively designated ten distinct transmembrane domains to the *ptc* gene product (Figs 5 and 6); two of these domains are long enough to cross the membrane twice, and hence enter and leave the membrane on the same side, in a manner analogous to that suggested for domain A of the CD20 antigen protein[26]. The orientation of the Ptc protein relative to the membrane is based partly on the preferential location of clusters of positively charged residues on the inside of the membrane, but principally on maximizing the number of possible glycosylation sites located extracellularly. Of the eight possible glycosylation sites, six are located in the two large internal hydrophilic regions, which are accordingly positioned extracellularly in our model (Fig. 6). This configuration places both the amino terminus and carboxyl terminus (which also contains two possible glycosylation sites inside the cell, but other models, which position the C-terminus outside the cell, are also possible (not shown). The C-termina region is highly charged and is characterized by a high propor tion of proline and serine residues; the serines are potenti targets for kinases.

Discussion

As a member of the segment-polarity class of genes, *ptc* has a key role in the generation of the normal pattern in each segmen in *Drosophila*. Three of these genes, *en*, *gsb* and *wg*, are expressed in restricted domains of each segment; their expression patterns are first established at the blastoderm stage of embryogenesis in response to the activities of pair-rule genes. These segment polarity genes therefore seem to function by registering positional cues generated by pair-rule genes and maintaining this positional specification during subsequent development. Although they are expressed at the boundaries of each paraseg ment[5,11,13], it has been suggested that pair-rule genes have the capacity to specify different positional values throughout each parasegment primordium. This could be achieved either by

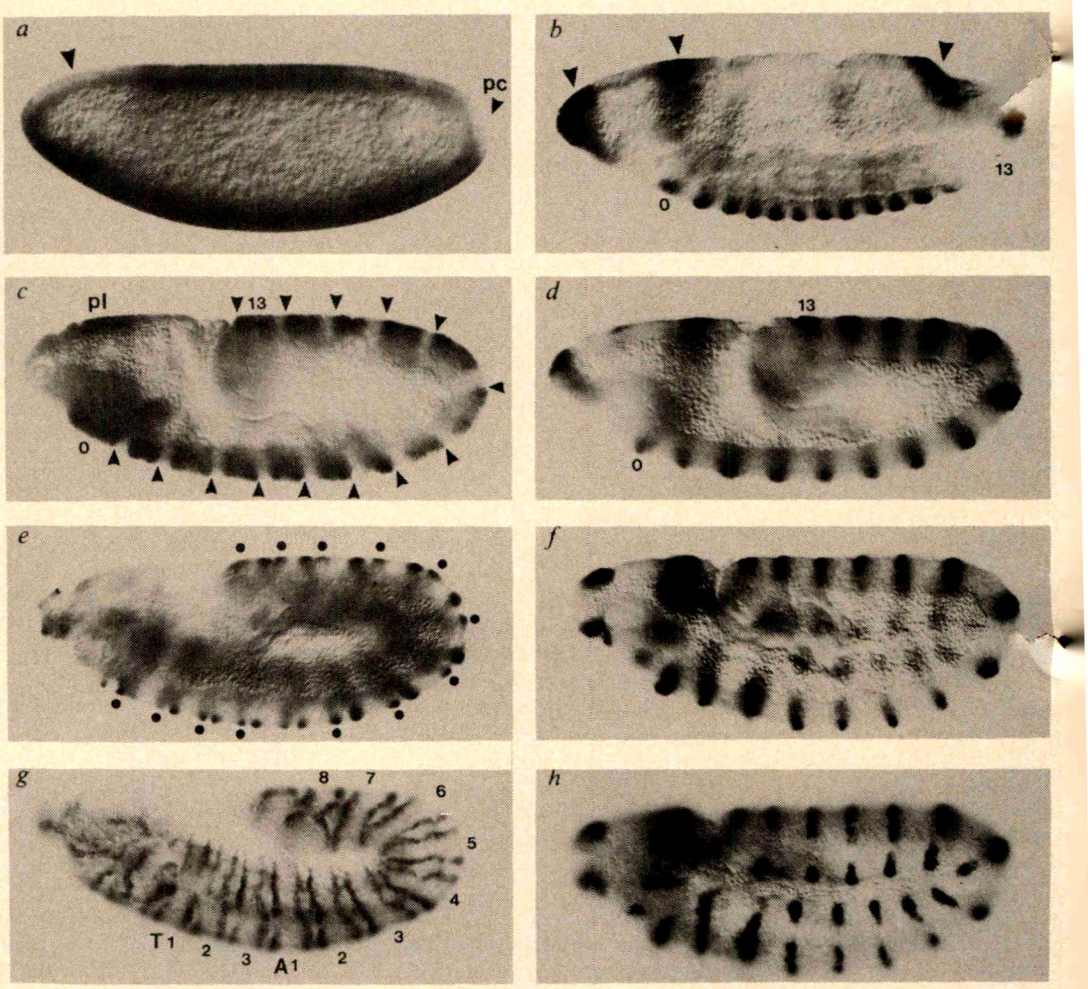

FIG. 3 Comparison of the spatial distribution of *ptc* and *wg* transcripts during embryogenesis. *a*, In the cellularizing blastoderm embryo (stage 5), *ptc* transcripts are almost uniformly distributed, except for an antero-dorsal region (arrow head), where levels are consistently lower and in the pole cells (PC) where no transcripts are detectable. Transcripts are also detectable in the internal yolk nuclei, although they are not visible in this preparation. This pattern contrasts with that of *wg* transcripts *b*, which are initially expressed in three distinct domains (indicated by arrowheads) and which by stage 6 (shown here) are expressed in a series of stripes that mark the posterior boundaries of parasegments 0–13. *c*, After gastrulation, *ptc* expression becomes spatially restricted; in the stage-10 embryo, it is expressed in the posterior three-quarters of the ectoderm of each of parasegments 0–13 (the boundaries of which are indicated by arrowheads). This expression domain is complementary to that of *en* but overlaps the *wg*-expression domains shown in *d*. At this stage, significant expression of *ptc* is also detectable dorsally in the procephalic lobe (PL) in a region bounded by the two anterior domains of *wg* expression. *e*, Towards the end of the extended germ-band stage (stage 12), each band of *ptc* expression in the ectoderm splits in two, with the anterior stripe, which marks the anterior boundary of each incipient segment, showing stronger *ptc* expression than the posterior stripe. The latter, indicated by black dots, coincide with the stripes of *wg* expression shown in *f*. Whereas by this stage most of the *wg*-expression stripes have split into a dorsal and a ventral component[41] *h* the *ptc*-expression stripes *g* remain continuous across the width of each segment (T1–T3, thoracic; A1–8, abdominal). All photographs show embryos orientated anterior to the left, dorsal surface uppermost. Staging is according to Campos-Ortega and Hartenstein[42].

METHODS. Embryos were fixed as described[43] and hybridized with probes prepared from cDNA clones pc2 (*ptc*) or D-int1 (*wg*)[19] labelled with digoxigenin (Boehringer) according to a protocol devised by D. Tautz and C. Pfeile, modified by C. Oh and B. Edgar (personal communication). Signal detection was as described by the manufacturers; embryos were mounted in JB4 (Polysciences) and photographed using Direct Interference Contrast optics on a Zeiss Axioplan microscope.

means of a graded distribution of protein products of the pair-rule genes[27], or through their combinatorial activity in different cells[28]. An implication of these models is that each band of cells in a primordium might register its position by the pair-rule-dependent activation of different segment-polarity genes. In such models, *ptc* would seem a good candidate for spatially regulated activation, because it is the only zygotically expressed segment-polarity gene known to be required for the specification of pattern in the middle region of each segment. We find, however, that at the blastoderm stage, *ptc* expression is almost uniform, its pattern only becoming spatially restricted during germ-band extension. These findings not only argue against a role for *ptc* in allocating specific blastoderm cells to particular pathways of development, but also support the view that such specification is limited to the boundary cells of each primordium[3].

By analysing the sequence of the *ptc* transcript we predicted that it encodes a protein with a structure that is novel among the products of segment-polarity genes[7–9,19,29]. The most striking feature is the presence of several hydrophobic domains, which have the potential to span the plasma membrane. Multiple membrane-spanning domains are a feature of several previously described proteins, which can be classified into two groups. The first includes the mating pheromone receptors of the yeast *Saccharomyces cerevisiae*[30], the cyclic AMP receptor of the slime mould *Dictyostelium discoideum*[31], as well as the adrenergic[32], muscarinic acetylcholine[33] and serotonin[34] receptors in vertebrates. All these proteins have seven transmembrane domains and are coupled to second messengers by means of G proteins. The second group is more diverse, both structurally and functionally, and consists of proteins involved in transport across membranes, such as the erythrocyte band-3 protein[35], the Na^+/H^+ antiporter[36], the glucose transporter[37], and the P glycoprotein[38,39]. In our tentative model of the tertiary structure of the *ptc* gene product, the protein spans the membrane twelve times, has two large potentially glycosylated extracellular domains and intracellular N- and C-terminal ends. This structure differs significantly from that of the G-protein-coupled receptor proteins; in addition, searches of the National Biomedical Research Foundation databases have revealed no significant homology between the *ptc* protein and any other previously described. Thus we conclude that *ptc* encodes a novel form of integral membrane protein.

Genetic analysis of *ptc* has implicated it in the regulation of the expression of both *wg* and *en*. The regulation of *en* expression, at least, depends on local cell interactions[16,17]. In the absence of *ptc* expression, cells anterior to those expressing *wg* in each parasegment apparently respond inappropriately to the intercellular signal encoded by *wg*, and initiate expression of *en*. This indicates that one of the functions of *ptc* could be to modulate the competence of cells to respond to the *wg*-encoded signal[3,16]. This role is consistent with the pattern of *ptc*

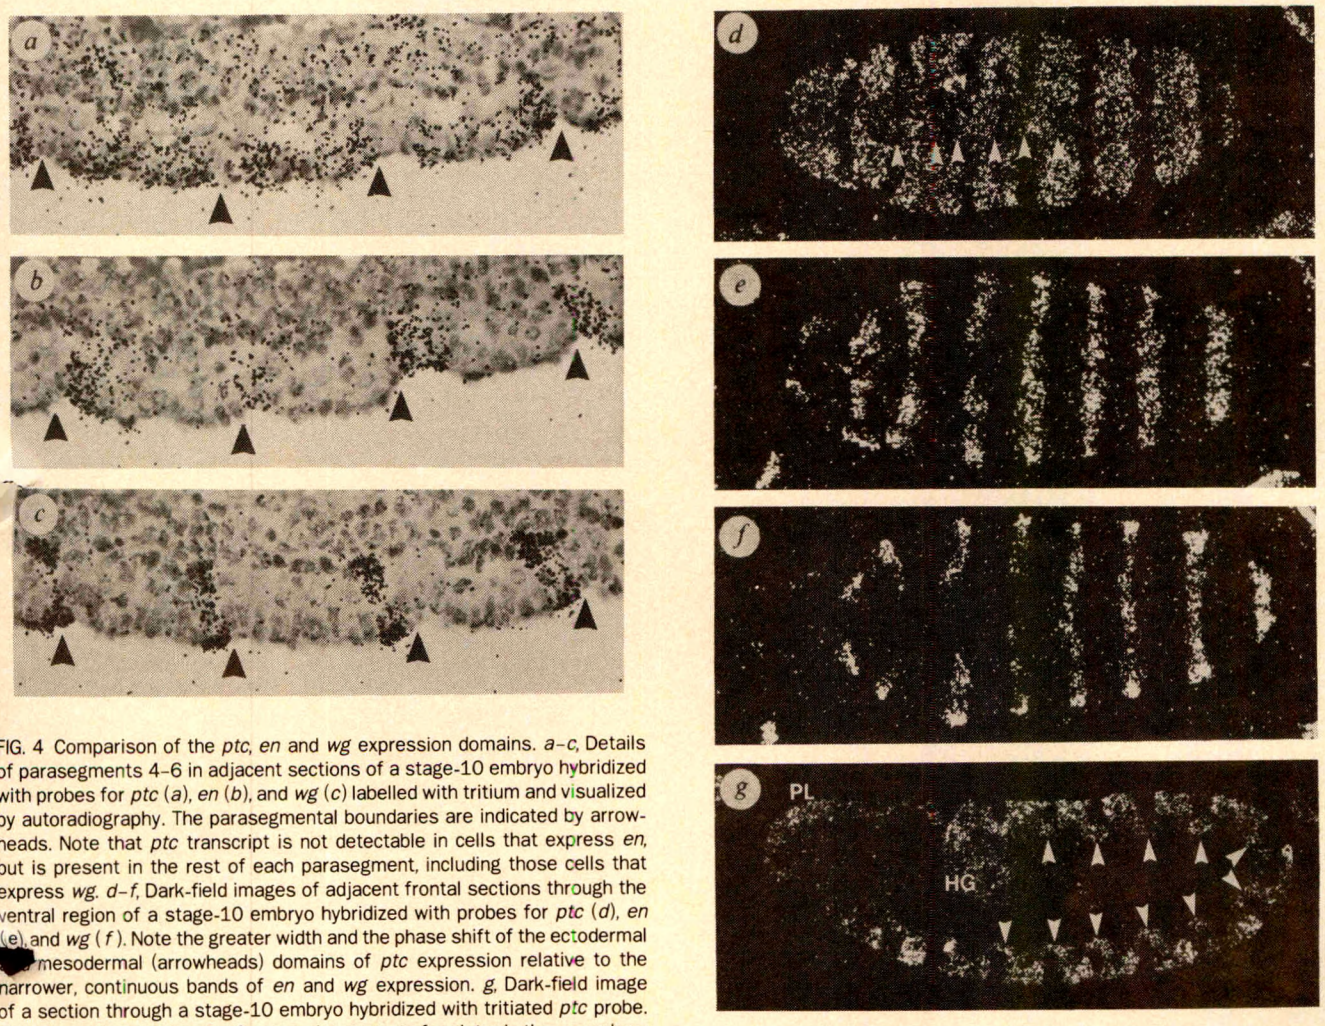

FIG. 4 Comparison of the *ptc*, *en* and *wg* expression domains. *a–c*, Details of parasegments 4–6 in adjacent sections of a stage-10 embryo hybridized with probes for *ptc* (*a*), *en* (*b*), and *wg* (*c*) labelled with tritium and visualized by autoradiography. The parasegmental boundaries are indicated by arrowheads. Note that *ptc* transcript is not detectable in cells that express *en*, but is present in the rest of each parasegment, including those cells that express *wg*. *d–f*, Dark-field images of adjacent frontal sections through the ventral region of a stage-10 embryo hybridized with probes for *ptc* (*d*), *en* (*e*), and *wg* (*f*). Note the greater width and the phase shift of the ectodermal and mesodermal (arrowheads) domains of *ptc* expression relative to the narrower, continuous bands of *en* and *wg* expression. *g*, Dark-field image of a section through a stage-10 embryo hybridized with tritiated *ptc* probe. This shows that the bands of expression are out of register in the mesoderm (arrows) and ectoderm. Note also the expression in the hindgut (HG) and the procephalic lobe (PL).

METHODS. Wax-embedded tissue sections were prepared and hybridized with tritiated single-stranded RNA probes essentially as previously described[43]. Probes were synthesized from cDNA clones pc2 (*ptc*), pwg-c14 (*wg*)[11] and E2C (*en*)[7].

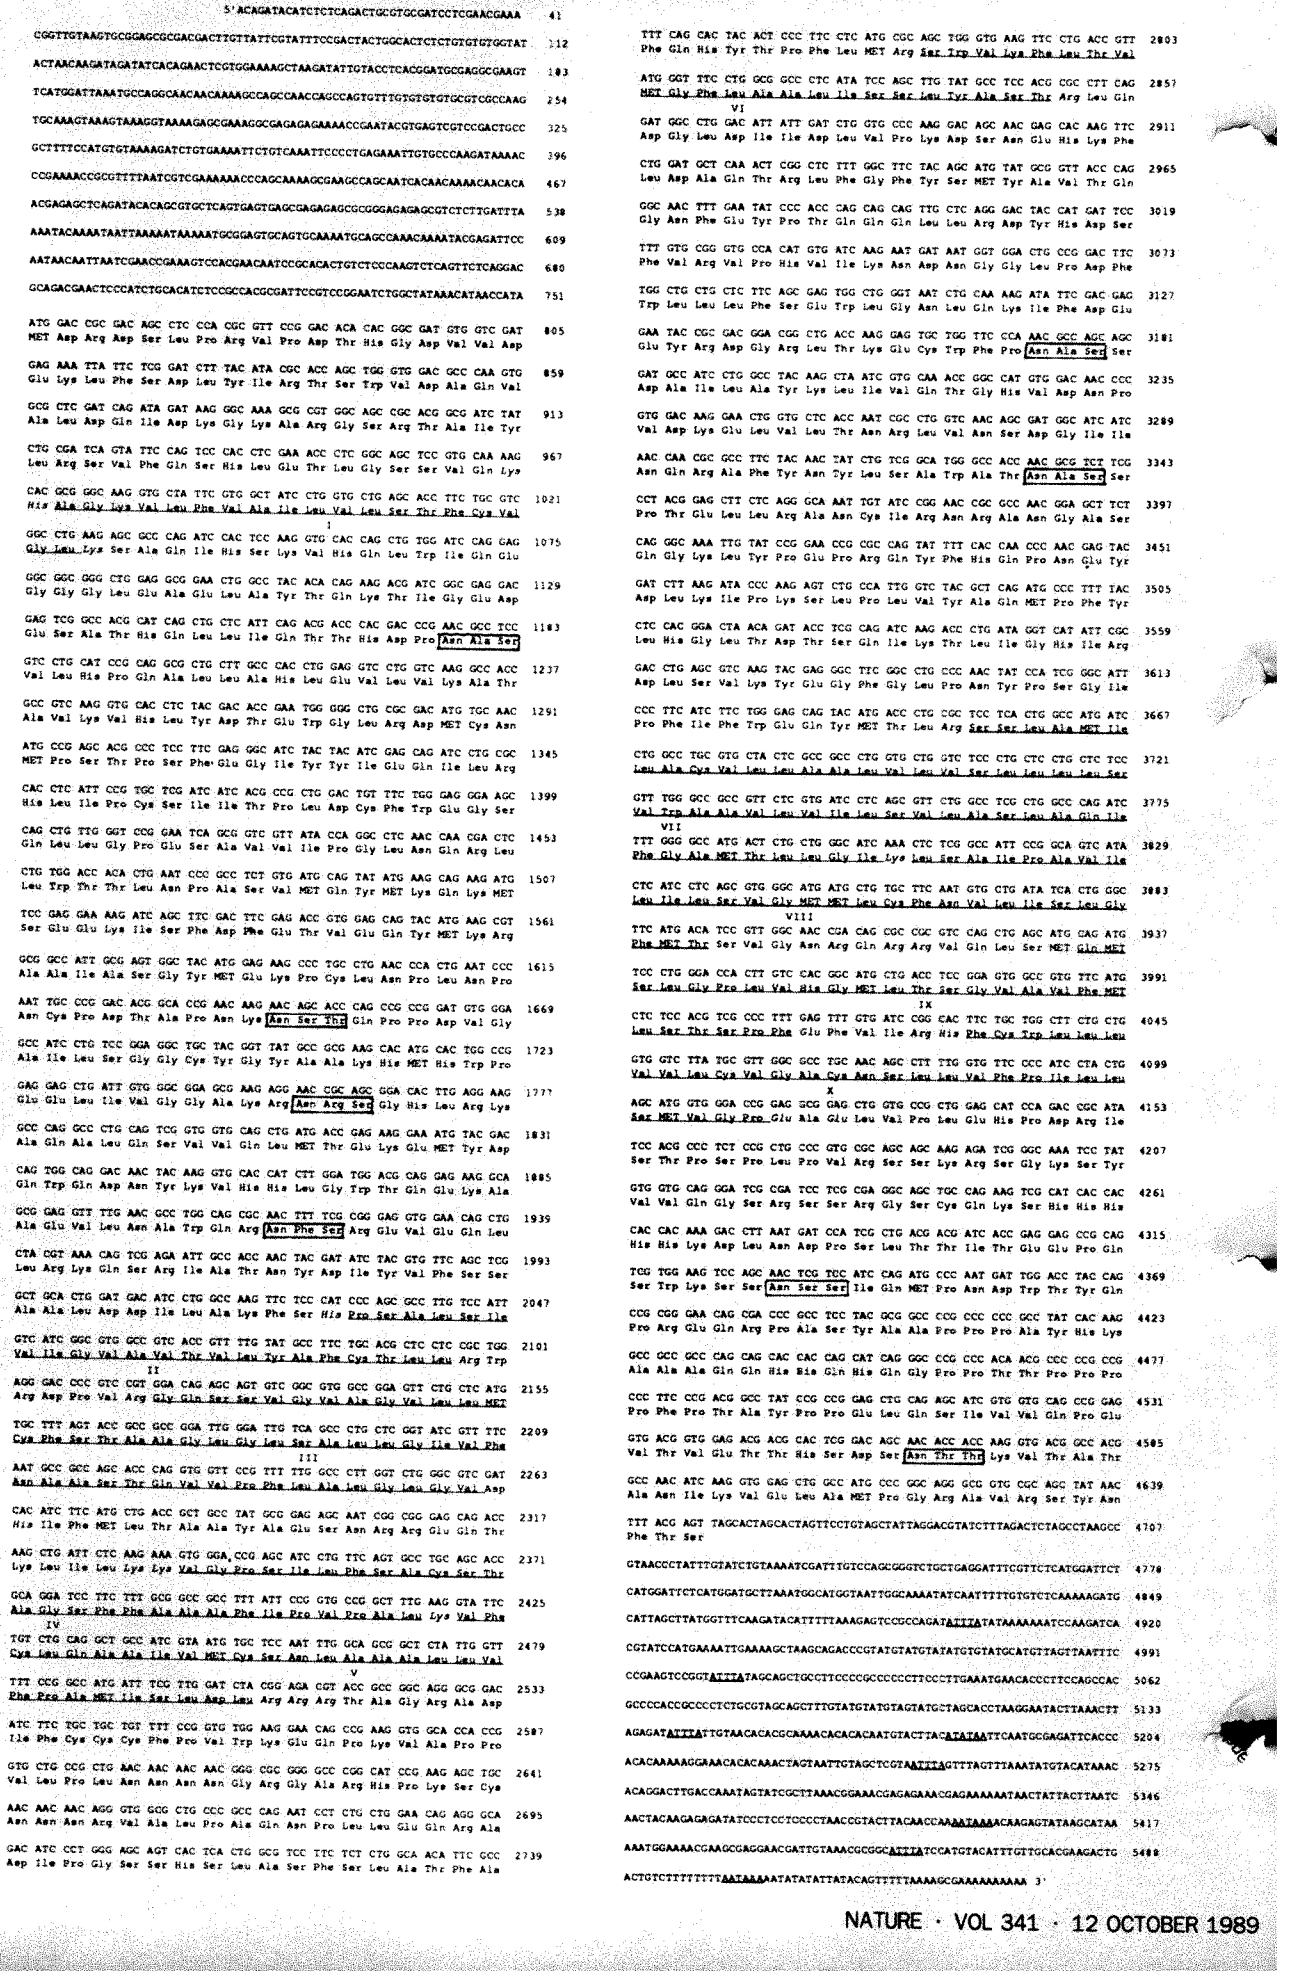

FIG. 5 Nucleotide sequence of the *ptc* gene and predicted amino-acid sequences. Canonical polyadenylation signal (AATAAA), atypical polyadenylation signal (ATATAA) (see text) and mRNA destabilizing ATTTA motifs are underlined. The amino-acid sequence of the longest ORF is shown. Amino-acid sequences underlined correspond to predicted hydrophobic segments (I–X). Clusters of charged residues that are believed to mark the boundaries of membrane-spanning segments are shown in italics. Possible *N*-glycosylation sites (consensus: Asn-X-(Ser/Thr)) are boxed.

METHODS. The cDNA clones described in Fig. 2 were sequenced by the dideoxy technique[20] with Sequenase (US Biochemical). Both nested deletions, generated by *Exo*III and S1-nuclease digestion and oligonucleotides corresponding to previously determined sequences were used in the sequencing reactions. The cDNA clone pc2 corresponds to nucleotides 1–2,583 and pc3 to nucleotides 3,028–5,547. Both strands were sequenced, excluding parts of the untranslated regions between nucleotides 1–213, 426–600, 4,833–4,921 and 5,302–5,547.

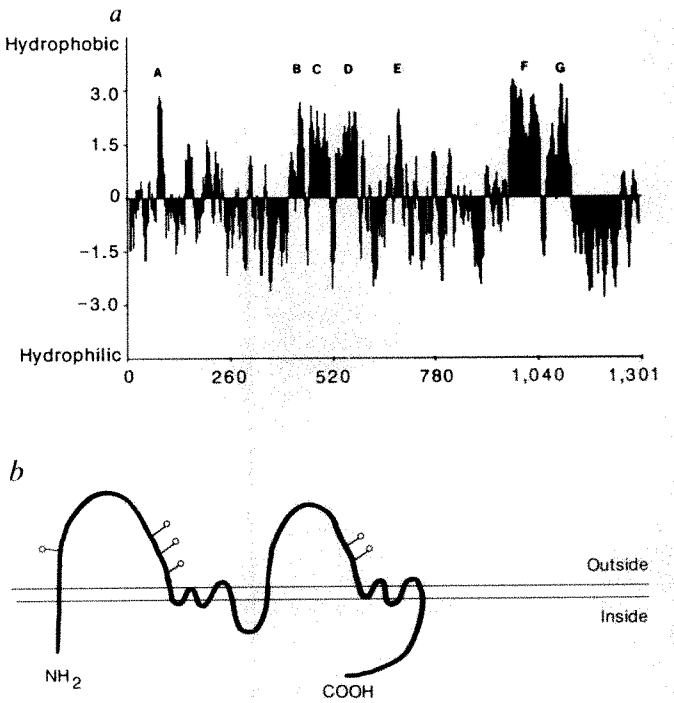

FIG. 6 *a*, Hydropathy plot of the deduced amino-acid sequence of the Ptc protein using the algorithm of Kyte and Doolittle[25] using a window size of 11. The seven hydrophobic regions are designated *A–G*. *b*, Schematic two-dimensional representation of a possible model of the Ptc protein in the plasma membrane (not drawn to scale). Predicted *N*-glycosylation sites are marked with circles. The boundaries of the domains are defined by the charged residues indicated in Fig. 5.

expression that we have described. In stage-10 embryos, all ectodermal cells in each parasegment, except those that express *en*, are found to express *ptc*. Only the latter cells should thus be able to respond to the *wg*-encoded signal by expressing *en*. Of note is that the early repression of *ptc* in the *en*-expressing cells seems to depend on *en* function itself (A.H. and P.W.I., manuscript in preparation), indicating that *ptc* may be a component of a regulatory loop that maintains *en* expression at the parasegmental boundary. Early *en* expression would ensure that cells are competent to respond to a *wg*-encoded signal (by repressing *ptc*), but presumably these cells will respond only if they are in the appropriate location, that is, adjacent to *wg*-expressing cells.

The predicted structure of the Ptc protein indicates several different ways in which it could perform such a function. One possibility is that the *ptc*-expressing cells lose their competence to respond to a *wg*-encoded signal because of an earlier response to some other signal, for which the Ptc protein acts as a receptor. A second possibility is that the expression of *ptc* causes cells to respond differently to the *wg*-encoded signal. For instance, Ptc could change the physiology of expressing cells by mediating a membrane transport process and hence influence the transduction of the *wg* signal. Alternatively, the Ptc protein could interact directly with the receptor for the *wg* signal, coupling it to a different pathway. It is notable that at the beginning of stage 12, *ptc* expression disappears from cells immediately anterior to the *wg*-expression domain, but persists in two distinct domains in each parasegment. Although the reason for this later regulation is unclear (because *ptc* expression would seem to persist only in those parts of the segment unaffected by its absence), it has important consequences for models that postulate concurrent activity of *wg* and *ptc*, implying that there is a rather narrow period during which cells normally respond to the *wg*-encoded signal.

At this stage we cannot easily discriminate between these various models; further analysis of the structure of the Ptc protein should lead to a better understanding of its function and of the cellular interactions that underlie cell patterning in the larval ectoderm.

Note added in proof: An independent molecular analysis of *ptc* has also been recently described by J. Hooper and M. P. Scott (*Cell*, in the press). □

Fluvial valleys and martian palaeoclimates

Virginia C. Gulick* & Victor R. Baker*†

* Department of Geosciences and † Department of Planetary Sciences, University of Arizona, Tucson, Arizona 85721, USA

NETWORKS of small fluvial valleys are extensively developed throughout the ancient heavily cratered terrains of Mars[1–3]. The existence of the valleys has been cited as compelling evidence for a relatively dense primordial atmosphere capable of maintaining an Earth-like hydrological cycle. Theoretical models of early atmospheric evolution[4,5] describe the maintenance of a dense CO_2 atmosphere and a warm, wet climate until the end of the heavy-bombardment phase of impacting. However, the presence of very young, Earth-like fluvial valleys on the northern flank of Alba Patera[6–8] conflicts with this scenario. Whereas the widespread ancient martian valleys generally have morphologies indicative of sapping erosion by the slow outflow of subsurface water[9,3], the local Alba valleys were probably formed by surface-runoff processes. Because subsurface water flow might be maintained by hydrothermal energy inputs[10,11] and because surface-runoff valleys developed late in martian history, when planet-wide climatic conditions were presumably similar to the present, it is not necessary to invoke drastically different planet-wide climatic conditions to explain valley development on Mars. The Alba fluvial valleys can be explained by hydrothermal activity or outflow-channel discharges that locally modified the atmosphere inducing precipitation and local overland flow on low-permeability volcanic ash.

The widespread valley networks of Mars are predominantly associated with the heavy-bombardment phase of cratering history[12], corresponding to the Noachian Period[13]. Local areas of younger valleys are recognized[14], but nearly all martian valleys show remarkably low drainage densities, ranging from 0.015 to 0.16 km per km^2 (ref. 15). This contrasts with the nearly ubiquitous terrestrial fluvial dissection, in which the minimum observed value is ~1.0 km per km^2 (ref. 16). The sapping mechanism[17] is generally invoked to explain this and other dissimilarities between martian networks and terrestrial valleys of rainfall-runoff genesis. Sapping occurs when ground water discharges to the surface at a point of geological control (joint, fault or pre-existing valley, for example) and undermines the overburden to generate headward erosion at its point of emergence.

The Noachian martian valleys probably formed before the end of late heavy bombardment (2.8–3.8 Gyr BP) (refs 18–20). The absolute age of the very young valleys on Alba Patera, however, is less constrained (2.6–0.5 Gyr BP) (refs 18, 19). Crater based and geochronological criteria classify Alba as post heavy bombardment[12] and Early Amazonian[13], respectively. Valleys on Alba Patera were formed both by fluvial processes and by lava-flow processes. Some valleys display multigenetic features indicating that both fluvial and lava-flow processes were important in their formation. Monogenetic fluvial valleys, however, formed only on the northern flank of Alba in regions where lava-flow morphology is less common or absent (Fig. 1). The surface on which these valleys formed is relatively smooth and appears to be mantled, probably by ash[6,8]. Adjacent to these smooth areas are prominent lava flows, with pristine morphology. Lava tubes and channels formed on these flows, often display a discontinuous, pitted-surface morphology or form distributary patterns[6,8]. By contrast, fluvial valleys on Alba display a continuous surface morphology and form a complex system of branching tributary networks which are characteristics typical of terrestrial river valleys.

The exact nature of processes causing the local fluvial valleys on the northern flank of Alba is the major concern. A sapping origin has been proposed[21], but our morphological and terrestrial analogue studies[6,8,22] indicate that the characteristics of the fluvial valleys on Alba Patera are more compatible with a formation by surface runoff. Runoff valleys form when surface water flows moving downslope erode into the underlying land surface. Alba valleys have a V-shaped cross-section, and headwater regions that blend in gradually with the surrounding landscape. Some of the larger valleys present in the very high resolution frames (Fig. 2) may show signs of incipient valley enlargement by sapping. Unlike the Noachian valley networks, however, the local Alba valleys do not generally exhibit such sapping attributes as broad flat floors, theatre heads or structural control by faults or joints. Instead, the overall pattern is morphologically similar to that of valleys formed by rainfall runoff on Hawaiian volcanoes (Fig. 1).

We propose that the Alba valleys developed in a manner similar to fluvial valleys formed on terrestrial volcanoes. On Earth, fluvial valley development on volcanic landscapes is a progressive sequence of formation by surface runoff and subsequent modification by sapping. The rate at which these processes proceed is a function of climate, time, lithological properties, slope and stream process (surface runoff or ground-water sapping)[23,22]. In general, fluvial valleys cannot form on volcanic landscapes until the permeability of the basalt flows is reduced either through the emplacement of an aeolian mantle, ash mantle or by weathering of the basalt surface[6,8,22]. When the rate of infiltration becomes less than the rate of runoff, valleys are formed by surface runoff. On Alba Patera, fluvial runoff valleys could have formed only in regions where surface water supply and lithological conditions were amenable to runoff. These factors resulted in drainage densities for local Alba valleys of 0.3–1.5 km per km^2, an order of magnitude higher than generally observed for the Noachian valleys. These values are comparable to measurements on the dry leeward side of Hawaiian volcanoes, including Kilauea (0.6–3.0 km per km^2), Mauna Kea (0.3–5.0 km

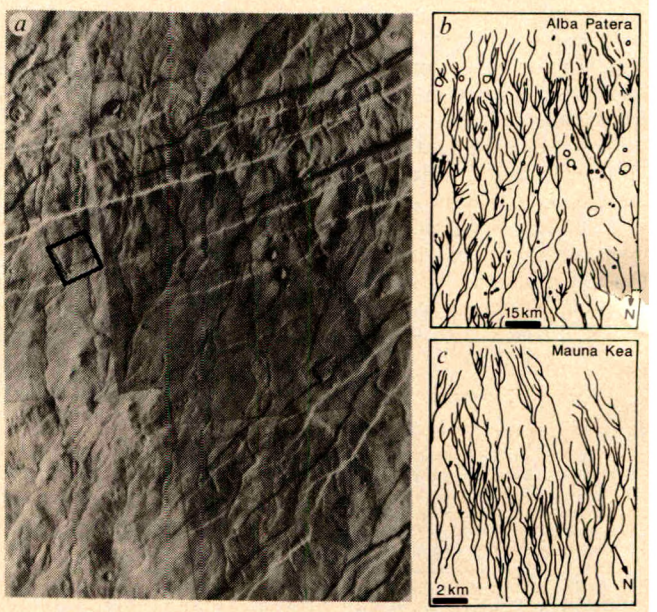

FIG. 1 *a*, High-resolution photomosaic of fine-textured fluvial valleys on the northern flank of Alba Patera. Valleys are formed in a region where lava-flow morphology is absent, indicating that the region was mantled, probably by ash. These valleys are the most highly integrated fluvial valleys on the surface of Mars. The high degree of fluvial (runoff) valley development on such a young volcano indicates that a mechanism capable of providing sustained surface water flow (at least locally on Alba) operated long after the end of the heavy-bombardment phase of impacting. Downslope direction is toward the north (from Viking photomosaic: MTM 45107) (Boxed area denotes location of image in Fig. 2). *b*, Drainage map of fluvial valleys in *a*. The Alba valleys form highly integrated transitional parallel-to-dendritic drainage patterns similar to those formed by rainfall runoff on the Hawaiian volcanoes (such as *c*, Mauna Kea).

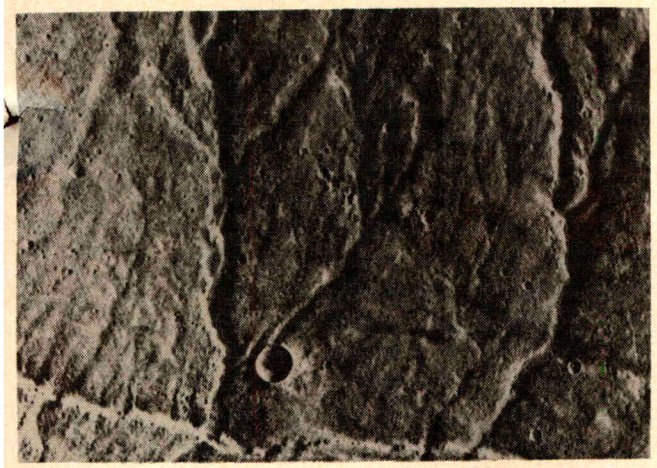

FIG. 2 Very-high-resolution images (7 m per pixel) (see location in Fig. 1*a*) of the fluvial valleys on Alba Patera. The tapered valley heads (see also Fig. 1*a*) which blend in gradually with the surrounding terrain, V-shaped cross-valley profiles (when viewed in stereo) and the lack of structurally controlled drainage patterns suggest a formation by surface runoff. When viewed in stereo, the larger valleys in this photograph seem much deeper than the others and have downcut into resistent subsurface layers (that is, basalt or welded ash). If these layers are permeable basalt, then some of this enlargement may reflect incipient sapping processes. However, the cross-valley profiles are distinctly V-shaped indicating that surface runoff was still the dominant process when valley formation ceased. (Diameter of large crater is ~1 km) (Viking frames: 445B07–08).

per km^2) and Kohala (0.2–2.8 km per km^2) (refs 7, 22).

In Hawaii, valleys evolve with time as the low-permeability ash and weathered lava are eroded. Deep incisions tap ground water and the valleys transform to a sapping morphology[24,3,6,22]. On Mars, fluvial valleys are also present on the volcanoes Ceraunius Tholus and Hecates Tholus, which formed before the end of late heavy bombardment[12,18,19] (Fig. 3). Drainage-density values for valleys on all three volcanoes are similar, but the Alba valleys are better integrated. Valleys on Ceraunius and Hecates have initially formed by surface runoff but, unlike the Alba valleys, the Ceraunius and Hecates valleys were extensively enlarged or reactivated, probably by sapping. The less integrated (and therefore less developed) nature of the fluvial valleys on Ceraunius and Hecates suggests that less surface water was available during valley development. The presence of extensive valley modification on these volcanoes indicates, however, that fluvial valleys developed over a very long time. Long periods ($>10^5$ yr) of ground-water flow are needed to produce the degree of valley modification present. Such sustained flow would have required a recycling mechanism.

The indicated history of martian fluvial-valley formation poses an interesting dilemma. The widespread Noachian valleys are less indicative of atmospheric hydrological cycling than are the local Alba valleys of anomalously young age. Because water can flow as ice-covered rivers on Mars even for present-day atmospheric conditions[25], it is the sustained discharge to the surface that is the limiting factor in valley formation on Mars. For sapping valleys, flow can be maintained either by recharge from atmospheric precipitation or by circulation in subsurface hydrothermal systems. Atmospheric-water transfer may only be required when valley morphology indicates surface-water runoff processes.

A variety of mechanisms seem capable of supplying precipitable water to the local vicinity of Alba under mean climatic conditions not drastically different from those of today. The ultimate water source is the extensive subsurface reservoir indicated by abundant geomorphological evidence of ground water and ice[26,3]. Vapour from eruptions and explosive activity emanating from Alba Patera could have transported some of this water into the surface environment[21]. Even more important for valley formation would be the development of prolonged hydrothermal circulation within the water or ice-rich subsurface materials underlying the low-relief volcano. Hydrothermal systems are capable of melting ground ice, focusing the resulting flow of ground water into narrow effluent zones and then transporting these fluids to the surface (by seeps and springs for example). Ground water can be recirculated through these systems for several million years[11]. By comparison, fluvial valleys on the Hawaiian volcanoes generally formed in ~10^4–10^5 yr (refs 8, 22). Therefore such circulation should have persisted over the timescales needed for fluvial valley formation on Alba Patera. Also, as on Earth, locally warmer, more moist environments might have developed near regions of hydrothermal activity and thereby induced areas of enhanced precipitation along the perimeter of these zones. Even snow accumulation in such areas could have yielded surface water flow under present climatic conditions[27].

Because the outflow channels developed at approximately the same time as Alba[12], an additional source of atmospheric moisture may have been derived from outflow discharges[28]. Using the present topography[29], the minimum amount of water required to erode the outflow channels[26] could have formed a temporary circumpolar body of water on the northern martian plains with an average depth of 660 m and a surface area of 1.1×10^7 km^2. This assumes that water lost to evaporation and infiltration was equivalent to the volume of water in excess of the minimum amount of water required to erode the outflow channels. The climatic influence of the hypothesized circumpolar sea and its ice cover would have been a temporary aberration from mean, planet-wide conditions. The prevailing northerly winds at this latitude[30] would move saturated air from this sea to Alba, where orographic precipitation might occur as

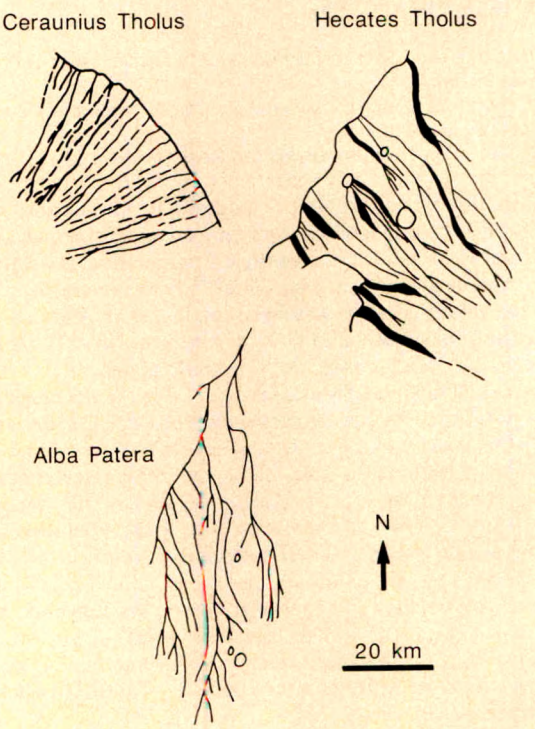

FIG. 3 Comparison figure of representative drainage patterns on the martian volcanoes: Ceraunius Tholus, Hecates Tholus and Alba Patera. Well developed drainage patterns on Alba indicate that considerable water was present at the surface during fluvial valley formation. The lack of reactivation (as is apparent on Ceraunius (solid lines)) or enlargement (as is apparent on Hecates (shaded black areas)) of the valleys on Alba, however, suggests that the period of fluvial valley activity on Alba was relatively short-lived.

on the windward flanks of the Hawaiian volcanoes. Whatever the precipitation mechanism, water would rapidly infiltrate the highly permeable volcanic rocks, precluding surface flow except in the area where low permeability ash mantles the northern flanks of Alba. There, the local occurrence of surface runoff would lead to the distinctive Earth-like valley pattern (Fig. 1).

The anomalously young age and the surface-runoff origin of the Alba valleys have important implications for understanding the climate history of Mars. Whatever the local mechanisms of their origin, the Alba valleys formed late in martian history when mean planet-wide conditions were presumably similar to those at present. It seems inappropriate therefore, to assume for models of martian atmospheric evolution[4,5] that a persistent mean climatic epoch drastically different from that of today is required to explain the valley networks that formed during the heavy bombardment period. On Mars, as on Earth, valley genesis may occur through a variety of local processes. □

Latitudinal variations in plankton $\delta^{13}C$: implications for CO_2 and productivity in past oceans

THE stable-carbon isotopic composition of marine organic material has varied significantly over geological time, and reflects significant excursions in the isotopic fractionation associated with the uptake of carbon by marine biota[1–8]. For example, low $^{13}C/^{12}C$ in Cretaceous sediments has been attributed to elevated atmospheric (and hence oceanic) CO_2 partial pressures[3,4,8]. A similar depletion in ^{13}C in present-day Antarctic plankton[2,9–12] has also been ascribed to high CO_2 availability[3,4]. We report, however, that this high-latitude isotope depletion develops at CO_2 partial pressures (pCO_2 levels) that are often below that of the present atmosphere (340 μatm), and usually below that of equatorial upwelling systems (>340 μatm). Nevertheless, because of the much lower water temperatures and, hence, greater CO_2 solubility at high latitude, the preceding pCO_2 measurements translate into Antarctic surface-water CO_2 (aq) concentrations that are as much as 2.5-times higher than in equatorial waters. We calculate that an oceanic pCO_2 level of > 800 μatm (over twice the present atmospheric pCO_2) in a warmer low-latitude Cretaceous ocean would have been required to produce the plankton ^{13}C depletion preserved in Cretaceous sediments.

Plankton of the South Atlantic Ocean and Weddell Sea (Antarctica) exhibit a dramatic decrease in $\delta^{13}C$ as a function of both latitude and sea surface temperature (Fig. 1*b*). This isotope trend does not parallel the relatively constant $\delta^{13}C$ of the associated total dissolved inorganic carbon TCO_2 (Fig. 1*a*). Because some small fraction of this TCO_2 provides a substrate for plankton biomass formation (through phytoplankton carbon fixation), the increasing difference in isotopic composition between plankton and TCO_2 therefore requires a fundamental change in the carbon biogeochemistry and associated isotope fractionation with changing temperature and latitude.

The strong relationship between temperature and plankton $\delta^{13}C$ was initially interpreted as a direct temperature effect on plankton isotope abundances, possibly resulting from temperature-sensitive changes in the kinetic isotope effect associated with phytoplankton CO_2 fixation [9,13,14]. However, subsequent laboratory experimentation[15–18] as well as further field sampling and analysis[13,14,19] failed to find consistent trends with either controlled temperature or ocean temperature. Large interspecies differences in phytoplankton $\delta^{13}C$ response to temperature were noted[15,18], and species and water-mass effects were later used to interpret some of the isotope variability observed in the ocean[2,13,14,19,20]. The significant ^{13}C depletion in Southern Ocean plankton, however, remained largely unexplained.

Other experiments demonstrated a strong relationship between external CO_2 concentration and $\delta^{13}C$ in marine plants[15–17,21]. It was shown that increasing CO_2 availability generally results in a decrease in plant $\delta^{13}C$ and an increase in the difference between the $\delta^{13}C$ of the plant and that of the CO_2 it uses. This difference, $\Delta_{c\text{-}p}$ ($= \delta^{13}C_{CO_2} - \delta^{13}C_{plant}$), expresses the overall fractionation factor associated with carbon fixation by plants. $\Delta_{c\text{-}p}$ has been observed to range from near 0‰ at low CO_2 concentrations to as high as 28‰ at CO_2 concentrations of >5% CO_2 (v/v in air) (refs 21, 22). This has led to speculation that high pCO_2 was responsible for the low $\delta^{13}C$ and higher apparent $\Delta_{c\text{-}p}$ values indicated in the marine sedimentary record[1,3,4,8,17,21] and observed in contemporary Antarctic plankton[3,4].

Figure 1*c* shows, however, that pCO_2 levels in Antarctic surface waters are not significantly elevated relative to those at lower latitudes. In fact pCO_2 levels in the Weddell Sea are frequently much lower than those encountered in equatorial waters. We point out, however, that to relate pCO_2 to the dissolved CO_2 concentration, $[CO_2(aq)]$, temperature-sensitive CO_2 solubility as described by Henry's law must be considered as follows:

$$[CO_2(aq)] = a \times pCO_2 \quad (1)$$

Using known solubility constants, *a* (ref. 23), the calculated ranges of $[CO_2(aq)]$ for the South Atlantic and Weddell Sea show, on average, a dramatic increase in dissolved CO_2 concentration with decreasing temperature and increasing latitude ([illegible] *b*). Again, these increases are due to the greater solubility [illegible]$_2$ at lower water temperatures for a given pCO_2 level, a [illegible]onship that is closely approximated by a second-order [illegible]omial equation (Fig. 1*b*).

[illegible]he above observation of as much as 2.5 times more $[CO_2(aq)]$ [illegible]igh latitudes relative to that of low latitudes may then be [illegible]ing the plankton $\delta^{13}C$ trends with latitude and temperature. [illegible] could occur because Δ_{c-p} increases with increasing [illegible]$O_2(aq)$][15–17,21,22,24,25] or because Δ_{c-p} remains constant but [illegible] $\delta^{13}C$ of both the CO_2 and the phytoplankton increase as a [illegible]gnificant fraction of the CO_2 is converted to biomass following [illegible]he Raleigh distillation model of a closed system[26,27]. An increase [illegible]f Δ_{c-p} with increasing $[CO_2(aq)]$ (the first mechanism) may involve a corresponding decrease in the relative importance of bicarbonate (rather than CO_2) as an initial substrate for phytoplankton carbon fixation[20,22,24]. It could also involve reduced phytoplankton demand for CO_2 at high latitude. Estimates of open-water primary production (net CO_2 uptake) in the Weddell Sea of 10–20 g C m^{-2} yr^{-1} (refs 28, 29) are significantly lower than those of equatorial Atlantic waters. A reduced internal demand for CO_2 in combination with elevated external CO_2 concentration may then result in greater expression of the kinetic isotope fractionation associated with CO_2 fixation[22] and therefore lower plankton $\delta^{13}C$ at high latitude.

If changes in phytoplankton species composition and associated Δ_{c-p} values[14,18,20] were contributing to the observed variation of $\delta^{13}C$ with latitude, one would expect to see nonuniformities or breaks in the plankton $\delta^{13}C$ trend with temperature and latitude as various water-mass regimes and phytoplankton species compositions were transected in the Southern Ocean. Such breaks are not evident in Fig. 1*b*, nor are they apparent in the plankton isotope-temperature (<25 °C) trend reported in ref. 14.

A linear relationship between marine plankton $\delta^{13}C$ and $[CO_2(aq)]$ is indicated by their similar trend with temperature (Fig. 1*b*), as has been previously suggested[30]. Changes in freshwater plankton Δ_{c-p}, however, have been described as a linear function of log $[CO_2(aq)]$ based on extensive experimental and field measurements in several New Zealand lakes[25]. However, determination of the true relationship between *in situ* marine plankton $\delta^{13}C$ and $[CO_2(aq)]$ (and therefore possible insight into the biogeochemical mechanism(s) involved) will require simultaneous measurement of these two variables over broad temporal and spatial scales in the ocean, data which are presently unavailable.

In the meantime, we suggest that much of the carbon isotope variability of plankton observed in the Southern Ocean, if not elsewhere, is directly related to variations in $[CO_2(aq)]$. A strong relationship between temperature and plankton $\delta^{13}C$, sometimes evident in past field (for example, Fig. 1*b*) and laboratory studies, may have been an indirect one, resulting from the aforementioned temperature effects on CO_2 solubility and concentration. It is not easy to address this point using the data of many of these past studies because pCO_2, $\%CO_2$ in feed gas and/or TCO_2 concentrations were reported rather than the more relevant $[CO_2(aq)]$.

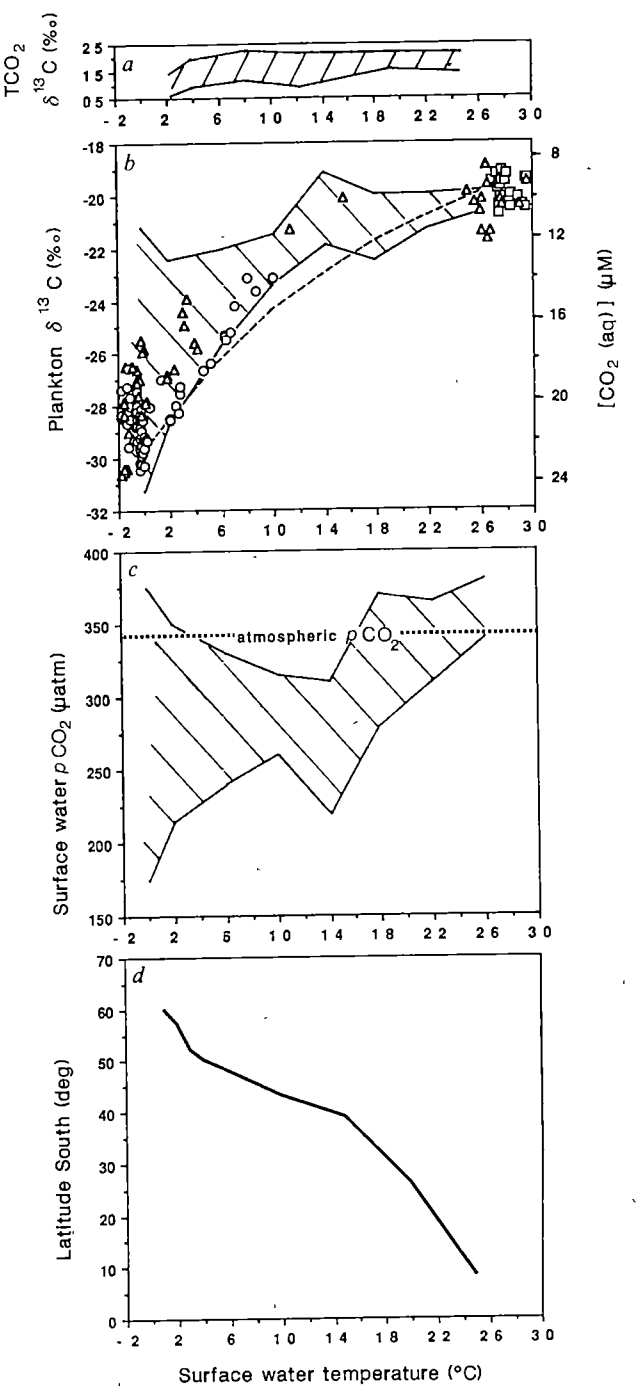

FIG 1 *a*, Range of total dissolved inorganic carbon (TCO_2) $\delta^{13}C$ as a function of surface water temperature in the South Atlantic and Southern Oceans[35] $\delta^{13}C=\{R_{sample}/R_{PDB\ std}-1\}\times1{,}000(‰)$ where $R=^{13}C/^{12}C$ of the sample or the PDB carbonate standard. The analytical precision of these measurements is typically $<\pm0.2‰$. *b*, Plankton $\delta^{13}C$ and $[CO_2(aq)]$ as a function of surface water temperature in the S Atlantic and Southern Oceans, and in the Weddell Sea Isotope and temperature data from refs 2 and 9 (triangles), ref. 14 (squares), and G H R., unpublished data (circles) Shaded-area is the range of $[CO_2(aq)]$ as a function of temperature as calculated from the pCO_2 data (Fig 1*c*) using Henry's law (equation (1)) and known solubility constants[23] assuming a salinity of 34 p.p t The dashed line represents surface-water equilibrium values under an atmospheric pCO_2 of 340 μatm As a function of sea surface temperature *T*, this dashed line is closely described by the equation $[CO_2(aq)]_{equil}=22.04-0.77T+0.017T^2$ Note that $[CO_2(aq)]$ is graphed to increase from top to bottom to emphasize its apparent inverse relationship with plankton $\delta^{13}C$ Based on their common trend with temperature, the relationship between plankton $\delta^{13}C$ and $[CO_2(aq)]$ seems to be first order and may be approximated by the equation Plankton $\delta^{13}C=-0.8[CO_2(aq)]-12.6$ as determined by the relationship between the scales of the left and right vertical axes *c*, Range of surface sea water pCO_2 at ambient temperature as a function of sea water temperature in the S. Atlantic, Southern Ocean and Weddell Sea[36] A modern atmospheric pCO_2 of 340 μatm is indicated *d*, Approximate latitude corresponding to a given mean sea surface temperature in the S Atlantic and Southern Oceans

Present-day Antarctic plankton and the sedimentary remains of Cretaceous-age marine plankton communities have several features in common. As well as their similar low $\delta^{13}C$ values[3,4], reoccurring organic-rich horizons within Cretaceous marine sediments and Antarctic plankton have unusually low $^{15}N/^{14}N$ ratios (refs 11, 12, 31), and very low abundances (or little evidence) of carbonate-forming plankton[4]. Furthermore, low phytoplankton productivity probably characterized the Cretaceous Atlantic Ocean[32] as it does present-day Antarctic waters[28,29]. Although atmospheric and ocean pCO_2 levels were probably elevated in the Cretaceous[33,34], only low-temperature, high-latitude marine systems today provide CO_2(aq) concentrations and therefore plankton $\delta^{13}C$ values similar to those that were apparently present in much of the warmer[33,34] Cretaceous ocean. A Cretaceous sediment mean $\delta^{13}C$ value of −27‰ (refs 3, 4) would, as a plankton $\delta^{13}C$ value in today's ocean, correspond to a [CO_2(aq)] of ~20 μM (Fig. 1*b*). Using equation (1), the oceanic pCO_2 required to generate a similar [CO_2(aq)] in a warmer (32 °C, for example), low-latitude Cretaceous ocean would be >800 μatm or more than twice the pCO_2 of the current atmosphere. This is within the range of the 2–13 times higher pCO_2 previously estimated[33,34] to exist globally during the Cretaceous period. Further research on the relationship between plankton $\delta^{13}C$ and CO_2(aq) concentration may lead to refinements in our understanding of CO_2 biogeochemistry in both past and present oceans. □

Direct dating of Phanerozoic sediments by the ^{238}U–^{206}Pb method

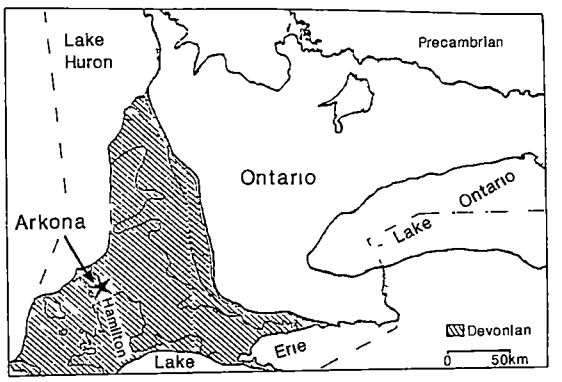
Patrick E. Smith & Ronald M. Farquhar

Geophysics Laboratory, Department of Physics, University of Toronto, Toronto, Ontario, Canada, M5S 1A7

DIRECT radiometric age determination of Phanerozoic carbo has been a long-standing problem in geochronology. Rb–Sr K–Ar dating schemes, commonly used to constrain the chrono of Phanerozoic sediments, have so far proved to be unsuccess in dating these rocks because of their poor enrichment in radiogen ^{87}Sr and ^{40}Ar and also because of analytical difficulties. Rece studies[1,2] have demonstrated that large amounts of radiogenic P exist in some carbonates and that they could be dated by the Pb–Pb method. However, the precision of this method is severely limited to samples having very high uranium to lead ratios because by the beginning of the Phanerozoic (~590 Myr ago) 98% of ^{235}U originally present in the Earth had decayed to ^{207}Pb. Here we report the first isochron age of carbonates using the ^{238}U–^{206}Pb method on corals. This method, which gives good accuracy even for low U concentrations, has great potential for the direct dating of sedimentary sequences and should be valuable for refining the Phanerozoic timescale.

We obtained samples from the late Middle Devonian (Givetian) sediments of the Thedford–Arkona region in southwestern Ontario, Canada. The area consists of a 27-m section of fossiliferous shale and limestone of the Hamilton group which has been subdivided into three units: the Arkona, Hungry Hollow and Widder formations. Lithological and biostratigraphic correlation of the rocks is straightforward and is summarized in the stratigraphic section in Fig. 1 (refs 3 and 4). The Arkona formation consists of 12 m of a soft bluish calcareous shale. Two parts of the Hungry Hollow formation may be distinguished—0.5 m of encrinal limestone overlain by a 'coral zone', and a 1-m bed of coral-rich shale. The Widder formation consists of 13 m of shales interbedded with highly fossiliferous limestone. The sediments of this area are well preserved and the burial temperature was probably no more than 150 °C (ref. 5).

We sampled rugose corals of the genera *Heliophyllum* and *Cystiphylloides* from the 'coral zone' of the Hungry Hollow member. Their remains consist of secondary low-magnesian calcite in the form of replaced skeletal elements, infilling micrite and subordinate sparry calcite. Very small amounts of authigenic pyrite are disseminated throughout the corals. We also sampled the limestone from the lower part of the Hungry Hollow formation (Ark-14), limestone from the overlying Widder formation (Ark-4) and pyrite infilling from a brachiopod (*Mucrospirifer*) in the Arkona shale (Ark-3).



We measured Pb, U and Th using a custom-built 30-cm 90°-sector mass spectrometer. Details on the chemical extraction techniques will be presented elsewhere. We determined concentrations of U, Th and Pb by isotope dilution using a mixed ^{235}U–^{230}Th–^{208}Pb tracer (see Table 1). The Pb and U blanks were 190–410 and 12–20 pg, respectively. We calculated the ages using the decay constants recommended in ref. 6 and obtained the isochrons using the line-fitting method in ref. 7. The uncertainty limits drawn on the diagrams are at the 2σ level.

Bulk Pb concentrations for the corals range from 200–300 p.p.b. (parts per 10^9), levels very similar to modern corals[8]. Rugose corals became extinct in the Permian so we cannot make direct comparisons with extant unaltered taxa. These corals differ from most modern Scleractinian corals in that they made their skeletons of magnesian carbonate rather than aragonite[9]. Compared to sea water, however, modern corals of both types of $CaCO_3$ are known to concentrate Pb up to 300 times more

Ca (ref. 10). Thus, the Pb concentration levels in the rugose could reflect original Pb precipitated from Devonian sea without diagenetic modification. Bulk U contents in the corals range from 46–82 p.p.b., much lower than the levels of 1–3 p.p.m. found in modern aragonitic corals[11]. Little is known about the U contents of modern magnesian calcite coral skeletons. It is well known that assimilation of U by marine organisms and its resultant abundance in lithified sediments involves both biological and diagenetic controls[10,12]. The low U contents measured in rugose corals may be attributed in part to loss during diagenetic transformation of their skeletons to low-magnesian calcite. Without knowledge of the original concentrations, however, the degree to which this has happened is uncertain. In any case, the μ ($^{238}U/^{204}Pb$) values of rugose corals are much lower than those of modern corals.

The isotope data for the corals form a linear trend on the Pb isotope correlation plot (Fig. 2*a*) but there is insufficient radiogenic Pb (maximum 2.7%) to define a precise Pb isochron. On a plot of $^{206}Pb/^{204}Pb$ against $^{238}U/^{204}Pb$ (Fig. 3), however, data for the corals form a nine-point isochron corresponding to an age of 376 ± 5 Myr (1σ). The uncertainty has been adjusted to include the scatter which slightly exceeds analytical limits ($S/(n-2)=4.7$ where S is the sum of the squares of the deviation and n the number of points). The data point for the Arkona-shale pyrite from the brachiopod lies significantly below the isochron, indicating a different age and/or source for this Pb. By contrast, authigenic pyrite from a coral (Ark-10s) falls on the least radiogenic end of the isochron indicating that this sulphide is cogenetic with the calcite phases and the other corals. We infer from this relationship that adequate ranges in μ values exist and a precise age may be obtained from a single specimen of coral. The value for sample Ark-8 also falls below the isochron. This sample has an anomalously high value of Pb (1.2 p.p.m.) and is correlated with a relatively large amount of visible pyrite in this coral. The simplest explanation for this point is that there has been an addition of Pb to the coral in the form of pyrite of a composition similar to that of the brachiopod.

An isochron for the same points using the ^{235}U–^{207}Pb decay scheme (data not shown) gives a less precise age of 427 ± 57 Myr (1σ). Despite the poor precision which is a result of the lack of enrichment in radiogenic ^{207}Pb, the age is concordant with the ^{238}U–^{206}Pb age. Thus, as the isochrons are preserved and both ages agree, the U-Pb system in the corals has remained closed with respect to parent and daughter isotopes.

The Devonian of Southern Ontario

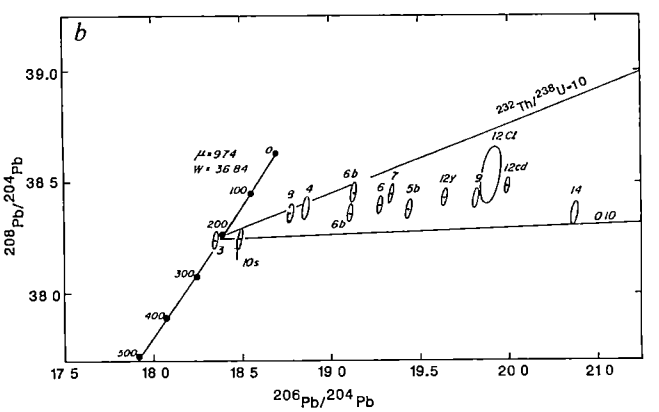

FIG. 2 *a*, Pb-Pb isotope correlation plot for corals, rocks and pyrite from brachiopod from formations of the Arkona area. Uncertainty ellipses are given at the 95% confidence level Initial Pb isotopic ratios for the corals are indicated with a cross Reference curve from ref 16. *b*, $^{208}Pb/^{204}Pb$ – $^{206}Pb/^{204}Pb$ correlation plot for Arkona corals. Straight lines show $^{232}Th/^{238}U$ values of 1 0 and 0 1. Reference curve is from ref 16

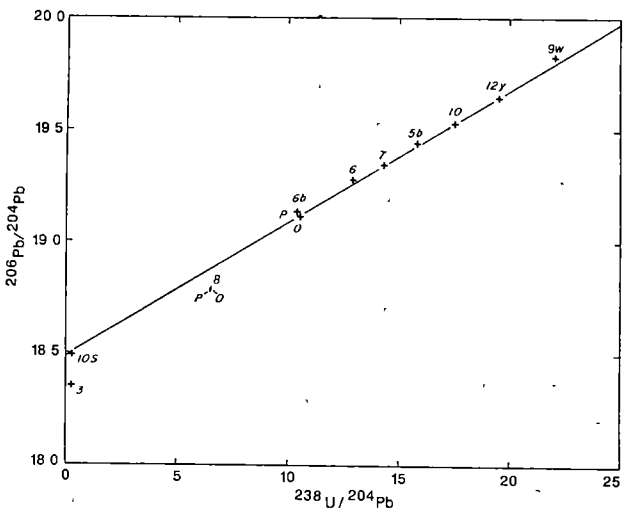

FIG 3 ^{206}Pb–^{238}U isochron plot for the corals giving an age of 376 ± 5 Myr Ark-8 (shown in duplicate) was not used in the regression of the points Ark-3 represents the pyrite analysis from the brachiopod from the Arkona shale

By contrast to the *Heliophyllum* corals, the specimen of *Cystiphylloides* shows some age discordance. The data point for the bulk sample (Ark-12w) lies well above the ^{238}U–^{206}Pb isochron (data not shown). This coral has a much more porous structure and has numerous air pockets that are lined with large amounts of sparry calcite. This calcite (Ark-12sp) has very low U and Pb concentrations — 6.8 and 21.3 p.p.b., respectively. The data point for this sample as well as that for micrite (Ark-12cd) also lie above the isochron. However, data for yellow ferroan calcite (Ark-12y), peculiar to this specimen, lies on the isochron. The U–Pb system of the latter calcite is closed, possibly because it was not in contact with any air pockets. The spaces may have facilitated movement of fluids concomitant with calcite recrystallization long after burial and initial closure of the U–Pb system.

The U and Pb contents from limestones from enclosing strata are 0.35–0.80 and 1.6–3.1 p.p.m., respectively. These values are much higher than the averages of these elements in the corals, and are within the range of limited data from other Phanerozoic limestones[2,13]. The isotope data for the limestones from Arkona indicate that they had slightly lower initial ratios of $^{208}Pb/^{204}Pb$, $^{207}Pb/^{204}Pb$ and $^{206}Pb/^{204}Pb$.

Figure 2*b* shows a plot of $^{208}Pb/^{204}Pb$ against $^{206}Pb/^{204}Pb$. The data for the corals form a trend having a very shallow slope indicating that they have very low $^{232}Th/^{238}U$ ratios. This is a reflection of the low enrichment of Th in the rocks and implies that there is insufficient enrichment in ^{208}Pb to date the corals using the ^{232}Th–^{208}Pb system.

The isochron age of 376 ± 5 Myr compares very favourably with the boundaries which range from 385 to 375 Myr inferred for Givetian strata[14]. An idea of the relative timescale for the diagenetic alteration of the corals is provided by a trace element and stable isotope study[15]. Based on the similarity of ^{18}O values in texturally well preserved (primary) brachiopods and texturally altered corals it was concluded that contemporaneous sea water was the predominant component of the diagenetic fluids affecting these sediments. Thus, it seems that diagenesis occurred and the U–Pb systems in the corals became closed soon after deposition of the host sediments.

The initial Pb ratios derived from the isochron plots allow a characterization of the source of Pb in these corals. Figure 2 shows that both initial $^{206}Pb/^{204}Pb$ and $^{208}Pb/^{204}Pb$ ratios are relatively radiogenic compared to those ratios predicted by an average Earth growth curve at 376 Myr (ref. 16). These isotope patterns are similar to marine pelagic sediments[17] and both signatures reflect the high U/Pb and Th/Pb ratios of the upper continental crust.

Closed-system U–Pb behaviour in whole rocks and minerals is comparatively rare. Discordance is usually attributed to the mobility of U, and less frequently Pb, under surface and subsurface conditions[18,19]. Compared to the material tested in those studies the corals have concentrations of U and Pb that are

Hydrogen-isotope evidence for extrusion mechanisms of the Mount St Helens lava dome

Steven W. Anderson & Jonathan H. Fink

Department of Geology, Arizona State University, Tempe, Arizona 85287-1404, USA

FROM October 1980 to October 1986 the dacite lava dome at Mount St Helens grew through the accumulation of more than 15 separate lobes during extrusive episodes that lasted from 1 to 24 days, except for an anomalous period of continuous growth throughout most of 1983[1]. Over these six years, the growth rate was generally volume predictable; that is, the amount of lava added to the dome in a given eruption was roughly proportional to the time since the preceding extrusion[2]. These well documented eruptions were separated by repose intervals lasting from several months to more than a year[2]. In an attempt to identify the triggering mechanisms for these periodic eruptions, we have used hydrogen isotope analyses to determine water content and deuterium content for 18 samples of the Mount St Helens dome dacite. These isotope data, the first ever collected from an active lava dome, suggest a steady-state process of magma evolution combining crystallization-induced volatile production in the chamber with three different degassing mechanisms: closed-system volatile loss in the magma chamber, open-system volatile release during ascent and kinetically controlled degassing upon eruption at the surface. The data suggest that future dome-building eruptions may require a new influx of volatile-rich magma into the chamber.

Hydrogen isotope analyses of samples from Mount St Helens can be used to investigate the role of changing water content and isotopic composition in eruption processes because both the bulk chemistry and crystallinity have remained essentially unchanged throughout the growth of the dome and because only small amounts of hydrous minerals are present in the lava[3]. We collected surface samples from various positions on the May 1985 and May 1986 lobes and also obtained samples from seven earlier lobes collected by D. Swanson, K. Cashman and C. Heliker of the U.S. Geological Survey (Table 1). The texture of each sample and the date and position relative to the vent and flow front are given in Table 1. There are two distinct lava textures at Mount St Helens. Smooth lava has <30% bubbles compared to >50% for scoriaceous lava, which tends to occur as a 2-3 m thick carapace[4].

Crushed samples were heated to 1,000 °C for 3 h and the water content (Table 1) measured with a manometer (0.002 wt % uncertainty—S. Roberts, personal communication). Hydrogen was produced by the reaction of the expelled water with uranium. The uncertainty in the δD_{SMOW} values is 2‰ (δD_{SMOW} is $\{[(^2H/^1H)_{sample}/(^2H/^1H)_{SMOW}]-1\}\times 10^3$ where SMOW is standard mean ocean water). For comparison, meteoric waters taken from springs in the Mount St Helens area have δD values ranging from −82.3 to −111.4‰, and water from a pond in the summit crater in March 1980 had a δD value of −89.8‰ (ref. 5).

One purpose of sampling several different lobes was to identify temporal trends in water content and isotopic character. We found large variations within individual extrusions, however, making simple inter-lobe comparisons difficult to interpret. We therefore grouped samples by texture (smooth or scoriaceous) and position on the flow (near vent or flow front) in an attempt to compare lavas that had undergone similar degassing histories. This reclassification into four subsets (vent smooth, front smooth, vent scoria and front scoria) showed several trends: (1) for samples from a given flow position, scoria consistently had lower water contents than smooth lava; (2) for a given texture, flow-front samples had lower water contents than near-vent samples; and (3) smooth lava from near the flow fronts had higher δD values than from near the vent.

We have tried to correlate the δD data in Table 1 to various eruptive parameters[2,4] such as lobe volume, underlying slope, ratio of endogenous to exogenous growth and repose period. Because we were interested in processes occurring at depth, we concentrated on smooth samples, as these had apparently been affected less by degassing at the surface[4]. These comparisons revealed one clear trend (Fig. 1): the longer the interval between eruptions, the more deuterium enriched the smooth lava.

Previous isotope studies of volatiles in silicic lavas[6-8] have identified three different degassing mechanisms. Under closed-system conditions, most volatiles lost from the magma remain in contact with the magma and so continue to interact with it, leading to a gradual decrease in δD as water content decreases[6]. Open-system degassing occurs when expelled volatiles are able to escape, causing a more rapid drop in δD with water loss[7,8]. When water contents become extremely low, however, kinetic effects prevent HDO from escaping more rapidly than H_2O, so that there is actually an increase in δD with decreasing water content[8]. In the following scenario, we suggest that all three mechanisms operated during eruption and emplacement of the Mount St Helens dome lavas.

We start with the assumption that between eruptions, the top of the magma body slowly loses volatiles, some of which make

May 1986	5HCS786	Smooth	Flow front	0 111	−43
May 1986	9HCS786	Smooth	Mid-flow	0.271	−67
May 1986	14VC786	Smooth	Mid-flow	0.337	−40
May 1986	11HCS786	Scoria	Near vent	0.149	−46

their way into the eruptive plume over the dome[9]. Although a small fraction of these volatiles escape from the top of the magma body, we feel that this drying out at depth will follow a closed-system fractionation trend, similar to that proposed for some rhyolitic magmas[10,11]. We assume that all of the eruptions are ultimately caused by the steady-state production of volatiles during crystallization of anhydrous minerals in the magma[12,13]. When the resulting buoyancy becomes sufficient, the magma body begins to rise, pushing its dry cap through the conduit to the dome surface. As it works its way upward, the magma loses volatiles more rapidly through fractures in the conduit walls and dome, leading to open-system degassing[7]. When the volatile content has decreased to approximately a few tenths of one percent, kinetically controlled degassing ensues. The extrusion continues until all of the buoyant magma has risen to a new equilibrium configuration. These changes in degassing behaviour cause the δD ratio of any particular magma batch to follow a complex path similar to that represented schematically in Fig. 2.

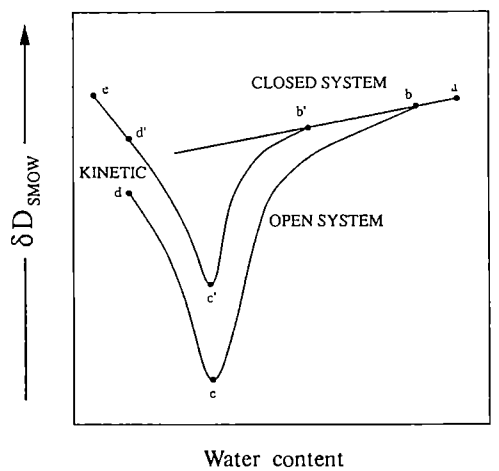

FIG. 2 Schematic diagram showing proposed three-stage degassing curves for two different dome-building eruptions at Mount St Helens Both batches of magma begin with δD and water contents indicated by point *a* The first batch has a short repose period and then follows path *b*–*c*–*d* as it rises to the surface and erupts. The second batch has a longer repose and then follows path *b*′–*c*′–*d*′. Note that the longer hiatus leads to higher δD values for a given water content Point *e*′ represents a hypothetical sample of smooth lava collected from the flow front of the second extrusion which would have travelled further at the surface than a smooth lava sample from near the vent area, *d*′

The slopes of the closed- and open-system fractionation paths in Fig. 2 are arbitrary, because the fractionation factors are not known for Mount St Helens dacite and we also have no data on which to base a starting point. We expect that these factors would depend only on magma composition, however, and thus would not have changed appreciably during the six-year emplacement of the dome. Similarly, the critical water content below which kinetic effects appear is probably independent of time. Thus if different batches of magma had different repose periods before they began their ascent, they subsequently would follow roughly parallel curves on a plot of δD as a function of H_2O.

Consider the magma body before two different eruptions, as depicted by the curves on Fig. 2. In both cases, when the preceding eruptive episode ends, the water content and δD values of the magma are represented by point *a*. Each batch then follows the closed-system degassing path until buoyancy causes the magma to rise. In the first case this point *b* is reached after a hiatus of 50 days, whereas the second batch takes 150 days and enters the open-system portion of the path having a lower water content *b*′. During ascent, the first batch will reach the point *c*, at which kinetic effects begin, with a lower δD value than the second batch *c*′. If both come to rest in the same dome position (near the vent for example), then they will have undergone similar amounts of kinetically controlled degassing, and the magma with the longer repose period will have a higher δD value *d*′. Within each batch, the portion that reaches the flow front *e*′ will have degassed longer and would thus have a higher δD (and lower water content) than the near-vent portion *d* (ref. 4).

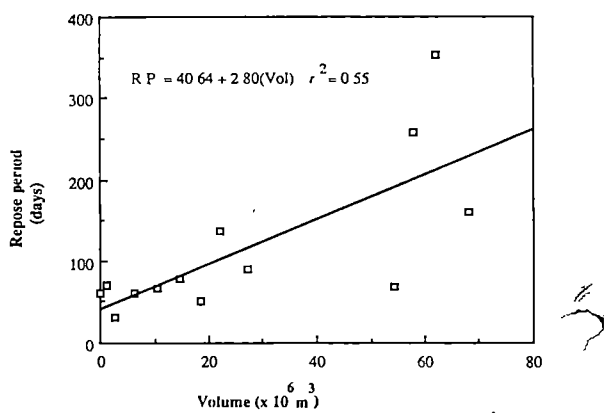

FIG. 3 Repose period as a function of dome volume ($\times 10^6$ m^3) for Mount St Helens extrusions. Volumes used[2] are those of the dome before a given repose period. Volume before October 1980 is assumed to be zero.

Our model accounts for observed δD variations, but does not explain why repose periods vary. If we compare repose duration with dome volume, however, we find a fairly good correlation (Fig. 3) which suggests that as the dome grows, more buoyancy is needed to overcome the increased lithostatic load. Thus if eruptions are driven by a steady-state process such as crystallization-induced volatile production, the greater weight associated with an increase in dome volume will require a longer time for the critical buoyancy to be generated. Other predictable factors such as earth tides[14] or melting of snowpack in the crater[15] can facilitate the eruption process but by themselves are of insufficient magnitude to serve as triggers. On the other hand, the influx of new volatile-enriched magma into the chamber from a deeper source, as is thought to have occurred in March 1982[16], could enhance the buoyancy and lead to a new eruption.

This view of dome growth allows certain predictions to be made about future activity. If the trend shown in Fig. 1 were continuing today and a new eruption were to begin in October 1989, for example, then the three-year (1,095 days) hiatus would suggest that the smooth lava that came out and reached the flow front would be extremely enriched in deuterium ($\delta D = \approx 30‰$). At the same time, the volume of the dome after the October 1986 eruption indicates that the following hiatus should have been around 230 days, leading to an eruption in June 1987. The failure of magma to appear at that time suggests that some other factor was involved, such as the completion of crystallization or the development of a yield strength in the steadily drying magma body. The resumption of eruptive activity may require the influx of a new batch of volatile-rich or crystal-poor magma. □

Undercrusting by serpentinite beneath rifted margins

THE west Galicia passive margin (Spain) is bounded by a continuous belt of serpentinized peridotite. Here we present the results of petrological studies of the peridotite, ^{39}Ar–^{40}Ar dating of high-temperature ductile shearing of a dioritic dyke crossing the peridotite and regional seismic stratigraphy which demonstrate that the uplift, ductile shearing and pervasive serpentinization of mantle rocks occurred at early Cretaceous time, during the rifting stage of the margin. The serpentinite layer resting on fresh peridotite is probably several kilometres thick. At present seismic data and gravity data cannot distinguish serpentinite from crustal material, but our results from the Galicia margin indicate that the seismic crust beneath rifted margin may include mantle material transformed into serpentinite by syn-rift hydrothermal activity. In some cases, this undercrusting process might explain the young age and mobility of the Moho beneath stretched continental basement.

The west Galicia margin, Spain (Figs 1, 2) is a passive margin, formed during a Berriasian/latest Aptian rifting episode (140–114 Myr BP). Recently, it was investigated by DV *JOIDES Resolution* (Ocean Drilling Program Leg 103)[1,2] and the French submersible *Nautile* (Galinaute cruise)[3]. Westward, at the continent-ocean boundary in the Atlantic Ocean, the basement beneath the sediments forms a ridge (Fig. 2) surveyed by reflection seismics[4] for ~130 km (Fig. 1). At its southern part, the ridge strikes N–S parallel to the trend of the tilted fault blocks of the margin. North of 43° N, it turns eastward along the northwestern edge of the Galicia Bank. Its eastern flank is partly buried under lower Cretaceous syn-rift sediments (Fig. 3), indicating that it had formed before sea-floor spreading started.

The ridge consists of highly serpentinized (up to 90%) peridotite, at places replaced and crosscut by calcite veins[5–10]. The peridotites are mylonitic spinel- and plagioclase-bearing harzburgites or lherzolites that underwent limited melt extraction (<10%)[6,7]. At dive site 10 (Fig. 1), the ultramafic is crosscut by a several-centimetres-thick dioritic dyke, containing plagioclase, brown amphibole and ilmenite. This dyke, as well as the peridotite, underwent ductile shearing at high temperatures (>750 °C) and large differential ($\sigma_1 - \sigma_3$) stresses (>1 kbar), and now displays a mylonitic foliation sub-parallel to that observed in the surrounding rock[9]. In the diorite, all the primary magmatic brown amphiboles have recrystallized into millimetre-sized grains during the shearing process. Some crystals, ~3 cm in size, however, grew at the expense of the fine-grained neoblasts at the end of the shearing.

Using the ^{39}Ar–^{40}Ar method we dated large post-tectonic crystals of brown amphibole[11], fine-grained syn-tectonic amphibole and syn-tectonic plagioclase neoblasts. The post-tectonic amphiboles provided a plateau age of 122 ± 0.3 Myr (Fig. 4), corresponding to a constant K/Ca ratio (proportional to $^{39}Ar_K/^{37}Ar_{Ca}$) similar to the microprobe-measured ratio. The fine-grained amphibole provided a scattered age spectrum (see Fig. 4) with concordant high-temperature ages that are nearly consistent with the plateau age of the post-tectonic amphibole. The plagioclase has a saddle-shaped age spectrum which is characteristic of excess argon. The weighted mean of 117.7 ± 0.9 Myr (calculated on the 700–1,080 °C steps) may represent a maximum estimate. Although the plagioclase crystallized before the post-tectonic amphibole, these results are concordant with the cooling history of the diorite, the closure temperature below which all radiogenic ^{40}Ar is trapped within the mineral of the amphibole being higher than that of the plagioclase. We therefore conclude that the 122.0-Myr age corresponds to the end of the ductile shearing of the dioritic dyke. Because the ductile deformation of the dioritic dyke and that of the surrounding peridotite occurred under a similar strain regime and physical conditions, we consider that this age is also that of the emplacement of the peridotite near the surface of the lithosphere[11].

This result indicates that uplift and emplacement of ultramafic

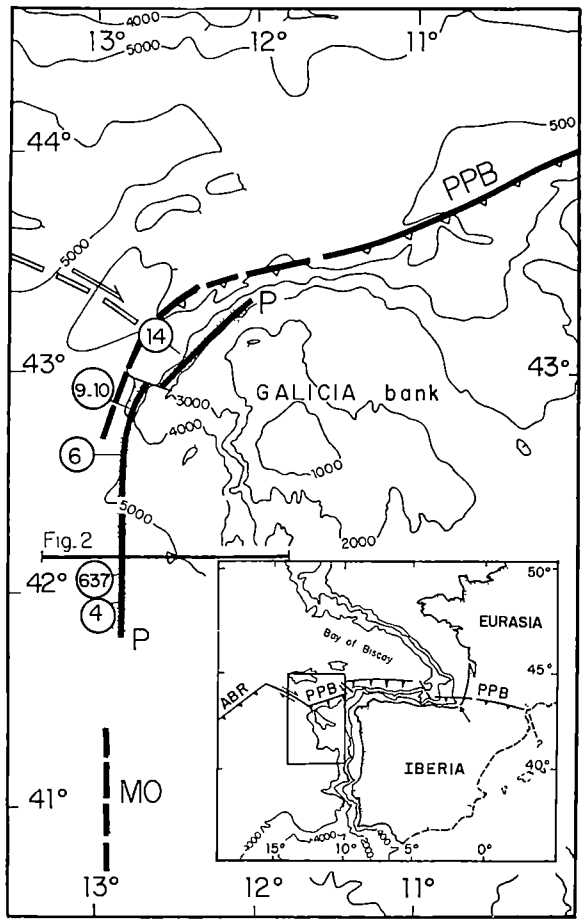

FIG 1 Location of drill site 637 (ODP Leg 103[1,2]) and dive sites 4, 6, 9–10 and 14 (Galinaute cruise[3]) where peridotite was sampled on the Galicia margin. Bathymetry in metres. MO, MO magnetic anomally[22]; ABR, Azores–Biscay Rise; P, Peridotite ridge, PPB, Palaeocene plate boundary[23]

rocks occurred during the rifting of the margin (140–114 Myr), before the opening of the north Atlantic Ocean between the Iberian and American plates. As the serpentinite is broken by normal faults[7,8] and sealed by syn-rift sediments[4], we assume that most of the serpentinization of the peridotite also occurred during rifting, probably at the latest stage of emplacement of mantle rocks on the sea floor, as a result of the intrusion of sea water within the rock[8].

At present, there are only few other examples of serpentinite belts bounding rifted margins (south Australia margin[12]; Tyrrhenian sea[13]). Usually, the ocean–continent transition is buried under thick sediments preventing from drilling into basement. The west Galicia margin is exceptional in that it is a very starved margin with only a thin and discontinuous sedimentary cover above basement. It is, however, a very typical rifted margin and we assume that the peridotite ridge is representative, although other kinds of ocean–continent transition can occur in the global ocean.

Unfortunately, as seismic refraction data are not yet available on the Galicia margin, the thickness of the serpentinite layer that overlies fresh peridotite is poorly constrained, but it can be roughly estimated. Therefore no noticeable anomalies in a gravity survey of that region[14], so the hypothesis of local isostatic balance is reliable. The ocean is 5,250-m deep, and the sediment thickness ranges from 0 to 2.5 km (ref. 4) assuming a mean density of 2.2 g cm^{-3}. Petrological studies of drilled samples have shown that serpentinization is inhomogeneous and varies from 100% to 60%[6–8]. Accordingly, density would vary from 2.6 to 2.9 g cm^{-3} (ref. 15). In our opinion, a mean density of 2.9 g cm^{-3} seems to be realistic, as serpentinization is expected to decrease at depth. On the other hand, 3.35 g cm^{-3} is a reliable value for the density of fresh peridotite from old lithosphere (>114 Myr). Then, the calculated serpentinite thickness at the ocean–continent transition of the west Galicia margin ranges from ~9 km to ~2.5 km, depending on sediment thickness.

This estimate is not surprising: it is now accepted that sea water can penetrate the upper lithosphere down to several kilometres, and the breakdown of olivine into a serpentinite assemblage[16] is usual at the pressure and temperature conditions expected during rifting beneath the sediments covering the peridotite ridge or beneath the much thinned and faulted continental crust of the deep Galicia margin as well.

Figure 2 shows the possible eastward continuation of the serpentinite layer from the peridotite ridge to the deep margin. This lateral extent may be related to the strong seismic reflector, labelled S, that occurs within the basement of the deep margin. On average, S extends at 5–2 km depth below the layered sedimentary cover[4], deepens landward and seems to intersect the top of the basement between the peridotite ridge and the deepest continental block of the margin[17] (Figs 2 and 3). It may be the seismic signature of the contact between the serpentinite and the continental basement, a place we expect an impedance contrast.

On the west Galicia margin, it seems that: (1) the stretching of the lithosphere during the rifting stage of the margin may result in total removal of the continental crust and unroofing of the mantle at the continental rift axis; (2) serpentinization of the exposed mantle peridotite can occur at several kilometres depth below the sea floor, and the serpentinite layer may extend laterally beneath the very thinned and faulted continental crust of the rift. (3) Serpentinite has a density[15] and seismic velocity[18] comparable to that of the lower continental crust and therefore neither seismic refraction nor the gravity data can be used to distinguish definitely between lower continental crust and serpentinized upper mantle material. However, we think, by analogy with seismic crust of oceanic lithosphere, that the seismic crust of stretched continental lithosphere may comprise serpentinite generated by hydrothermal alteration of the uppermost mantle. We call this process undercrusting to distinguish it from underplating, which relates to upward magma crystallization at the crust–mantle boundary during rifting[19]. Indeed, undercrusting is probably not as important as underplating, as volcanic rocks in continental areas do not often contain serpentinite xenoliths. However, we think that it can play a significant

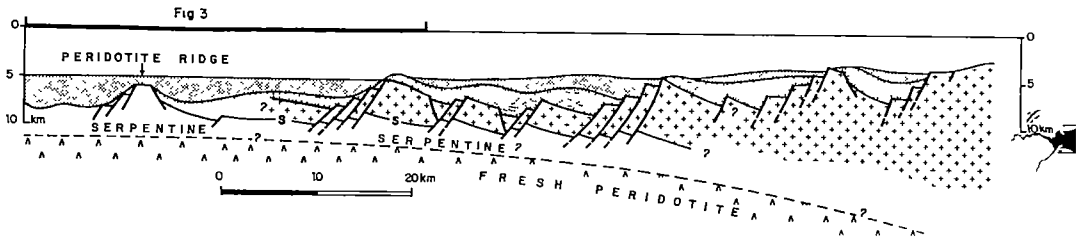

FIG. 2 Synthetic cross-section of the deep Galicia passive margin[17] (location on Fig. 1). The Moho depth is calculated assuming isostatic equilibrium, densities of 2.8 g cm^{-3} for the thinned continental crust, 2.9 g cm^{-3} for serpentinite and 3.35 g cm^{-3} for fresh peridotite M, seismic Moho; S, S seismic reflector[24] assumed to be the contact between serpentinite and thinned continental crust S was faulted at the latest stage of the rifting

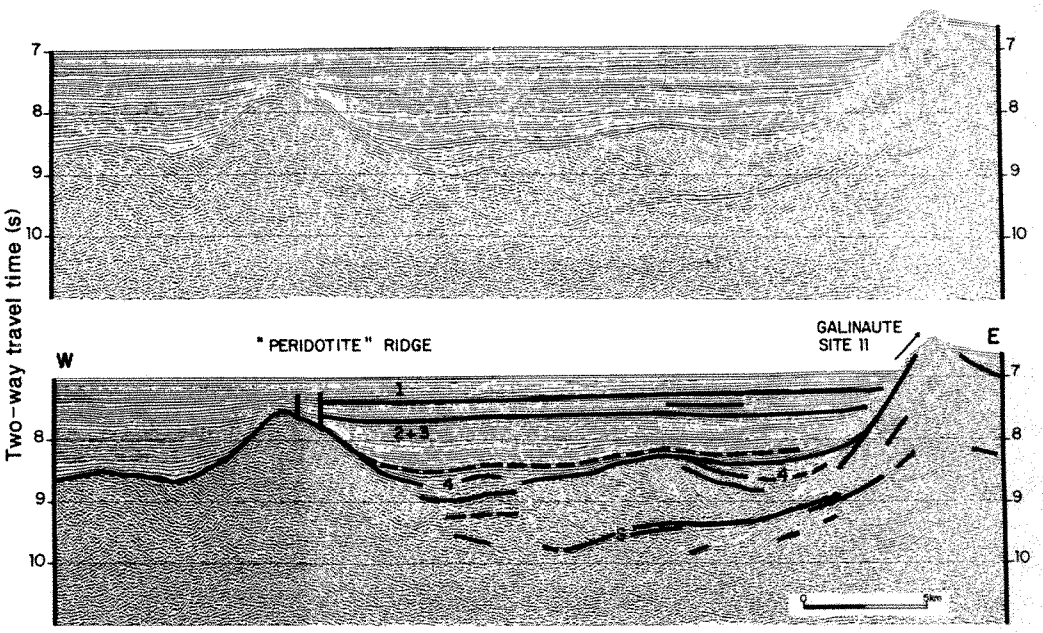

FIG. 3 Seismic line[4] depicting the peridotite ridge and the deepest fault block of the west Galicia margin, where the granodioritic continental basement was sampled[3]. S, S seismic reflector[24]. 1–3, post-rift sediment; 4, syn-rift sediments. See Fig. 2 for location.

part beneath advanced continental rifts. Such an interpretation is supported by the existence of the regional seismic reflector S, mentioned above. (4) Wide-angle reflections at the base of the continental crust indicate that the reflective Moho is relatively young with respect to the age of the upper continental basement and even to several Mesozoic basin formations as well[20,21]. Perhaps this is a consequence of the downward migration of a hydrothermal front and the subsequent serpentinization of fresh peridotite at the top of the mantle, as probably occurred beneath the Galicia continental rift in the Cretaceous. We do not yet know the greatest depth to which water may be introduced in the continental lithosphere and whether layering of lower continental crust may result from inhomogeneous serpentinization of mantle rocks. Lenses of poorly serpentinized peridotite entrapped within highly serpentinized material could account for seismic reflectors at the base of the continental crust in rifted zones. Our suggestions, although based on the unique example of the West Galicia margin, raise important questions relevant to both the mobility of Moho beneath stretched continental basement and the actual nature of the lower continental crust. □

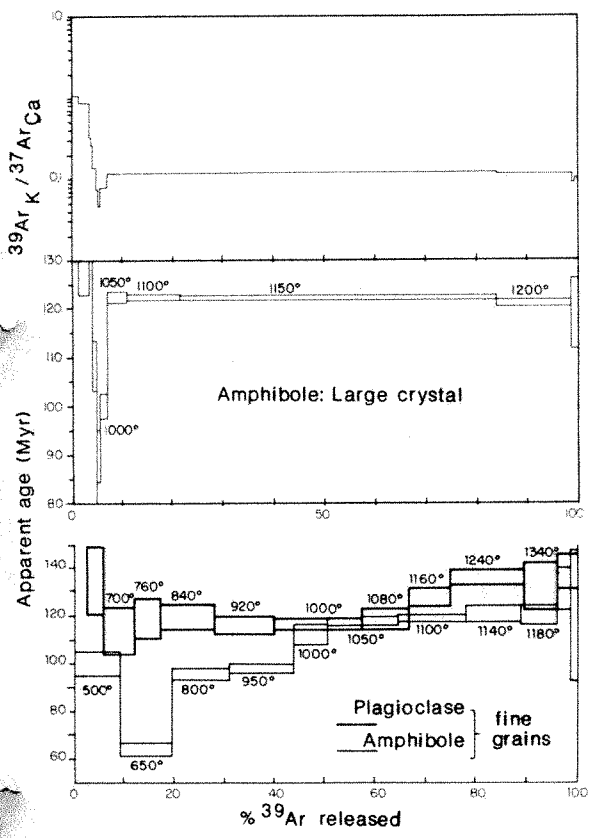

FIG. 4 ^{39}Ar–^{40}Ar age spectra for euhedral undeformed amphibole, fine-grained amphibole and plagioclase sampled in a dioritic vein crossing peridotite at dive site 10. See Fig. 1 for location. Samples were irradiated in the Melusine reactor (CEN Grenoble). The monitor was the biotite LP6 128.5 Myr in age. Uncertainties are at the 1σ level.

The oxidation state of the Earth's sub-oceanic mantle from oxygen thermobarometry of abyssal spinel peridotites

L. Taras Bryndzia*, Bernard J. Wood* & Henry J. B. Dick†

* Department of Geological Sciences, Northwestern University, Evanston, Illinois 60208, USA
† Department of Geology and Geophysics, Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543, USA

THE oxygen fugacity (f_{O_2}), or redox state, of the Earth's mantle is an important parameter in the evolution of mantle-derived magmatic rocks. Most estimates of the upper-mantle redox state have been based on samples of the sub-continental mantle and terrestrial lavas, and estimates of f_{O_2} obtained by thermobarometric methods tend to cluster within ±1.5 log units of the FMQ (fayalite–magnetite–quartz) reference oxygen fugacity buffer[1–3]. Much less is known about the redox state of the sub-oceanic mantle, the ultimate source of mid-ocean-ridge basalts (MORBs). Here we use oxygen thermobarometry of abyssal spinel peridotites, representative of most of the Earth's mid-ocean-ridge systems, to show that the redox state of the sub-oceanic mantle lies at values of up to 4 log units (average of 1.35 log units) more reduced than FMQ. Our results are in excellent agreement with oxygen fugacities of MORBs obtained from Fe^{3+}/Fe^{2+} ratios of quenched glass in pillow basalts[4]. This agreement confirms the redox state of the MORB source region and suggests that MORB glasses (as opposed to the cores of pillow basalts) have not undergone significant oxidation (hydrogen degassing) during their ascent.

We have sampled abyssal spinel peridotites ($n = 33$) from fracture zones along the Central Indian, America-Antarctica, South-west Indian and Mid-Atlantic Ridge systems as well as the Cayman Trough. Although variably affected by hydrothermal alteration, all of our samples contained fresh spinel (sp) and olivine (ol), with most samples also containing orthopyroxene (opx); they are, therefore, amenable to application of the spinel-peridotite oxygen thermobarometer[1–3].

Oxygen thermobarometry is based on the heterogeneous equilibrium

$$2Fe_3O_4\,(\text{in sp}) + 6FeSiO_3\,(\text{in opx}) = 6Fe_2SiO_4\,(\text{in ol}) + O_2 \qquad (1)$$

Fe_2SiO_4 refers to the fayalite component in olivine, $FeSiO_3$ the ferrosilite component in orthopyroxene, and Fe_3O_4 refers to the magnetite component in spinel. The thermodynamic properties of complex $MgAl_2O_4$–Fe_3O_4 spinels have recently been calibrated[1] for the temperature range 900–1,100 °C and spinel compositions common to upper-mantle spinel lherzolites ($0.01 \leq X^{sp}_{Fe_3O_4} \leq 0.10$). As long as compositions of all phases are known, together with appropriate activity-composition relationships, it is possible from available standard-state data to obtain estimates of f_{O_2} at any temperature and pressure[3,5]. Silicate-mineral compositions were obtained by electron-microprobe analysis[6]. Mössbauer-analysed natural spinels of widely variable Cr number (Cr/(Cr+Al)) and $Fe^{3+}/\Sigma Fe$ ratios were used as secondary electron-microprobe standards for spinels. To avoid any possible effects of submarine hydrothermal alteration on the silicate phases, all mineral analyses were made on fused glasses of hand-picked optically clear diopside and enstatite, to homogenize solution lamellae (where present) and to determine a primary composition for these phases[6]. Mineral analyses were also performed on optically clear hand-picked grains of olivine.

We obtained spinel concentrates by digesting samples of abyssal spinel peridotite in 50% (wt%) HF acid, followed by several digestions in 35% (wt%) HCl acid. This ensured the removal of any magnetite–haematite alteration of the spinel. All spinel concentrates were then passed through a Frantz magnetic separator. No magnetic material remained after the HCl-acid treatment and optical examination under reflected light revealed that only a pure spinel concentrate remained. We obtained magnetite contents of spinel by microprobe analyses and also by Mössbauer spectroscopy on the clean HCl-treated samples using the methods described in ref. 3. Mole fractions of Fe_3O_4 in spinels from abyssal peridotites range between 0.006 and 0.047 with a mean of 0.021. The microprobe and Mössbauer methods agree with one another, generally giving results within ±0.003 in $X_{Fe_3O_4}$.

We obtained temperatures of equilibration using an empirical two-pyroxene geothermometer[7]. Not all of our abyssal peridotite samples contained two pyroxenes suitable for geothermometry. For these samples, a mean temperature estimate based on a suite of eleven samples from the America/Antarctica/South-west Indian Ridges was used (1,153 ± 75 °C; $n = 11$, ±1 s.d.). We assumed the fayalite and ferrosilite contents of samples lacking either olivine and/or orthopyroxene to be 0.09, also based on average compositions of these phases in the same suite of eleven abyssal peridotite samples.

We measured oxygen fugacities of abyssal peridotites using equilibrium (1) at an estimated total pressure of 10 kbar. As there is no presently available means of estimating equilibration pressures for spinel peridotites a pressure of 10 kbar was chosen primarily for two reasons. First, the rocks for which we report results here are plagioclase-free spinel peridotites. Second, plagioclase-bearing peridotites have also been reported[6] to occur at several localities along the mid-ocean ridges that we have also sampled. A pressure of 10 kbar at 1,153 °C is in the spinel-peridotite field of stability but also close to the boundary between plagioclase-bearing and spinel-bearing peridotites. The results have been plotted in Figs 1 and 2, as $\Delta \log f_{O_2}$ relative to the calibration of the FMQ-reference f_{O_2} buffer[8], $\Delta \log f^{FMQ}_{O_2}$. Significantly, almost all of the f_{O_2} data are values more reducing than FMQ. Another important feature of the abyssal-peridotite f_{O_2} data is that they seem to be bimodally distributed, with over 80% of our samples lying between $\Delta \log f^{FMQ}_{O_2} = -2.5$ and +1,

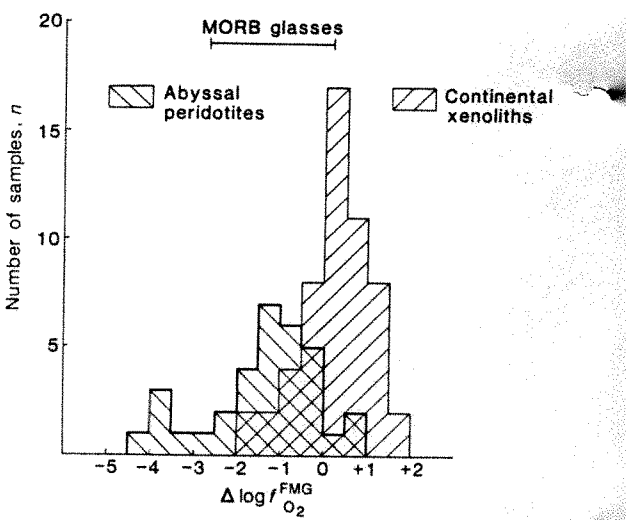

FIG. 1 Calculated $\Delta \log f_{O_2}$ distributions (relative to FMQ) for spinel-bearing abyssal peridotites (this study) and sub-continental mantle spinel lherzolites (unpublished data and ref. 2). The majority of abyssal peridotites lie at f_{O_2} conditions more reduced than FMQ compared to mantle spinel lherzolites which form a tight distribution (±1.5 log units) at FMQ. These data suggest that the sub-oceanic mantle is more reduced than the sub-continental mantle. f_{O_2} data for MORB glasses is from ref. 4 and defines a range in $\Delta \log f_{O_2}$ in excellent agreement with the abyssal peridotite values.

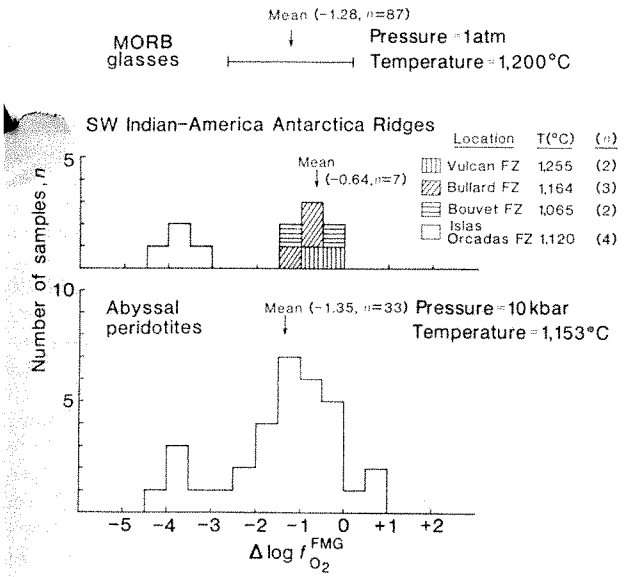

FIG. 2 Δ log f_{O_2} (relative to FMQ) results for abyssal peridotite samples from the America/Antarctica/South-west Indian Ridges in the vicinity of the postulated Bouvet Island hotspot. Note the anomalously reduced nature of abyssal peridotites from the Islas Orcadas fracture zone (FZ) relative to all other samples.

and the remainder being distributed almost exactly at the iron-wüstite (IW) reference buffer ($\Delta \log f_{O_2}^{FMQ} \simeq -3.75$). Four of the six samples close to IW belong to a suite of samples collected from the Islas Orcadas fracture zone near the mantle hotspot present[9,10] in the Bouvet Island area. The results in Fig. 2 suggest that the mantle near the hotspot may be anomalously reduced compared to the mantle beneath mid-ocean ridges in general. Our results show that the upper mantle beneath mid-ocean ridges has a mean $\Delta \log f_{O_2}^{FMQ}$ of -1.35 ± 1.3 ($n = 33$; ± 1 s.d.) with values ranging from near FMQ to IW.

The range of f_{O_2} values observed in continental spinel lherzolites is also given in Fig. 1. Comparison of the two data sets shows that both the mean and range of f_{O_2} values observed in abyssal spinel peridotites are significantly more reduced than those previously reported for continental spinel lherzolites[1-3]. Our results are, however, in very good agreement with f_{O_2} values reported[5] for continental spinel lherzolites from eastern Australia and the south-west United States, based on a different calibration of a spinel oxygen thermobarometer[5]. These results imply a possible genetic link between abyssal spinel peridotites and some suites of continental spinel-lherzolite xenoliths as has recently been suggested[3]. Our data also show that the sub-oceanic mantle is more reduced than has been suggested[11-13]. Values near IW (ref. 11) were obtained by the intrinsic zircon-cell technique on two samples of peridotite. The intrinsic f_{O_2} measurements have recently been shown to be unreliable and in general give f_{O_2} values considerably more reduced than are obtained using other techniques[14].

The redox states of a large ($n = 87$) and geographically diverse suite of MORBs showed[4] that the Fe^{3+}/Fe^{2+} ratios of pillow cores give f_{O_2} values in the range FMQ-NNO (nickel/nickel oxide f_{O_2} buffer) in agreement with subaerial basalts. Fe^{3+}/Fe^{2+} ratios of rapidly quenched glasses from the pillow margins, however, indicated f_{O_2} values 1 to 2 log units below FMQ. These results suggested that the MORB source regions are more reduced than FMQ and that lavas must oxidize rapidly during cooling, possibly by loss of hydrogen. The MORB data of ref. 4 therefore placed constraints on the upper limit for the redox state of the MORB source region. Those results have been plotted on Figs 1 and 2 to facilitate comparison with the abyssal peridotite data. The mean $\Delta \log f_{O_2}^{FMQ}$ is -1.28 ± 0.63 ($n = 87$; ± 1 s.d.), a result in excellent agreement with our thermobarometric estimate for the redox state of the MORB source region. The agreement between the f_{O_2} values indicated by MORB glasses and the abyssal spinel peridotites suggest to us that the MORB glasses (as opposed to pillow cores) have not undergone any significant oxidation or degassing. Hence, we conclude that the data from abyssal spinel peridotites confirms the redox state of the sub-oceanic mantle and the MORB source region as determined in ref. 4. There is considerable uncertainty as to whether pressure has a significant affect on the Fe^{3+}/Fe^{2+} ratio[15-17] and the f_{O_2} that such a ratio represents. Because of the uncertainties associated in estimating the $\Delta \log f_{O_2}$ variations as a function of pressure-related changes in Fe^{3+}/Fe^{2+} ratios, we prefer, at present, to accept the results of experiments that were conducted with basaltic liquids and in which f_{O_2} was a controlled variable[15], a condition not satisfied by the other studies[16,17]. The pressure effect on the Fe^{3+}/Fe^{2+} ratio in basaltic liquids (1 bar–10 kbar) is negligible[15]. We have therefore made no pressure correction to the f_{O_2} values indicated by the MORB glasses in Figs 1 and 2. The agreement between f_{O_2} estimated for the MORB glasses and abyssal spinel peridotites may be taken to indicate that the pressure effect on Fe^{3+}/Fe^{2+} ratios, if real, is quite small, consistent with ref. 15. □

PSEUDOSCORPIONS (Class Arachnida; Order Pseudoscorpiones) represent a diverse and abundant group of small predatory arthropods[1–4]. Approximately 3,000 living species occupy habitats ranging from sea level to 5,000 metres elevation. Until now, the fossil record of the group extended back only 35 million years, to the Oligocene, where nearly 30 species, all in extant families, have been described from the Baltic Amber[5]. Addition pseudoscorpions have been described from the younger Dominican[6] and Mexican[7] ambers, and they too are all assignable to modern families. We now report the discovery of two pseudoscorpion specimens in Middle Devonian sediments near Gilboa, New York, USA. This

* To whom correspondence should be addressed.

find increases the documented age of the order more than 10-fold to ~380 million years. Although the specimens cannot be assigned with certainty to any extant superfamily, their excellent state of preservation allows us to make numerous inferences concerning behaviour and ecology, such as silk use, grooming and tactile behaviour. The presence of certain well preserved structures indicates that Devonian pseudoscorpions were predatory, as are their modern counterparts. Our discovery provides further evidence that fully terrestrial arthropods coexisted with primitive vascular plants during the Middle Devonian.

Middle Devonian sediments near Gilboa in New York State have yielded an abundant and diverse fauna of terrestrial arthropods[8], including extinct groups such as trigonotarbids[9] and arthropleurids, as well as the earliest representatives of groups still living, including centipedes[10], oribatid mites[11] and spiders[12]. To the latter list we can now add pseudoscorpions; the discovery of two specimens of this order increases the documented age of the group by more than 10-fold, to ~380 million years. Significantly, the Devonian fossils already possess all major apomorphies of the order, but in a combination not known from any surviving clade of pseudoscorpions. As with the other Gilboa fossils, the two pseudoscorpions were extracted by hydrofluoric acid maceration from a black shale rich in plant remains. The appearance of the fossils, their authenticity, and the methods by which they are studied have been discussed in detail[9].

The more complete of the two specimens (Fig. 1) is ~0.76 mm in its widest dimension, and 0.45 mm long. The specimen includes both chelicerae, one complete and one partial pedipalp, both first legs and parts of other legs, and the first four or five abdominal segments. The excellent preservation has allowed us to see such details as the many specialized structures of the chelicera (see below), the distribution of trichobothria on the palpal chela, and the pattern of jointing of at least the first leg, all important for systematic assignment.

The second specimen is from a larger animal and consists only of a single pedipalp chela and a single chelicera; the specimen is ~0.72 mm long, indicating that the animal from which it came would have been about twice the size of the first specimen. If anything, the preservation of this specimen is better than that of the first, allowing at least the palpal chela and the chelicera to be fully compared with the same structures of living species.

The complex adaptations of the chelicerae of pseudoscorpions are characteristic of the order[1] and are all clearly present in the fossils. The chelicera consists of two parts, a large basal one with a fixed finger, and a distal one which acts as a movable finger. In nearly all pseudoscorpions, including the Devonian fossil forms, the ventral surface of the basal part bears a group of modified setae called a flagellum (f in Fig. 3); the function of this structure is not known. The fixed cheliceral finger exhibits a broad, transparent toothed structure known as the serrula interior (si in Fig. 3), used in grooming. Ventral on the movable finger is a similar structure, the serrula exterior (se in Fig. 3), also for grooming and cleaning the other appendages[4]. The movable finger has an apical galea (g in Fig. 3), or spinneret, which, when present in living forms, produces silk used to construct moulting and resting chambers[4].

The pedipalps of pseudoscorpions are chelate, an adaptation which causes them to resemble true scorpions, to which they are only distantly related[13]. In many living clades of pseudoscorpions, venom glands are present in one or both chelal fingers; we could not detect a venom apparatus in either of the fossil specimens. The pedipalps are also important sensory organs. Pseudoscorpions have small eyes which are presumably of little use in their dark habitats, and locate prey primarily by touch or by the perception of airborne vibrations[3]. These stimuli are picked up by highly modified sensory hairs on the pedipalps called trichobothria. Trichobothrial hairs, extremely thin and delicate, have not been preserved on the fossils, but the bothria, the characteristic sockets from which the hairs extend, are present (b in Fig. 2). The distribution of these sense organs is of great significance in pseudoscorpion systematics[1,2], and in the study of their postembryonic development[1].

The location and number of palpal bothria indicates that both our specimens represent juvenile instars, and that the smaller may be a first post-hatching, or protonymphal, instar, because it has only a single bothrium on the movable finger of the chela. The larger specimen, with three bothria, may be a last-instar juvenile, or tritonymph, one moult preceding sexual maturity[1]. Though modern pseudoscorpions have four post-hatching instars[4], we of course do not know if this was the case in the Devonian. We also do not know if our specimens represent moulted cuticles or actual carcasses, but the delicate nature of the material indicates the former.

Because the specimens are obviously from different instars, we can express no opinion on their conspecificity. As to further systematic placement, Table 1 compares characters of both fossils (not all the listed characters can be seen on each specimen) with what we believe to be the two pseudoscorpion superfamilies most likely to be related to the fossils, Chthonioidea and Neobisioidea. We have selected these two superfamilies because of the large chelicerae, two-segmented anterior leg tarsi, and smooth cuticle of the fossils[4]. On the nine listed characteristics, the fossils agree with Chthonioidea in two, with Neobisioidea in five, and differ from both in two instances. If

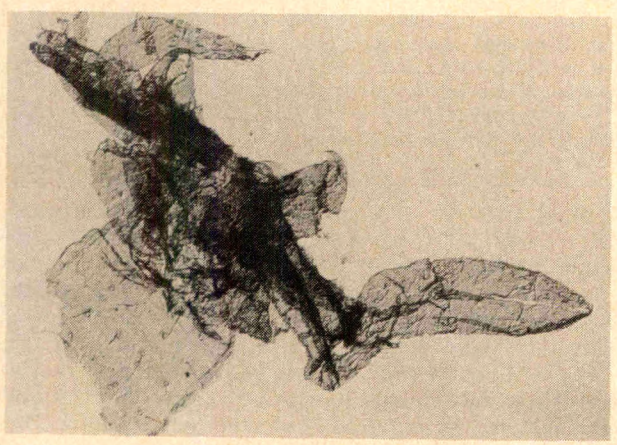

FIG. 1 Specimen of pseudoscorpion protonymph from the Middle Devonian of Gilboa, New York. Slide number 411-19-AR17. Photographed at ×100 on Kodak Technical Pan film using Nomarski differential interference contrast.

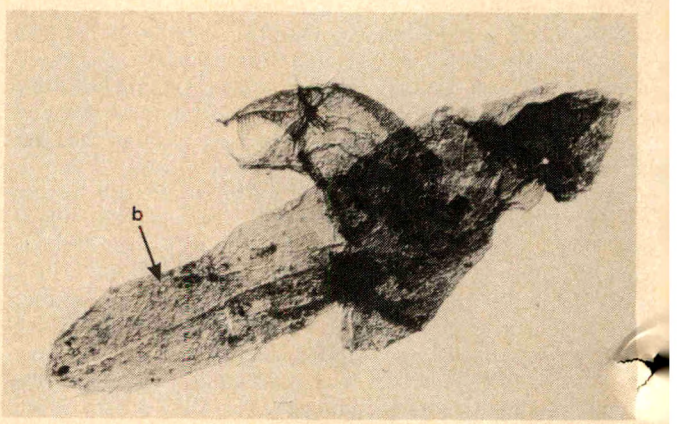

FIG. 2 Palpal chela and chelicera of pseudoscorpion tritonymph from the Middle Devonian of Gilboa, New York. Slide number 411-19-AR9. Method as for Fig. 1; b, bothrium (see text).

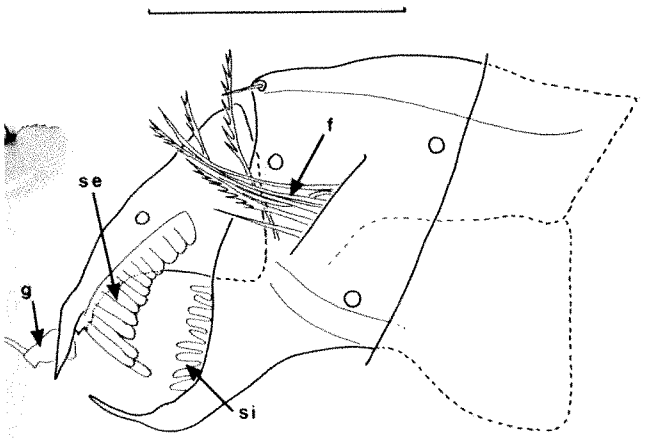

FIG. 3 Interpretive drawing of tritonymph chelicera. Key: f, flagellum; g, galea; se, serrula exterior; si, serrula interior. Scale bar, 0.1 mm.

he larger fossil is indeed a tritonymph, it already has a larger number of fixed finger bothria (six plus two) than the adult of any known living species. Smooth serrula interior blades are found in adults of some living species, but to our knowledge, not in any adult chthonioids or neobisioids. More detailed study of these specimens, now in progress, may reveal further details clarifying their relationship to living forms.

Cladistic methods have yet to be applied to the study of pseudoscorpion phylogenetics, so we are not able confidently to assign polarities to any of these characters. But the Devonian fossil pseudoscorpions probably cannot be placed in an extant superfamily.

The preservation of details in the fossils also allows us to make some inferences about the autecology and behaviour of Devonian pseudoscorpions. The presence of a galea establishes this early date for silk use by the group. Devonian pseudoscorpions also groomed themselves using cheliceral serrulae. The structure of the palpi and chelicerae tells us that Devonian pseudoscorpions were predators, like their modern relatives. But they may not have had a palpal venom apparatus. A rich complement of palpal trichobothria is significant, because it means that touch and airborne vibrations were important to the Devonian species, and that they were fully terrestrial, because trichobothria cannot function in water[14]. We were not able to find spiracles, which normally occur on the third and fourth sternites, in the more complete of the two fossils. The thin, ungranulated cuticle of the specimens is characteristic of modern pseudoscorpions from humid biotopes.

It is significant for arachnid evolution that the existence in the Devonian of modern-looking pseudoscorpions also implies that their sister group, the Order Solifugae[13], was also present. The single known Palaeozoic solifuge is from the Upper Carboniferous of Mazon Creek, Illinois, USA[15].

In the larger scheme of the evolution of terrestrial arthropods, these specimens are important because they establish, as has already been done by Gilboa fossils for centipedes[10], two major clades of mites[11,16], and spiders[12], that fully terrestrial arthropods of modern aspect coexisted with the primitive vascular land plants of the Middle Devonian. Arthropods may have preceded vascular plants on to land, and algal or cyanobacterial mats may have served as major primary producers in the early evolution of terrestrial ecosystems. □

TABLE 1 Comparison of fossils with two living superfamilies

Character	Fossils	Chthonioidea	Neobisioidea
Cheliceral flagellum	Row of setae	Cluster of setae	Row of setae
Distinct galea	Present	Absent in most	Present in many
Blades of serrula interior	Smooth	Denticulate in adults*	Denticulate in adults*
Number of bothria on palpal fixed finger	6+2†	4+2	6
Number of bothria on palpal hand	0	2	0
Teeth of palpal chela	Narrow, inclined	Mostly acute, well-separated	Mostly narrow, inclined
Tarsus of leg 1	Biarticulate‡	Monoarticulate	Biarticulate
Subterminal tarsal seta	Acute	Acute	Modified*

* Condition in early instars not known for certain.
† Count from suspected tritonymph; '6+2' refers to six bothria distributed along the finger and two adjacent ones close to the tip.
‡ Observable only on suspected protonymph.

ACKNOWLEDGEMENTS. This work was supported by NSF grants to W.A.S. and P.M.B., and by a grant to P.M.B. from the Power Authority of New York State. The visit of W.S. to the USA to study the material was partially supported by the Staatliches Museum für Naturkunde, Stuttgart. We thank Andrew Robble, who prepared the specimens and first recognized them as important, and William B. Muchmore, who commented on the material at an earlier stage in our work. We also thank Paul Selden for comments on the manuscript.

A possible neuronal basis for Doppler-shift compensation in echo-locating horseshoe bats

Walter Metzner*

Zoologisches Institut, Luisenstrasse 14, D-8000 München 2, FRG

THE auditory system of the horseshoe bat is finely tuned to the bat's individual vocalization frequency[1,2]. To compensate for flight-induced Doppler shifts in the echo frequency, the horseshoe bat adjusts the frequency of its echo-location call to maintain the echo frequency within the narrow range to which its auditory system is best tuned[3,4]. In this report I describe neurons in the midbrain tegmentum of the horseshoe bat, with properties that strongly indicate their involvement in this Doppler-shift compensation. The activity of these neurons was influenced by both sound emission and auditory stimuli. Neuronal discharges in response to vocalization, however, differed from those in response to purely auditory stimuli that mimicked the bat call. When an auditory stimulus was temporally locked to a preceding vocalization, the response was dependent on the time delay between the two. This delay-sensitivity completely disappeared when vocalizations were simulated acoustically. Only those vocalization and 'echo' parameters

* Present address: Neurobiology Unit, Scripps Institution of Oceanography, University of California at San Diego A-002, La Jolla, California 92093, USA.

were encoded that occur in Doppler-shift compensation[5–7]. In conclusion, I suggest a model for the regulation of the vocalization frequency through auditory feedback.

The horseshoe bat emits long constant-frequency echolocation calls (VOC), which are of a stable individually specific 'resting frequency' when the bat is stationary[2,3]. The resting frequencies of rufous horseshoe bats (*Rhinolophus rouxi*) are ~78 kHz. The bat's auditory system is tuned to a narrow frequency range ('auditory fovea') of 100–200 Hz above the resting frequency[1,8]. Flight-induced Doppler-shifts of only a few hundred hertz remove echo frequencies from the auditory fovea. To maintain the Doppler-shifted echo within this foveal range, the horseshoe bat lowers its VOC frequency below the resting frequency by the amount necessary to compensate for the frequency shift in the previous echo[3]. This Doppler-shift compensation can even be elicited during neurophysiological experiments[9].

I recorded the activity of single units in the midbrain and brainstem of freely vocalizing rufous horseshoe bats. I chose these brain areas because of their proximity both to auditory structures and to structures implicated in vocalization[10–13]. Of 755 units recorded, 189 units, all located rostral and medial to the nuclei of the lateral lemniscus, were active before, during or after vocalization, and also responded to auditory stimuli. These units were termed 'audio-vocal' neurons (AV neurons)[14]. On the basis of its position and connections, the region of these units seems to be homologous to the paralemniscal zone of other mammals[15–18].

All AV neurons were active in the absence of auditory stimuli and vocalization. In 108 units, the background discharge rate increased three- to sevenfold during periods of vocalization. Remarkably, the best frequencies of all but 15 AV neurons were confined to a narrow range between each bat's individual resting frequency and 6 kHz above. This frequency band precisely corresponds to that which evokes Doppler-shift compensation in behaving animals (Fig. 1*a*)[3,6].

Two main classes of AV neurons were found. The first class consisted of 'VOC-inhibitory' neurons (94 of 189 units; Fig. 1*b–f*) that were suppressed during individual vocalization, whereas auditory stimuli with acoustic parameters identical to the vocalization caused sustained excitation. Most strikingly, these units responded dramatically to frequency changes smaller than 100 Hz near their best frequencies, which were in the range between the resting frequency and 5 kHz above. This sensitivity to frequency variations again matches that of the Doppler-shift compensation[1,4]. In addition, the non-monotonic spike-count functions typically showed maxima at sound-intensity levels that correspond to naturally perceived echo intensities[19].

'VOC-excitatory' neurons (95 of 189 units) formed the second class of AV neurons. Before the onset of VOC, 63 of them became active. The remaining 32 neurons were only excited synchronously with the onset and end of VOC, or only after the end of VOC. Auditory stimuli identical to vocalization elicited phasic responses in all neurons. Discharges in 38 of the 63 prevocal-excitatory neurons preceded vocalization by up to

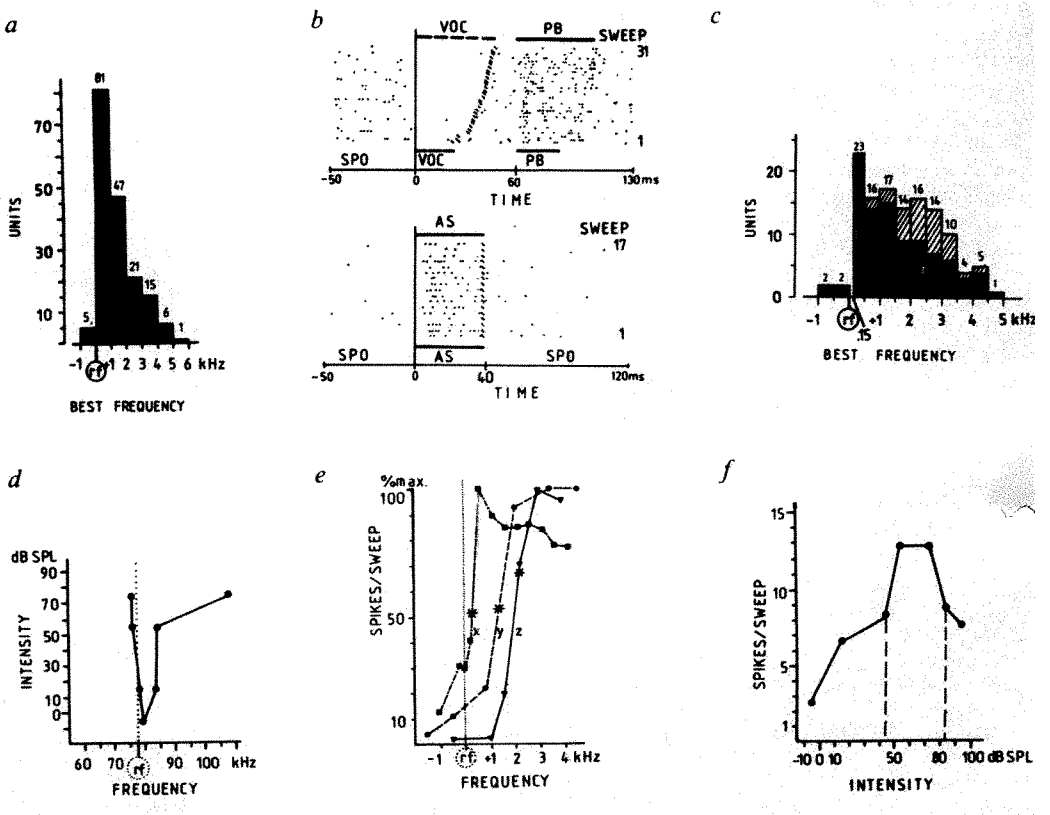

FIG. 1 *a*, AV neurons are tuned to best frequencies between 1 kHz below the resting frequency (RF) and 6 kHz above ($n=179$). *b–f*, VOC-inhibitory neurons. *b*, Raster displays of spike occurrence (dots) as function of time (abscissa) over 31 'sweeps' (upper display) and 17 sweeps (lower display) (ordinate). *b* (upper display), Background activity (SPO) is suppressed during VOC, whereas acoustic VOC-playback (PB) elicits excitation. VOC periods are arranged according to increasing VOC duration from bottom to top. Onsets of VOCs at vertical line, ends of VOCs at slashes. SPO is higher (59 spikes per s) around periods of vocalization (upper display) than during periods of silence (19 spikes per s) (lower display). *b* (lower-display), VOC-identical, artificially generated auditory stimuli (AS) are also excitatory (compare with upper display) (fundamental frequency at RF/2; second harmonic at RF; intensity, 85 dB SPL (dB relative to 2×10^{-5} Pa (sound pressure level)); duration, 40 ms). *c*, Most neurons had best frequencies from 0.15–5 kHz above RF ($n=94$ dotted columns). Of 29 paralemniscal neurons, 26 failed to show VOC inhibition, but otherwise responded similarly and were tuned between 1 and 4 kHz above RF ($n=29$, hatched columns). No unit was tuned to frequencies between RF and 0.15 kHz above. *d*, Individual tuning curve. Note shallow slope for frequencies above best frequency. Average Q_{10dB}-value (best frequency divided by width of tuning curve 10 dB above minimum threshold) near 30. *e*, Variations of pure-tone frequency of 150 Hz around best frequency (asterisks, three units x, y and z) caused 10% change in discharge rates, which remained high at frequencies 3–4 kHz above best frequencies. *f*, Spike-count functions are non-monotonic.

METHODS. Single unit activity during vocalization and in response to auditory stimuli were tested in midbrain and brainstem of spontaneously vocalizing rufous horseshoe bats under local anaesthesia. For surgical preparation stereotactic methods, stimulus presentation, neuronal recording techniques see refs 22 and 23. Auditory stimuli: playbacks of vocalizations (transient recorder; variable output delay; sample rate, 1 MHz)[5] and artificially generated auditory stimuli. Harmonic composition of vocalization was retained[2]. Intensities were at acoustically self-perceived VOC level[24]. Respiration was measured by anemometer. No neuronal activity was linked to expiration alone. Anatomical connections of paralemniscal zone were determined by injection of wheat germ agglutinated to horseradish peroxidase in three bats (TMB and DAB techniques[15,25,26]). Control injections were in adjacent regions of three additional bats.

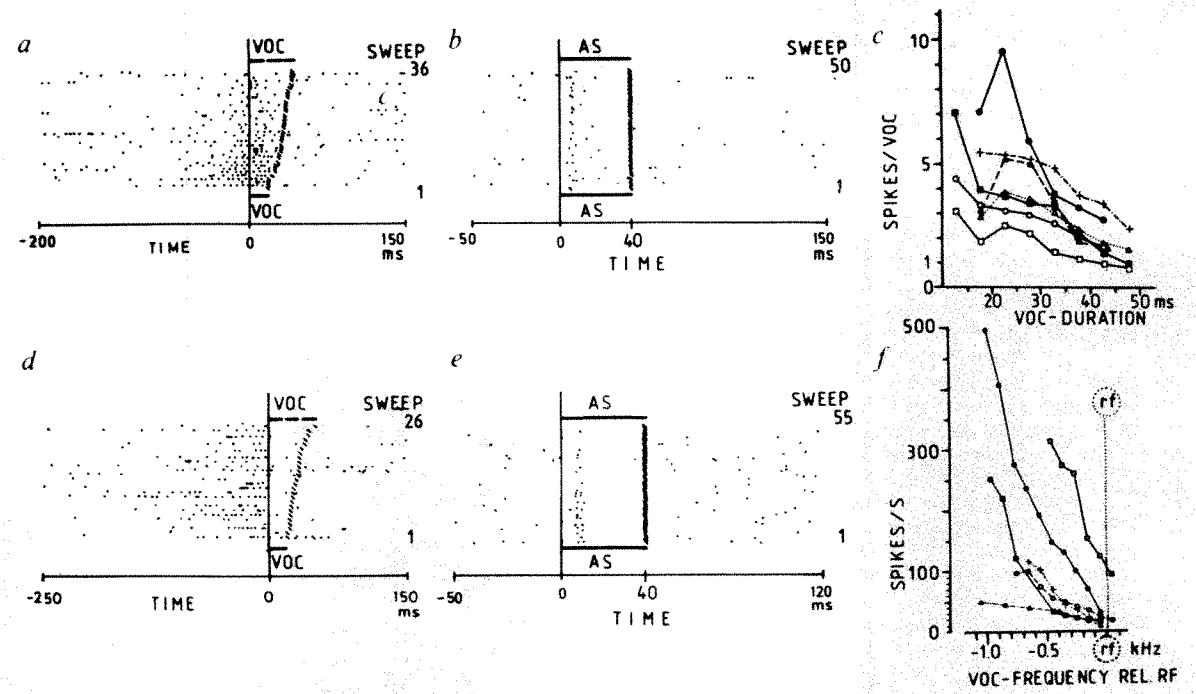

FIG. 2 Pre-vocal excitation was found in 63 of 189 AV neurons. Parts *a,b,d* and *e* follow the convention of Fig. 1*b*. VOC-duration neurons (*a–c*) raised the firing rate as early as 50 ms before the onset of VOC and remained excited during vocalization. Vocalizations are arranged according to increasing VOC length from bottom to top. Note the negative correlation between length of VOC and discharge activity. *b*, Auditory stimulation alone elicited phasic discharges with an average latency of 5.1 ms (±1.6 ms). *c*, Relationship between the duration of VOC and discharge activity (number of spikes) for seven single units. No correlation with the frequency of vocalization was found. The discharge rate of VOC-frequency neurons (*d–f*) increased up to 150 ms before the onset of VOC and stopped with the beginning of vocalization. *e*, Auditory stimuli elicited phasic responses with latencies of 10.5 ms (±2.1 ms) and habituated after the presentation of ~40 stimuli. *f*, Frequency and discharge rate are negatively correlated. On average, a decrease of 1 kHz was accompanied by an increase of 75 spikes per s. No correlation with VOC length was observed. VOC frequency relative to resting frequency is plotted against discharge rate.

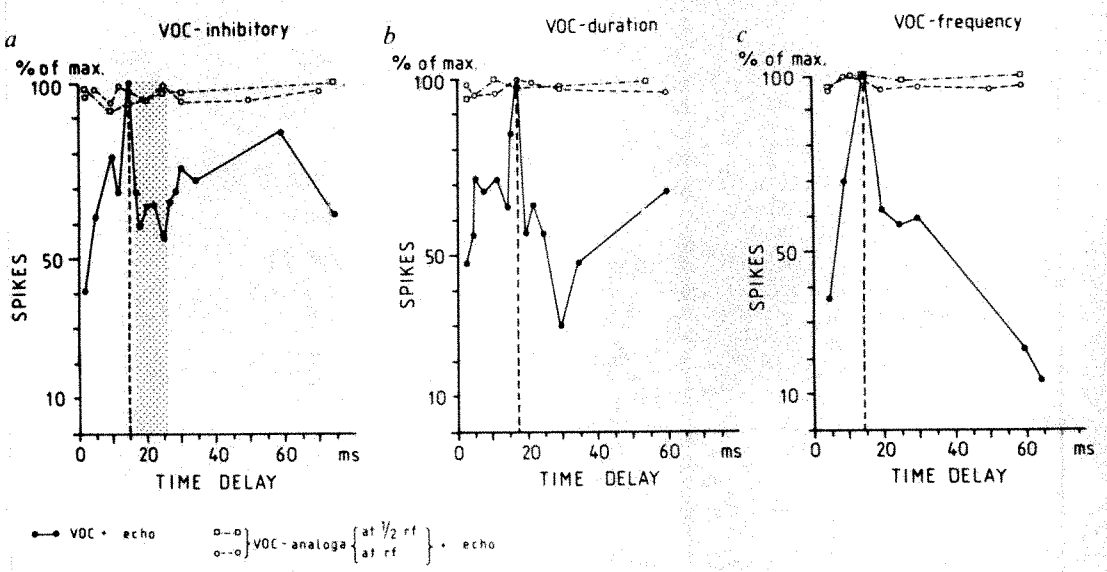

FIG. 3 An auditory stimulus after a vocalization gave a neuronal response to these 'echoes' which was dependent on the intervening time delay. Responses of single unit (relative number of spikes) of each type are normalized with reference to maximal discharge (●). Distinct maxima occurred in the VOC-inhibitory (15 units) (*a*) and VOC-frequency neurons (4 units) (*c*) at delays between 5 and 18 ms. In VOC-duration neurons (*b*), 'best' delays varied between 15 and 30 ms (6 units). In all VOC-inhibitory neurons (*a*), auditory responses were reduced up to 50% between 18 and 25 ms (shaded area). This distinct reduction at intervals greater than the optimal delay for excitation was found consistently only in VOC-inhibitory units (*a*). The delay sensitivity completely disappeared in all neurons when vocalization was replaced by an auditory stimulus that simulated the bat's vocalization. Stimuli simulating vocalization at the fundamental frequency, □; VOC-simulating stimuli at second harmonic, ○.

METHODS. After characterizing basic properties of AV neurons, an auditory stimulus (echo) at the neuron's best frequency, at an intensity of 60–70 dB SPL, and with a duration of 40 ms was triggered by the onset of VOC at a chosen time delay. As a control, vocalization was replaced by an auditory mimic. Harmonic composition of vocalization was retained by using fundamental and second-harmonic frequencies of echolocation call. Intensity of VOC-mimicking signal was 80–90 dB SPL, duration 40 ms. Echo parameters were identical to the VOC-triggered situation.

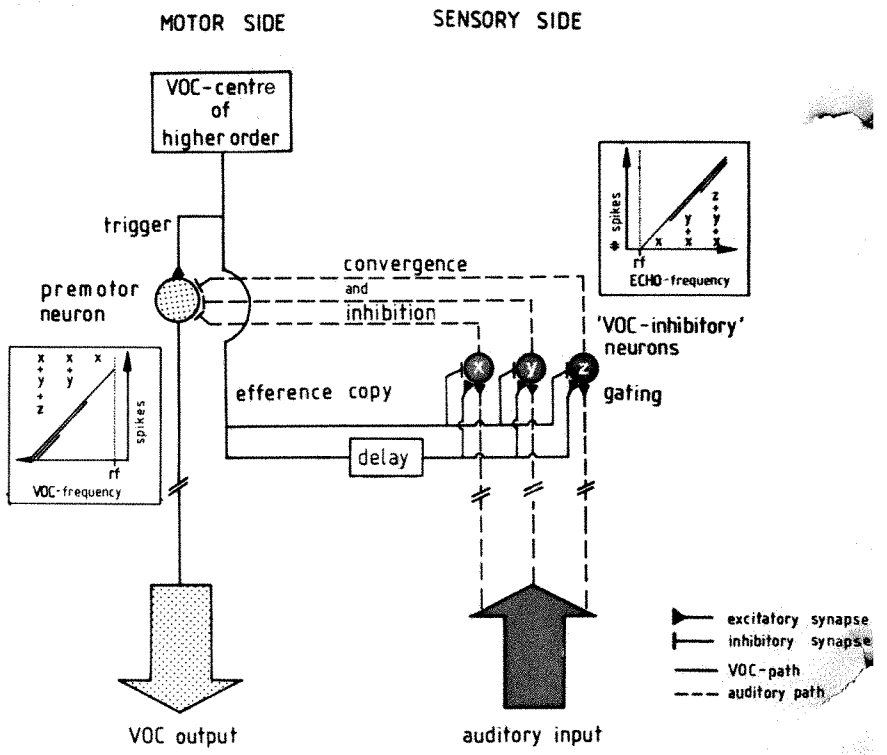

FIG. 4 Model for the regulation of vocalization frequencies (motor output, left) by VOC-inhibitory neurons coding Doppler-shifted echoes (sensory input, right) (see Fig. 1 *b–f*). During vocalization, the background activity of VOC-inhibitory neurons is suppressed by means of an inhibitory efference copy of the bat's echolocation call (Fig. 1*b*, upper display). Echo information arrives via an excitatory auditory input (Fig. 1*b*, lower display). A delayed excitatory neuronal copy of the vocalization could gate the response to returning echoes of distinct time delays (Fig. 3; ref. 6). Small increments in echo frequency above the resting frequency elicit rises in single-unit activity, until a maximum rate is attained (Fig. 1*e*). Additionally, neurons with higher best frequencies will then be recruited successively (Fig. 1*e*, neurons x, y, and z). Hence, the total activity of this neuronal population will increase with the amount of frequency-shift above the resting frequency (inset on right). If the outputs of VOC-inhibitory neurons converged via an inhibitory synapse (note glutamic acid decarboxylase-positive labelling of paralemniscal neurons) onto pre-motor neurons or motoneurons that show high 'resting' activity at the resting frequency, higher spike rates in this paralemniscal neuronal population x, y and z would lower the spike rates in pre-motor neurons or motoneurons (inset on left), and would thus lower VOC frequencies[9,21]. The information provided by neurons x, y and z would be stored to affect the subsequent echolocation call triggered some ten milliseconds later[3,27].

50 ms (Fig. 2*a–c*). An increase in discharge rates correlated with a decrease in the duration of VOC ('VOC-duration' neurons). Discharges in the remaining 25 prevocal-excitatory units started by as much as 150 ms before the onset of VOC (Fig. 2*d–f*). The discharge rates of these 25 units increased with decreasing VOC frequency ('VOC-frequency' neurons). The encoded call frequencies and lengths match those occurring in Doppler-shift compensation[3,6].

In 41 AV neurons, I simulated echo-location situations by triggering an auditory stimulus ('echo') from the onset of VOC and varying the time delay relative to vocalization. Of these, 25 were sensitive to echo delay (Fig. 3). This sensitivity completely disappeared when vocalization was replaced by an identical auditory stimulus. Sensitivity to a delayed echo, therefore, is triggered by the vocalization itself and not by auditory self-stimulation. This demonstrates interactions between auditory processing and vocalization at the single-neuron level. The time delays for the maximum response in VOC-inhibitory and VOC-frequency neurons, ranging from 5–18 ms, correspond to the echo delays necessary for Doppler-shift compensation in horseshoe bats[6]. Additionally, in all VOC-inhibitory neurons, delays ranging between 18 ms and 25 ms resulted in reduced responses to the echo. In rufous horseshoe bats, echoes that return later than 20 ms, fail to induce Doppler-shift compensation (I. Neumann, personal communication; ref. 6).

There are several anatomical connections between the paralemniscal zone and the nucleus ambiguus, the motor nucleus of laryngeal control[10,15,20]. Most prominent are those via the reticular formation medial to the facial nucleus, and via the extreme rostral part of the inferior colliculus. The physiological properties of AV neurons indicate two mechanisms of VOC frequency control in response to Doppler-shifted echoes.

First, VOC-frequency could be encoded by the firing rate of paralemniscal VOC-frequency neurons, which show increases in spike rates with decreasing VOC-frequencies (Fig. 2*f*). In nucleus ambiguus motoneurons and in the superior laryngeal nerve of the horseshoe bat, however, decreases in VOC-frequencies are caused by decreasing spike rates[9,21]. The transfer of frequency information from VOC-frequency units to motor commands in the nucleus ambiguus would therefore require inversion by means of inhibition. This hypothesis is supported by the fact that most paralemniscal neurons are positive for glutamic acid decarboxylase, indicating a role for the inhibitory transmitter GABA (γ-aminobutyric acid) in the paralemniscal zone (M. Vater, personal communication). Second, as shown in Fig. 4, VOC-inhibitory neurons could provide sensory information necessary for regulating vocalization frequencies through auditory feedback. Further investigations are required to determine whether the transformation of this sensory information to final motor commands takes place at the level of the paralemniscal zone.

Optical imaging of calcium accumulation in hippocampal pyramidal cells during synaptic activation

Wade G. Regehr, John A. Connor* & David W. Tank†

Molecular Biophysics Research Department, AT&T Bell Laboratories, Murray Hill, New Jersey 07974, USA

THE dynamic response of nerve cells to synaptic activation and the spatial distribution of biochemical processes regulated by ion concentration are critically dependent on the cell-surface distribution of ion channels. In the hippocampus, intracellular calcium-ion concentration is thought to influence the biochemical events associated with kindling[1,2], excitotoxicity[3,4], and long-term potentiation[5–12]. Computer models of hippocampal pyramidal cells[13] also indicate that calcium-channel location influences dynamic characteristics such as bursting[14,15]. Here, we have used *in situ* microfluorometric imaging[16] in brain slices to directly measure the spatial distribution of calcium accumulation in guinea-pig CA1 pyramidal cells during trains of orthodromic synaptic stimulation. Calcium accumulation is substantial throughout the entire proximal section of the apical and basal dendrites. Most of this accumulation results from influx through non-NMDA (*N*-methyl-D-aspartate) voltage-gated calcium channels, and in the apical dendrite it drops steeply as the dendrite enters stratum moleculare, the termination zone of perforant path afferents. These results demonstrate a marked segregation of calcium-channel activity and directly show a spatial distribution of calcium accumulation during orthodromic synaptic activation.

* Present address: Department of Neuroscience, Roche Institute of Molecular Biology, Nutley, New Jersey 07110, USA.

† To whom correspondence should be addressed.

Individual pyramidal cells in the CA1 region of a guinea-pig hippocampal slice were filled with the pentapotassium salt of fura-2 by iontophoretic microinjection. Maps of intracellular free-calcium concentrations ($[Ca^{2+}]_i$) were determined from the ratio of low-magnification fluorescence images (Fig. 1*a*, *e*) excited at 340 nm and 380 nm (ref. 17). Exposure times were 0.4–2 s and the calculated concentrations represent time-averaged values of $[Ca^{2+}]_i$.

Orthodromic synaptic activation of pyramidal cells through stimulation of the stratum radiatum with bipolar electrodes produced widespread calcium accumulation and large spatial gradients in the dendrites. The stimulus conditions used were based on those widely employed in long-term potentiation (LTP) experiments and reliably produced LTP in control slices (see Fig. 1 legend). As shown in the colour-coded $[Ca^{2+}]_i$ maps in Fig. 1*b–d*, stimulation at 50 Hz for 2 s produced a large increase in $[Ca^{2+}]_i$ in the proximal-apical and basal dendrites (Fig. 1*c*),

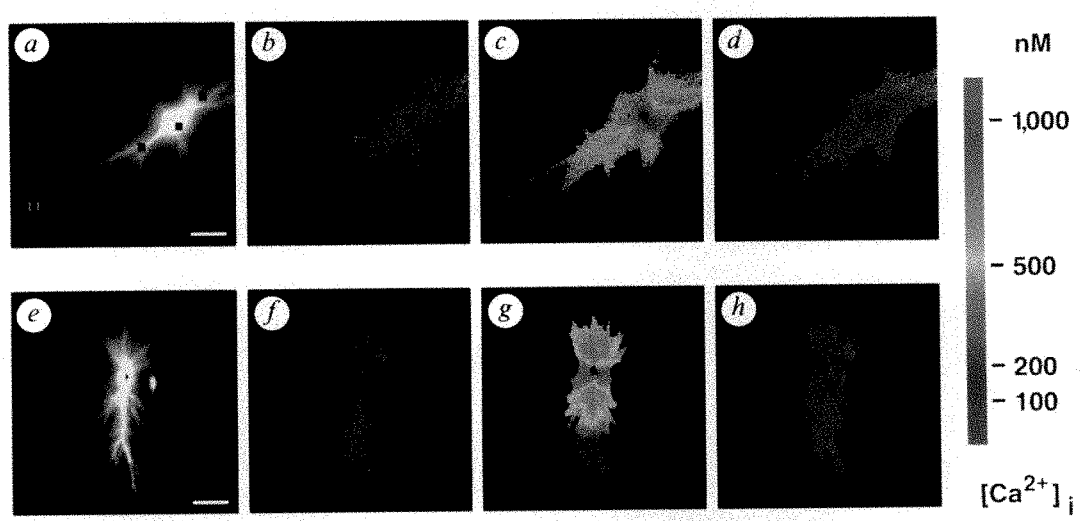

FIG. 1 *a*, Fluorescence image of a CA1 pyramidal cell filled with fura-2 by microinjection (380 nm excitation; 300 × 300 pixels). The fluorescence intensity was used to create a mask that defined where ratios and the associated $[Ca^{2+}]_i$ were subsequently computed. *b–d*, Maps of $[Ca^{2+}]_i$ before (*b*), during (*c*), and 17 s after (*d*) orthodromic synaptic activation of the cell in *a* produced by stimulation of the stratum radiatum (50 Hz, 2 s). *e*, Fluorescence image (380 nm excitation; 150 × 150 pixels) of a different CA1 pyramidal cell. *f–h*, Maps of $[Ca^{2+}]_i$ before (*f*), during (*g*), and 50 s after (*h*) orthodromic synaptic activation (20 Hz, 10 s) of the cell shown in *e*. Dark pixels within the soma represent locations where fluorescence saturated the CCD (charge-coupled device) camera; ratios are therefore not displayed. Scale bars, 100 μm.

METHODS. Experiments were performed on 300-μm thick transverse slices of hippocampus from 90–400-g guinea pigs. Slice preparation and maintenance *in vitro* followed standard procedures[25,26]. For imaging, slices were placed on a glass coverslip that was the bottom of a submerged slice chamber, and continuously perfused with saline (30–32 °C) of the following composition (mM): NaCl, 124; KCl, 5; $CaCl_2$, 2; $MgCl_2$, 1.6; $NaHCO_3$, 26; glucose, 10; equilibrated with 95% O_2/5% CO_2. CA1 pyramidal neurons were injected with microelectrodes pulled on a Brown-Flaming puller (Sutter) from 1.5-mm tubing (No. 6030 AM Systems) containing a 12-mM solution of the K^+ salt of fura-2 (ref. 17) (Molecular Probes) in 100 mM KCl. After bevelling (Model BV-10, Sutter), electrode resistance was 150–200 MΩ. Cells having a stable resting potential of ≥ -50 mV and responding to brief depolarizations with a burst of action potentials were injected with fura-2 by continuous iontophoretic current (−1 nA; 10 min). Only neurons located within 100 μm of the surface of the slice were used in these experiments; at greater depths image clarity was reduced. Orthodromic activation of CA1 neurons was produced by stimulation of the stratum radiatum (300–600 μm from the cell, midway between stratum moleculare and stratum pyramidale) with bipolar tungsten electrodes (25 μm diameter, polyimide coated; California Fine Wire) with trains of 400–1,000 μA current pulses (100 μs pulse duration). In control slices using 0.1 Hz test pulses, the evoked field potentials (measured using extracellular electrodes, No. 6030 AM Systems, 2 M NaCl, 4–6 MΩ) were 0.3–0.8 mV in stratum radiatum and the population spike in stratum pyramidal 0.5–3.5 mV. Tetanic stimuli (50 Hz, 2 s) and (20 Hz, 10 s) reliably induced potentiation in 10 control slices, as indicated by an increase in the slope of the field potential in stratum radiatum (average 25% increase, range 18%–33%, $n = 4$) and an increase in the amplitude of the population spike in stratum pyramidale (average 216%; range 139%–343%; $n = 6$). Cells were viewed from the top surface of the slice using an upright microscope (Zeiss UEM) and a Nikon ×10 UVF objective covered with Saran Wrap (Dow) for water-immersion use. Alternatively, cells on the bottom of the slice were viewed through the glass coverslip using an inverted microscope (Zeiss IM35) with the same objective but without the Saran Wrap. Images were taken with cooled CCD cameras (model 220, Photometrics) with Macintosh II (Apple) controlled image acquisition and display. $[Ca^{2+}]_i$ was determined from images at 340 nm and 380 nm excitation using the ratio method[17,27]. Reported $[Ca^{2+}]_i$ values assumed a viscosity correction corresponding to a 30% reduction in the 340/380 nm fluorescence ratio[28]. Although several factors can contribute to errors in our calculations of absolute concentrations (non-uniformity of background fluorescence, choice of viscosity correction factor), under static conditions computed fluorescence ratios varied by less than 5%. In Figs 2–4, times refer to the midpoint of image pairs relative to the start of stimulation.

which recovered to the pre-stimulus level following stimulation (Fig. 1*d*). Figure 1*f–h* shows a similar sequence of $[Ca^{2+}]_i$ maps for a different pyramidal neuron (20 Hz, 10 s stimulation). This same basic pattern of calcium accumulation with afferent activation was measured in all 26 pyramidal cells tested.

The time course of calcium accumulation and recovery for the experiment shown in Fig. 1*b–d* is plotted in Fig. 2 for the four locations indicated in Fig. 1*a*: basal dendrite, soma, proximal apical dendrite and distal apical dendrite. During the 2 s stimulation period, the largest (more than sevenfold in this cell) and most rapid accumulation occurred in the proximal dendrites; accumulation in the soma lagged behind the dendritic response and was greatly reduced in amplitude. Only a small increase was observed in the distal apical dendrite. For the 26 cells measured, stimulation at 50 Hz for 2 s, or 20 Hz for 5 or 10 s, produced peak calcium levels in the basal and apical dendrites, that ranged from 600 to 2,000 nM; calcium accumulation in these regions decreased by 50% in 1–5 s after stimulation. The return to pre-stimulus levels for the soma was somewhat slower, requiring 10–20 s to decrease by 50%. All regions eventually returned to the pre-stimulus levels, requiring 30–90 s for the dendrites and ~5 min for the soma.

To demonstrate that the calcium accumulations were produced by synaptic activation and to rule our direct depolarization of the pyramidal cell by the stimulating electrode, postsynaptic currents were blocked with the non-NMDA glutamate receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (ref. 18) (CNXQ; 40–100 μM; Tocris Neuramin). Figure 2*b* shows plots of calcium accumulations with time in representative sections of apical and basal dendrites and soma in normal saline (solid curves) and after bath application of CNQX (40 μM; dashed curves). The tetanus-induced calcium accumulation was completely blocked by CNQX ($n = 5$). In separate experiments, afferent-fibre activation was blocked by bath application of the voltage-dependent sodium-channel blocker tetrodotoxin (TTX; 1 μM; Sigma). Tetanus-induced calcium accumulation was also completely blocked under these conditions ($n = 3$; data not shown). The calcium accumulations observed in normal saline were produced, therefore, by synaptic activation of the pyramidal cell.

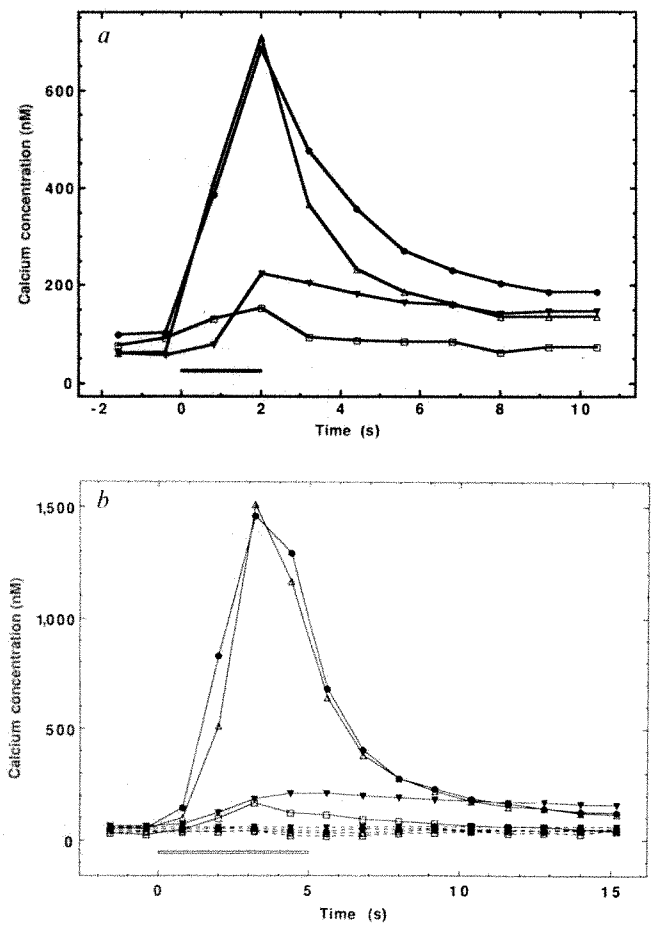

FIG. 2 *a*, Graph of calcium accumulations against time at the four spatial positions indicated in Fig. 1*a*. Circle, basal dendrite; triangle, proximal apical dendrite; inverted triangle, soma; square, distal apical dendrite. During the period indicated, the pyramidal cell was stimulated (50 Hz, 2 s) with current pulses applied to a bipolar electrode located in the stratum radiatum. *b*, Effect of CNQX on calcium accumulations produced by stimulation (20 Hz, 5 s) for a different pyramidal cell. Plot key as in *a*. Solid lines show accumulations in normal saline against time. Dashed lines show complete block of the response following bath application of 40 μM CNQX.

Quantitative comparison of calcium distribution under different conditions was facilitated by plotting $[Ca^{2+}]_i$ against distance along the dendrite. In Fig. 3*b* the average levels of $[Ca^{2+}]_i$ in small regions (Fig. 3*a*) along the lengths of apical and basal dendrites are plotted (solid lines) against distance from the cell-soma centre for the primary apical dendrite and a representative basal dendrite. Individual curves for four time points during the rising phase of calcium accumulation are superimposed. In the 26 cells analysed in this manner, the peak accumulation level along the apical dendrite occurred at an average distance of 105 ± 30 μm from the soma, with a sharp decline in accumulation between 150 and 250 μm. The gradient of free calcium along this declining section was typically 5–20 nM per μm at the peak of the accumulation. The half-maximal distance from the cell soma was 180 ± 50 μm. Very little accumulation was observed in distal dendritic regions corresponding to stratum moleculare (a mean increase of 40 ± 30 nM at 400 μm from the soma, $n = 16$), which in this preparation begins 250–380 μm from the cell-body layer.

In all cells tested ($n = 26$) apical dendritic activation by stimulation of the stratum radiatum also produced increases in the basal dendrites. Similarly in all of five cells tested, basal dendritic activation by stimulation of stratum oriens produced both basal and apical dendritic accumulations. These results indicate that most of the measured accumulation was produced by action-potential invasion or spreading depolarization which activated voltage-dependent calcium conductances. To distinguish between transmitter-gated calcium fluxes produced by NMDA-receptor activation and those due to activation of strictly voltage-dependent calcium channels[19], concentrations produced by action-potential trains driven by current pulses from an intracellular microelectrode were measured. The effect of NMDA-receptor blockers on the calcium accumulation was also determined.

During intracellular microelectrode impalements (Fig. 3*c*), cell-soma images were corrupted by the dye-containing microelectrode, but measurements could still be made reliably in dendritic areas and other unobstructed parts of the soma. Calcium accumulation for representative apical and basal dendrites is plotted in Fig. 3*d* for both a quiescent period and during action-potential stimulation by depolarizing current pulses (20 Hz). In all of seven neurons stimulated in this manner, large increases in the proximal apical and basal dendrites were observed with a strong decay of accumulation in the apical dendrite at soma distances of 150–250 μm. Peak calcium accumulation in the principal apical dendrite occurred between 65 and 210 μm from the soma. These intracellular microelectrode experiments provide further evidence that the accumulations observed with orthodromic synaptic stimulation were produced primarily by non-synaptic voltage-dependent calcium fluxes.

Under the present experimental conditions, bath perfusion with the NMDA-receptor antagonist DL-2-amino-5-phosphonovaleric acid (AP5; 100–200 μM; Sigma) produced no statistically significant change in the levels of calcium accumula-

tion produced by orthodromic synaptic activation (Fig. 4). Cells were first bathed in AP5 and images taken during tetanic stimulation (20 Hz; 10 s); after extensive washout (15–30 min) a second set of images at identical time points was taken during identical stimulation. In eight experiments comparing the stimulation of stratum radiatum in AP5-containing medium with that in normal medium, the average reduction of apical dendritic calcium accumulation was $3 \pm 10\%$, compared with an average reduction of $2 \pm 10\%$ for basal dendrites (Fig. 4). Similar results were obtained for side branches of the primary apical dendrite. Three cells showed decreases in the peak calcium levels reached in the proximal apical dendrite, but not basal dendrites, in AP5-bathed cells compared with the control condition (Fig. 3*b*; dashed lines). Under our experimental conditions, a contribution to calcium accumulation caused by influx through NMDA-receptor channels during tetanic afferent stimulation was difficult to resolve because of variability between trials and the presence of much larger AP5-insensitive accumulations.

These *in situ* determinations of calcium changes in hippocampal pyramidal cell dendrites responding to presynaptic stimulation are a significant advance. They demonstrate that intracellular depolarization and tetanic orthodromic stimulation of the Schaffer collateral afferents to CA1 hippocampal pyramidal cells cause a large transient accumulation of $[Ca^{2+}]_i$ throughout the proximal apical and basal dendrites. At these locations, the second messenger functions of calcium might be employed to activate calcium-dependent biochemical processes. In our experiments, synaptic activation did not produce the sustained dendritic calcium gradients that have previously been measured in accurately dissociated hippocampal neurons in response to NMDA (ref. 20). The accumulation during stimulation seems to be produced primarily by the activation of voltage-dependent calcium channels localized on the proximal apical and basal dendrites, although a contribution to calcium accumulation by release from internal stores cannot be ruled out. The accumulation in proximal apical dendrites is consistent with electrophysiological evidence for voltage-dependent calcium conductances in CA1 hippocampal pyramidal cell dendrites[21–23]. We have also shown calcium accumulation in the basal dendrites and a strong decay of accumulation along the apical dendrite. In distal dendritic regions beyond 250 μm from the soma, little accumulation is observed. In the guinea pig hippocampus, the stratum

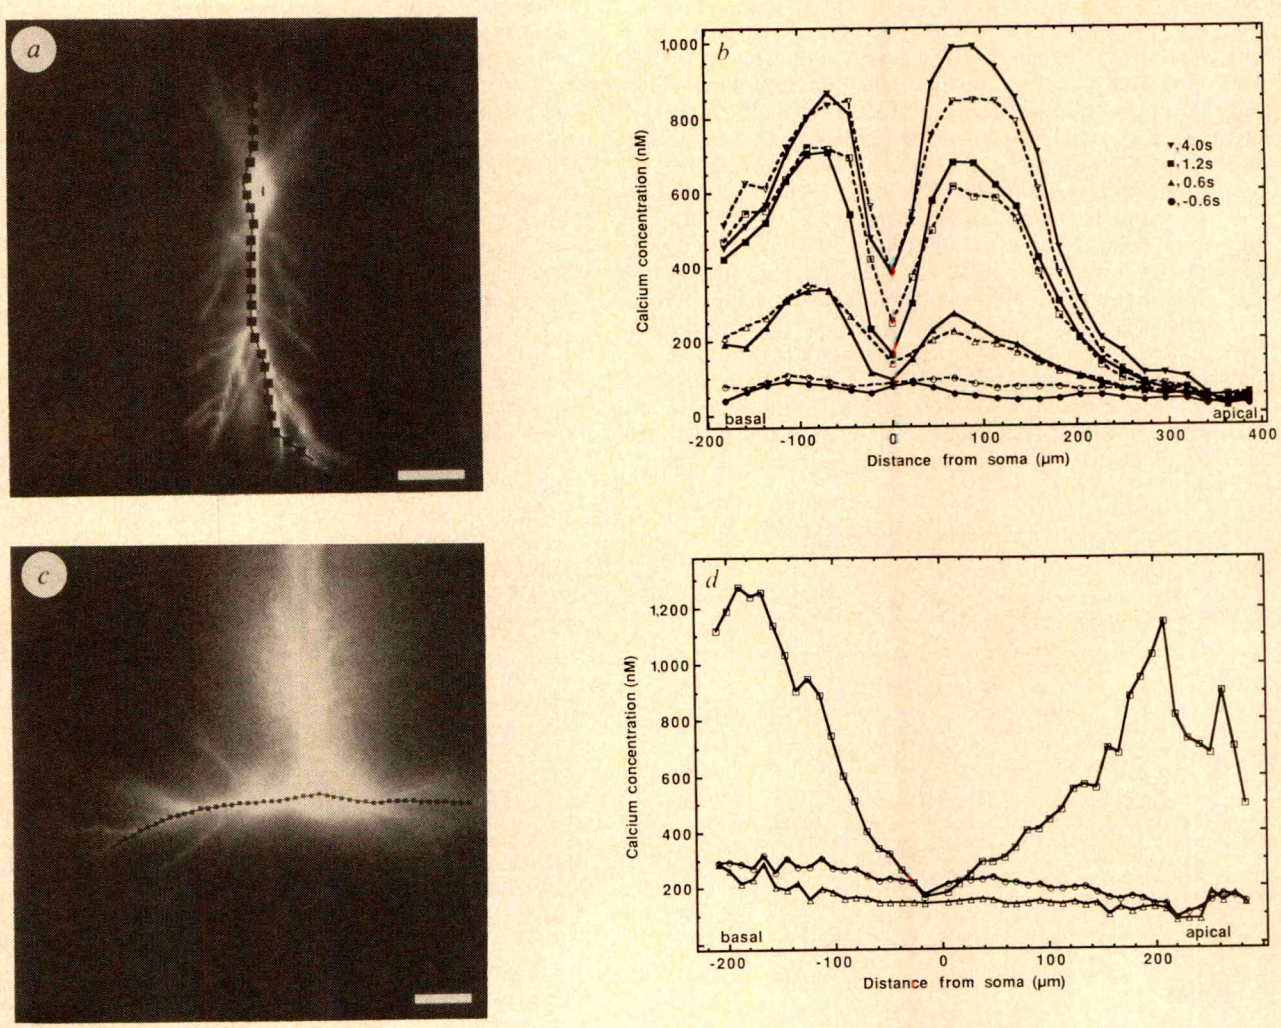

FIG. 3 *a*, Fluorescence image (380 nm excitation) of the cell shown in Fig. 2*e* with superimposed string of analysis boxes traversing sections of apical and basal dendrite. Calcium accumulations were calculated within each box for image pairs taken during orthodromic activation of Schaffer collateral afferents (20 Hz, 10 s). *b*, Graph of calcium accumulation in the analysis boxes shown in *a* against distance from the cell soma centre in the presence of AP5 (dashed lines) and after washout (solid lines). Curves are shown for several time points during the increasing accumulation phase of the response. *c*, Fluorescence image (380 nm excitation) with superimposed analysis boxes of CA1 pyramidal cell penetrated by a fura-2 filled intracellular microelectrode used to fill the cell with indicator and to inject depolarizing current. *d*, Graph of calcium levels measured in the boxes shown in *c* against distance from the cell soma for image pairs taken at rest and during a train of depolarizing current pulses (20 Hz). Triangle, before; circle, after; square, during stimulation. Scale bars, 100 μm.

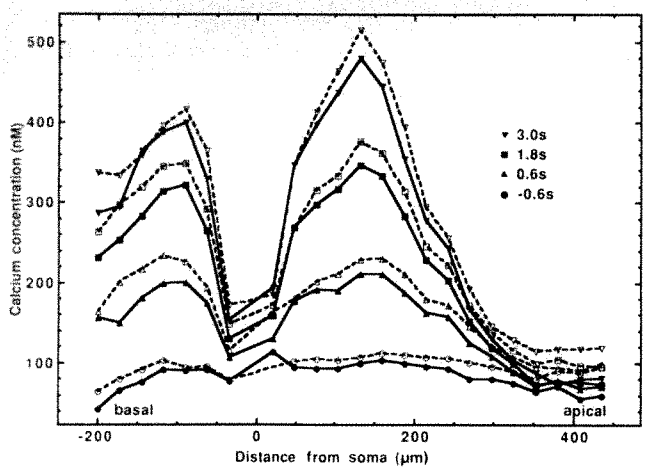

FIG. 4 Graph of calcium accumulation in dendritic regions of a pyramidal cell (image not shown) against distance from the cell soma centre in the presence of AP5 (dashed lines) and after washout (solid lines). Curves are shown for several time points during the increasing accumulation phase of the response.

moleculare region begins 250–380 μm from the cell soma layer and contains both perforant path inputs from entorhinal cortex and thalamic afferents that are distinct from the Schaffer collateral system (CA3 efferents) that synapse in the stratum radiatum and stratum oriens. The sharp calcium gradient we observed probably reflects a lower density of active voltage-gated calcium channels in the distal dendrite, as the electrotonic properties of CA1 cells are not consistent with a sharp voltage gradient[24]. We surmise that this calcium channel localization represents the physical substrate for a different computational or learning role of proximal and distal apical dendritic segments. *Note added in proof*: In recent experiments similar to those shown in Fig. 3*b*, but employing higher stimulus frequencies and increased temporal resolution, we have reliably resolved a transient component of calcium accumulation that is blocked by AP5 and localized to dendritic regions near activated afferent fibres. □

Release of endogenous excitatory amino acids from turtle photoreceptors

RESPONSES to light are transmitted from photoreceptors to second-order retinal neurons by chemical synapses that may use an excitatory amino acid (EAA) as the neurotransmitter. This hypothesis is based primarily on the pharmacological actions of EAA agonists and antagonists on the membrane potentials and light responses of second-order neurons[1,2]. But the release of endogenous EAAs, which is a critical criterion for the identification of EAAs as transmitters[3], has not been demonstrated. Here we report the use of outside-out membrane patches excised from rat hippocampal neurons to detect the release of EAAs from synaptic terminals of isolated turtle photoreceptors. Electrical stimulation of or application of lanthanum chloride to photoreceptors induced an increase in the frequency of opening of 50-pS channels in the patches. These channels were identified as the class of glutamate-activated channels that are also gated by aspartate and NMDA (*N*-methyl-D-aspartate). In several photoreceptor–patch pairs spontaneous channel activity was observed near the synaptic terminals. These results provide strong evidence to support the hypothesis that both rods and cones of the turtle use an EAA as their neurotransmitter.

Excised membrane patches that contain ion channels gated by nicotinic cholinergic agonists have been used to sense the release of acetylcholine from growth cones of developing neurons[4,5]. We used EAA-sensitive membrane patches to test whether there is a detectable release of a glutamate-receptor agonist from the synaptic terminals of individual rods and cones. Outside-out patches were excised from rat hippocampal neurons that had been grown in primary culture[6] (see Fig. 1 legend). Both EAA-activated and non-EAA-activated channels are found in these patches. Our strategy was to create a sensitive and selective probe for EAAs by pharmacologically blocking all non-EAA-gated channels (see Fig. 1 legend). Under these conditions, we characterized the properties of patches taken from the same or similar batches of hippocampal cells as those that were used to detect release. Every patch responded to exogenous L-glutamate, L-aspartate and NMDA with channel openings identified as NMDA-gated channels. The channels exhibited the typical 45–50-pS conductance (and subconductance states[6–8]), were blocked by the specific antagonist D-2-amino-5-phosphonovalerate[6], had reversal potentials close to 0 mV, were blocked by elevated Mg^{2+} at hyperpolarized potentials[7] and were sensitized by glycine[9]. In test solutions containing 2 μM glycine, an increase in NMDA-gated channel activity was readily discernible at NMDA concentrations of 0.5 μM and glutamate concentrations of 0.1 μM.

Acutely isolated photoreceptors from dissociated turtle retinas[10] (see Fig. 1 legend) and cultured hippocampal cells were placed in the same media-filled recording chamber. An outside-out patch was detached from a hippocampal neuron, positioned within 2 μm of a photoreceptor synaptic terminal, and a stimulating electrode was placed so that it just touched the distal end of the inner segment of the photoreceptor. Figure 1*c* shows the electrodes positioned near an isolated rod photoreceptor. At least one control run of channel activity was always recorded before stimulation. Photoreceptors were stimulated with pulses of positive voltage (0.1–5 V for 50–1,000 ms) applied through the stimulating electrode. Such stimuli were expected

to depolarize the synaptic terminals in the same manner as the trans-retinal currents that have been passed across intact retinas to evoke transmitter release from photoreceptors[11]. Figure 1(*a*, *b*) displays sample records of channel openings (downward deflections) recorded from an outside-out patch positioned near the synaptic terminal of a yellow cone during a control period and immediately after a 500-ms stimulus pulse. Within 200 ms after the onset of stimulation, an increase in channel activity was observed. After an interval of increased channel activity lasting up to 30 s, the probability of channel opening returned to pre-stimulus levels (see Fig. 1*d*).

Channel activity was quantified by integrating the total current that flowed across the patch during each trial period. Figure 1*d* shows that the time-averaged current induced by electrical stimulation (trial 3) was ~10 times higher than the time-averaged current for the previous two control runs. In 5 of 13 photoreceptor-patch pairs, the increase in the time-averaged current due to electrical stimulation was more than nine times greater than the control recordings (mean increase, 16.8-fold; range 9.6-31.1-fold; two yellow cones, two red cones and one rod). In two of these pairs, subsequent electrical stimulation after a delay of 60-120 s elicited a second, but smaller, increase in channel activity (5.4- and 9.9-fold increase in time-averaged current). These results suggest that most of the releasable neurotransmitter was secreted as a result of the initial stimulus. In the remaining pairs there was no discernible change in channel activity upon stimulation. Several possibilities could account for these failures: some photoreceptors could have been metabolically compromised during the dissociation and unable to release transmitter; the patches may have contained few channels and therefore had low sensitivity; the synaptic terminals may have been inadequately depolarized because of the low sealing resistance of the stimulating electrode; or the patch could have been too far from a release site for detection. Meriney *et al.*[12] have shown that acetylcholine-sensitive patches are unable to detect acetylcholine release when positioned more than 2-3 μm from a release site.

Spontaneous channel openings, presumably reflecting the release of EAAs from the aggregate retinal neurons, were usually observed regardless of the position of the membrane patch in the recording chamber. The amount of spontaneous channel activity that could be recorded near the photoreceptor terminal, however, was at least four times that recorded at positions 50 μm away (Fig. 1*d*). These findings held for five out of eight photoreceptor-patch pairs (mean increase, 12.54-fold; range 4.3-40.0-fold; one red cone, one blue cone, two yellow cones, two rods). Although the normally short lifetime of the membrane patches made it difficult to quantify significant differences between low rates of channel activity, we found no difference in the rate of channel activity measured just adjacent to the inner segment compared with that measured 50 μm away.

Potassium and lanthanum were applied to photoreceptors to evoke transmitter release. High K^+ (50 mM) applied directly to outside-out patches, however, usually resulted in flickering inward-going channel events, which probably represented K^+ conductances. These events made quantification of NMDA-channel activity impossible. Lanthanum chloride has been used as a secretagogue at the neuromuscular junction[13] and in the retina[11]. Lanthanum chloride was applied from pressure pipettes to the inner segments of isolated photoreceptors. In three of seven photoreceptors (two yellow cones, one rod) the application of La^{3+} resulted in a 3.3-, 12.3- and a 3.6-fold increase in

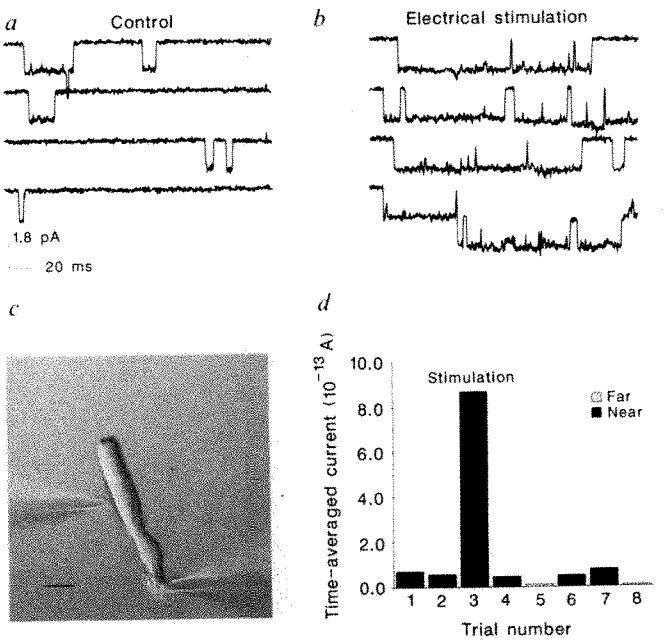

FIG. 1 Stimulation of isolated photoreceptors induces NMDA-channel activity in outside-out patches positioned adjacent to synaptic terminals. *a*, Selected channel openings recorded with the patch positioned within 2 μm of the synaptic terminal of a yellow cone immediately before photoreceptor stimulation. *b*, Records obtained just after extracellular electrical stimulation of the cone. Patch holding potential, −40 mV. Channel openings are downward (inward current). *c*, Isolated turtle rod with patch pipette positioned near the synaptic terminal and stimulating pipette positioned near the inner segment. Scale bar, 10 μm. *d*, Effects of stimulation of the same cone as in *a* and *b*, and position of the patch pipette on channel activity. In each trial, the current was integrated and normalized by dividing by each trial duration, which ranged from 3.28 to 65.12 s (owing to the sampling routine that stored only those 1,024-point sample epochs that contained at least one opening). In trials 1-4 and 6-7, the NMDA-channel membrane patch was positioned near the base of the synaptic terminal of the yellow cone. In trial 3 (corresponding to the records in *b*), current was passed from the stimulating electrode to depolarize the membrane of the cone terminal. In trials 5 and 8 the patch pipette was located ~50 μm away from the terminal but still at the same height (~1-3 μm) from the bottom of the dish to measure background channel activity gated by the bath perfusate (no photoreceptor stimulation).

METHODS. Neurons were obtained from the CA1 region of the hippocampus from 1-3-day-old Long-Evans rats. Dissociation and cell culture methods are described previously[6]. Photoreceptors were dissociated from isolated retinas dissected from *Pseudemys scripta* turtle eyes. Strips (1 mm wide) were incubated in a low Ca^{2+} (no added Ca^{2+}, 10 mM EDTA), cysteine-enriched (1-2 mM) papain solution (7 U ml^{-1}, Worthington) for 30 min, rinsed in Ringer's solution and then triturated in a BSA-coated pipette. Aliquots of supernatant that contained isolated cells were dropped onto glass coverslips covered with collagen/conconavalin A (ref. 10) and allowed to attach for at least 10 min before recording. The external recording solution contained (in mM): NaCl, 165; KCl, 3; CaCl, 2-4; picrotoxin, 0.05; strychnine, 0.001; tetrodotoxin, 0.0005; glycine, 0.002; HEPES buffer, 5 (pH adjusted to 7.4 with NaOH). The internal solution in the patch pipette contained (mM): Cs gluconate, 140; CsCl or NaCl, 10; EGTA, 10; HEPES buffer, 5 (pH adjusted to 7.4 with CsOH). These ionic substituents, buffers and antagonists were chosen to suppress voltage- and ligand-gated channel events commonly found in outside-out patches excised from hippocampal neurons to make selective EAA probes. The internal solution for whole-cell recordings from photoreceptors also contained 1-2 mM CsF. The capacity of the recording chamber was ~0.4 ml. The superfusion rate was ~1.5 ml min^{-1}. Extracellular stimulating electrodes were lightly fire-polished patch pipettes filled with external solution. Experiments were performed at room temperature (21-25 °C) on the stage of a Zeiss IM35 inverted microscope using ×40 water-immersion or ×63 oil-immersion objectives and DIC optics. Lanthanum chloride at an electrode concentration of 5 mM was applied by pressure from unpolished patch pipettes positioned within 10 μm of the photoreceptor inner segment. NMDA, L-glutamate, L-aspartate and acetylcholine were applied to outside-out patches from perfusion tubes with inner diameters of ~200 μm. Solution changes were effected by either moving the perfusion tubes or the patch pipettes, and were completed within 10 ms as determined by the current relaxation that was induced by switching into iso-osmolar KCl-based saline from the normal NaCl-based external solution.

channel activity recorded near the synaptic terminal. Figure 2*a* illustrates the channel activity evoked by ejection of La^{3+} on a yellow cone. Figure 2*b* shows the time-averaged current for three control trials followed by three applications of La^{3+} to this same cone. It is clear from this figure that the second and third applications did not induce the same large increase in channel activity and, in fact, may have slightly decreased channel activity.

To test the possibility that La^{3+} might have been directly activating channels in the patch, we compared channel activity in 5 μM NMDA and 1 μM glycine (upper two traces, Fig. 3*a*) with that recorded in the presence of agonist in addition to 5 mM La^{3+} (middle traces, Fig. 3*a*). We found that La^{3+} did not induce channel activity in the patches but instead reversibly blocked NMDA-activated channels in a voltage-independent manner similar to the effect of zinc[14]. Thus, the increase in channel activation observed with La^{3+} was due to the action of La^{3+} on the photoreceptors. The lack of an increase in channel activity with subsequent applications of La^{3+} may have been due to the delayed block of the NMDA-gated channels by La^{3+} as it diffused to the patch pipette from the region of application or to the depletion of synaptic transmitter in the terminals, or both. In support of the depletion possibility, preliminary electron microscopy of photoreceptor synaptic terminals revealed an almost complete depletion of synaptic vesicles in La^{3+}-treated photoreceptors.

Depolarizing the photoreceptor membrane potential in the whole-cell recording mode proved to be ineffective in evoking transmitter release. With NMDA-sensitive patches near the synaptic terminals, the membrane potential of the isolated rod or cone was stepped from a holding potential of −60 mV, at which level transmitter release is fully suppressed[15,16], to 0 mV, at which level release should be maximal. No change in channel activity in the outside-out patch was observed in all of nine photoreceptor–patch pairs. To test whether dialysis of the interior of the cell during the whole-cell recordings could have disrupted the release process, the pipette potential was held at 0 mV during the transition from the on-cell to the whole-cell configuration. This effectively stepped the photoreceptor membrane potential from rest to 0 mV on breaking into the cell. For two of the three cases tested in this manner, increases in channel activity in the outside-out patch were observed within 200 ms of forming the whole-cell recording from the photoreceptor (Fig. 3*b*). These results indicate that, at least transiently, transmitter release mechanisms were intact in photoreceptors and that the whole-cell recordings may have disrupted these mechanisms.

We have measured evoked and spontaneous channel activity in NMDA-sensitive outside-out patches near the basal surface of the synaptic terminals of photoreceptors. These channels were identified as EAA-gated NMDA channels. No channel activity was induced by GABA (γ-aminobutyric acid) or acetylcholine, two putative photoreceptor neurotransmitters[17–19]. GABA-gated channels were blocked with picrotoxin and would have produced outward-going currents at −40 mV with the chloride concentrations used in our experiments. Neither the patches nor the hippocampal neurons, recorded in whole-cell mode

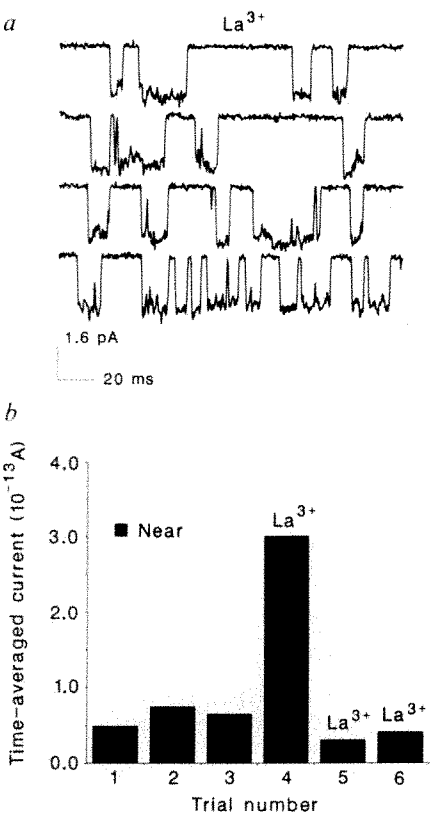

FIG. 2 Channel activity induced by La^{3+} perfusion of the photoreceptor. *a*, Sample records of NMDA channel activity immediately after pressure injection of La^{3+} onto the inner segment of an isolated rod. *b*, Time-averaged current measured before and during three separate pressure ejections of a 1-s pulse of La^{3+} on to the same rod as shown in *a*. The membrane patch was located near the synaptic terminal throughout the course of this experiment. Holding potential, −40 mV.

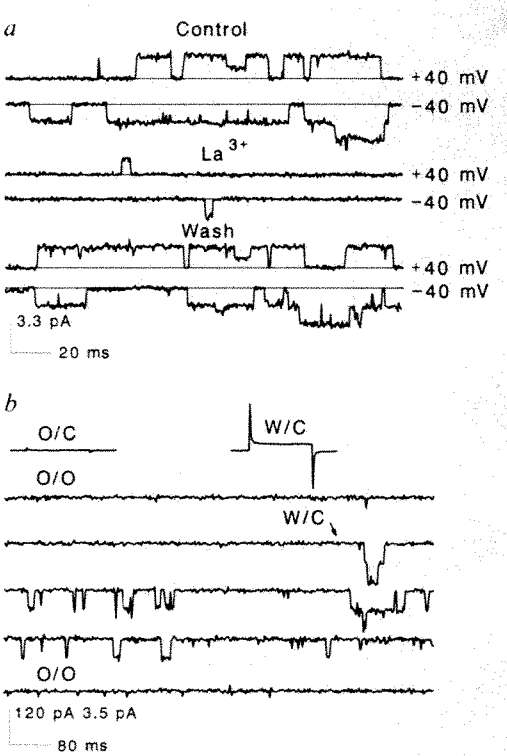

FIG. 3 *a*, Effect of La^{3+} on NMDA-gated single-channel currents. Representative traces of single-channel activity in the presence of 5 μM NMDA and 2 μM glycine (upper traces), with the addition of 5 mM La^{3+} (middle traces) and after washing out the La^{3+} (lower traces). Holding potential, −40 and +40 mV in each panel, as marked. The closed state in all traces is marked by the thin line. *b*, Activity induced in an outside-out (O/O) patch by breaking from an on-cell (O/C) patch recording into a whole-cell (W/C) recording while holding the pipette potential at 0 mV. Upper left trace, record of a 10-mV voltage jump applied to the on-cell patch immediately before break-through. The resistance was about 20 GΩ. Upper right trace, response to a 10-mV voltage jump immediately after breaking through to the whole-cell mode. The resistance decreased to ~400 MΩ. Lower traces, continuous recording from the hippocampal outside-out patch. Whole-cell recording from the photoreceptor commenced at a time indicated by the arrow in the second trace ~50 ms before the first event. Bottom trace, record from the outside-out patch 820 ms after the end of the previous trace. Holding potential of the patch, −40 mV. Holding potential of the photoreceptor pipette, 0 mV. Time calibration for on-cell and whole-cell voltage-jump traces is 10 ms.

exhibited any sensitivity to applied acetylcholine at concentrations ranging from 0.1 to 10 μM. On this basis, we conclude that all classes of turtle photoreceptors can release EAAs. These measurements do not rule out the possibility of co-release of another neurotransmitter. But, given the paucity of evidence that supports a role for GABA, acetylcholine or catecholamines, the preponderance of results with EAA agonists and antagonists on the second-order cells[1,2], the demonstration of EAA-uptake mechanisms[20], the evidence for glutamate immunoreactivity[21] in turtle cones, and the results of the study reported here, a strong case can be made to implicate EAAs as the photoreceptor neurotransmitter. □

SINCE the isolation of an HIV-2-related virus from captive macaques (SIV_{MAC})[1,2], the origin of human immunodeficiency viruses, a much debated subject[3-9], has been attributed to monkeys[3,4]. The sequence of SIV_{AGM}, which is derived from a naturally infected African green monkey, shows equal relatedness to HIV-1 and HIV-2, suggesting that the derivation of these viruses from SIV_{AGM} is unlikely. Recent sequence analysis of SIV from a captive sooty mangabey (SIV_{SM}), however, shows its close relatedness to HIV-2 and SIV_{MAC}, indicating a possible origin of HIV-2 and SIV_{MAC} from SIV_{SM} (refs 4, 7, 9). We report here the sequence of a novel simian lentivirus, SIV_{MND}, isolated from a wild-caught mandrill in Africa[10]. It is distinct from the three other main groups, HIV-1, HIV-2/SIV_{MAC}/SIV_{SM} and SIV_{AGM}, and therefore represents a fourth main group of primate lentiviruses. Phylogenetic analysis indicates that these four main virus groups might have diverged from a common ancestor at about the same time, long before the spread of AIDS in humans.

We have previously isolated a simian immunodeficiency virus, SIV_{MND}, from healthy mandrills, *Papio* (*Mandrillus*) *sphinx*, from Gabon in western equatorial Africa, and shown by hybridization analysis that it is a new lentivirus differing from all known HIV and SIV group viruses. We have obtained molecular clones from extrachromosomal closed circular DNA of SIV_{MND}(GB-1), one of two SIV_{MND} isolates. A nearly full-length clone, pSMH103, containing an insert of about 9 kb (kilobases) was used for sequencing by the Sanger method[11]. As the pSMH103 clone lacked a small *Xba*I-*Xba*I fragment of the *pol* gene, the sequence of this fragment (nucleotides 3,536 to 3,691) was obtained from another clone of SIV_{MND}(GB-1) (pSMH21) containing a 5 kb *Sac*I-*Sac*I fragment.

The nucleotide sequence of SIV_{MND} RNA consists of 9,215 bases. In addition to the *gag*, *pol* and *env* genes, open reading frames corresponding to the *vif*, *vpr*, *tat*, *rev* and *nef* genes can be found in the SIV_{MND} genome (Fig. 1), as with the primate lentiviruses reported previously[2,4,12-14]. This virus does not, however, contain open reading frames corresponding to *vpu*, identified in HIV-1 (ref. 13), or *vpx*, found in HIV-2 (ref 14), SIV_{MAC}[2], SIV_{SM}[4] and SIV_{AGM}[12].

The long terminal repeat (LTR) of SIV_{MND} consists of 796 base pairs (bp), and the lengths of its internal domains U3, R and U5 are estimated as 521, 175 and 100 bp, respectively. Sequences homologous to enhancers containing the κB motif[15] and Sp1 binding sites[15] are found upstream of the TATA box in the U3 region. In the R region, the sequence homology of SIV_{MND} with known HIVs and SIVs is low, but the RNA transcribed between nucleotides 20 and 116 still has the potential to form the stem-loop structure of the *trans*-activation-responsive (*tar*) region[17].

The *gag* open reading frame of SIV_{MND} encodes 502 amino acids and its relative molecular mass (M_r) is calculated as 56,500 (56.5K). This precursor protein may be cleaved into capsid protein, identified as p26 in SIV_{MND} virion proteins[10], amino-terminal matrix protein and carboxy-terminal nucleocapsid protein The overall sequence homologies of the *gag* precursor of SIV_{MND} to those of all the five virus isolates, BRU of HIV-1 (ref. 13), ROD of HIV-2 (ref. 14), 142 of SIV_{MAC}[2], F236 of SIV_{SM}[4] and TYO-1 of SIV_{AGM}[12], are 49.2%, 48.4%, 52 0%, 50.2% and 48.2%, respectively (Table 1).

The *pol* open reading frame of SIV_{MND} with the potential to code 1,009 amino acids (115K) probably encodes the protease, reverse transcriptase and integration protein, in that order. The p66 and p55 of the reverse transcriptase and the p31 of the integration protein were identified in SIV_{MND} virion proteins[10]. The consensus sequence of Asp-Thr-Gly, the active site of aspartic protease, which is common to most animal retroviruses[18], is also found in this virus at nucleotides 2,000-2,008. Of the open reading frames of SIV_{MND}, that of *pol* shows the highest sequence homology (56.8% to 58.2%) with those of known HIVs and SIVs (Table 1).

The *env* open reading frame of SIV_{MND} encodes a precursor that is cleaved into a surface protein (SU) and transmembrane protein (TM). The calculated molecular weights of the non-glycosylated forms of SU and TM are 59.7K and 38.6K, respec-

SIV_{MND} compared with	*Gag*	*Pol*	*Env.* SU*	*Env.* TM†	*Vif*	*Vpr*	*Tat*	*Rev*	*Nef*
HIV-1	49 2	57.1	28.8	36 9	35 4	38.5	36 7	29.5	36.9
HIV-2	48.4	56.8	34 5	37 4	39.9	35 5	34 7	25.8	35 6
SIV_{MAC}	52 0	57.4	33 2	38 1	40.7	34 9	35.0	32 6	42.1
SIV_{SM}	50.2	57.5	33 2	40.4	39 2	38 0	36 7	34 4	40 1
SIV_{AGM}	48 2	58.2	30 0	39 5	39.4	—	42 4	31.1	39 3

Numbers indicate per cent homologies of SIV_{MND} with HIV-1(BRU)[13], HIV-2(ROD)[14], SIV_{MAC}(142)[2], SIV_{SM}(F236)[4] and SIV_{AGM}(TYO-1)[12] within the aligned region using Wilbur and Lipman programs[34] (parameters KTPL 2-3, DEL 3-4). * Surface, and † transmembrane proteins of *env* gene product

tively The TM protein is considered to be reduced in size to 29.1K by the in-frame stop codon at nucleotide 8,124, because the size of the putative TM in SIV_{MND} virion proteins is ~30K[10]. The in-frame stop codon in SIV_{MND} is downstream of those in HIV-2 (ref. 14), SIV_{MAC}[2] and SIV_{AGM}[12]. There are 20 potential N-glycosylation sites on the SIV_{MND} *env* protein, 16 sites in SU and 4 in TM. Of these sites, 8 to 10 are located in the same position as those in HIV-1 (ref. 13), HIV-2 (ref. 14), SIV_{MAC}[2], SIV_{SM}[4] and SIV_{AGM}[12]. The homology of the SIV_{MND} *env* protein with known HIV and SIV group viruses is low; 28.8%-34.5% for SU and 36.9%-40.4% for TM (Table 1). There are 28 cysteine residues in the SIV_{MND} *env* protein, of which 18-21 are in the same position as those in HIV-1, HIV-2, SIV_{MAC}, SIV_{SM} and SIV_{AGM}. Also, 17 of them are completely conserved in all six virus groups. Based on the alignment with paramyxovirus sequences, a hydrophobic stretch at the amino terminus of TM, Phe-Leu-Gly-Phe-Leu, which could be related to the membrane fusion activity of TM, is completely conserved in all known HIV and SIV group viruses[19] The corresponding sequence of SIV_{MND}, Ile-Leu-Gly-Leu-Leu, at nucleotides 7,386-7,400 is not coincident with that of other viruses, but shows a similar hydrophobic profile (data not shown). In this biologically inactive clone SMH103, the *env* and the first coding exon of *rev* are in the same phase, probably as a result of one base (C) being absent between nucleotides 5,773 and 5,776.

It is conceivable that the *tat* and *rev* proteins of SIV_{MND} are also translated for spliced subgenomic messenger RNAs, as shown in HIV-1 (refs 20, 21). In these proteins, amino-acid homology between SIV_{MND} and known HIV and SIV group viruses is low (Table 1). The seven cysteine residues encoded between nucleotides 5,579 and 5,629 in the SIV_{MND} genome, however, which are important for forming the metal-linked dimer[22] of *tat* protein, are found at the same positions as those in all known HIV and SIV group viruses[2,4,12-14]. The stretches of basic amino acid residues encoded by *tat* (corresponding to nucleotides 5,669-5,698) and *rev* (corresponding to nucleotides 8,006-8,047), which probably constitute parts of nucleic acid-binding sites[22], are also found in SIV_{MND}. Also, the GTP-binding site-related sequence, demonstrated in the *nef* protein of HIV-1 (ref. 23), is also found in SIV_{MND} (nucleotides 8,515-8,601), although it shows low amino-acid homology with the sequences of other HIV and SIV group viruses.

Comparison of the genomic organization of HIV-1, HIV-2, SIV_{MAC}, SIV_{SM}, SIV_{AGM} and SIV_{MND} indicates that in addition to the *gag*, *pol* and *env* genes, *vif*, *tat*, *rev* and *nef* are common to all six virus groups and are fundamental components of primate lentiviruses. The *vpu* gene in HIV-1 (ref. 24), *vpx* in HIV-2 (ref. 25), SIV_{MAC}[25], SIV_{SM}[4] and SIV_{AGM}[12], and *vpr* in HIV-1 (ref. 13), HIV-2 (ref. 14), SIV_{MAC}[2], SIV_{SM}[4] and SIV_{MND}, however, are not present in all primate lentiviruses; these genes are also inessential for virus replication[24,25].

The phylogenetic tree constructed by nucleotide sequence alignment of the reverse transcriptase and integration protein in *pol* (Fig. 2) clearly indicates that the SIV_{MND} virus described here belongs to the *Lentivirinae* subfamily of retroviruses and has evolved from a common ancestral virus of primate lentiviruses just before divergence of HIV-1 from HIV-2. Although the branching order is slightly different in phylogenetic trees based on *gag* gene and other sequence comparisons (data not shown), these phylogenetic trees indicate that the four main groups of primate lentiviruses, SIV_{MND}, SIV_{AGM}, HIV-2/SIV_{MAC}/SIV_{SM} and HIV-1, diverged from a common ancestral virus at about the same time.

SIV_{MAC} and SIV_{SM} are genetically very close to HIV-2 (refs 2, 4), and recent reports[26,27] indicate considerable genetic variability in HIV-2 isolates. Therefore, SIV_{MAC}, SIV_{SM} and HIV-2 can be considered as one virus group, as shown in Fig. 2. Large scale serological surveys of non-human primates[28,29] has shown that many macaques in natural conditions are seronegative, whereas the observed sooty mangabeys (*Cercocebus atys*), indigenous to West Africa, were seropositive for SIV_{MAC}[3,29]. From this observation, Hirsch *et al.*[4] suggested that SIV_{SM}-infected macaques in captivity, and humans in West Africa, evolving as SIV_{MAC} and HIV-2, respectively. As the SIV_{SM} isolate sequenced originated from a captive animal in the Delta Primate Center in the United States, however, it is necessary to determine the sequence of SIV obtained from a sooty mangabey in the wild.

Several recent studies on molecular evolution have suggested that the *gag* and *pol* genes of HIV-1 have evolved at approximate rates of 10^{-3} nucleotide substitutions per site per year[30-32]. By extrapolation of these substitution rates to the time of evolution of all primate lentiviruses, we estimate that the four main lentivirus groups diverged several hundred years ago These substitution rates, however, are based on a comparison of multiple isolates within only the HIV-1 group[30-32], and so are not directly applicable to all primate lentiviruses, which are highly divergent in species specificity and pathology.

The SIV_{MND}(GB-1) isolate sequenced in this study originated from a wild mandrill, because the animal was already seropositive when it was brought to Franceville Primate Center in Gabon immediately after its capture in the wild[10]. The possibility that this mandrill was infected by other monkey species in the wild is unlikely; other infected mandrills, although in a zoo[29], have been reported that were probably obtained from other places in Africa. Thus mandrills are almost certainly infected with SIV_{MND} in the wild. This virus apparently does not cause disease in mandrills, as in the case of SIV_{AGM}, although only a small number have been examined so far[28,29]. The SIV_{AGM}(TYO-1)

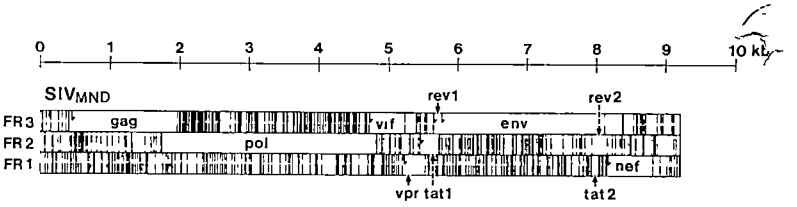

FIG 1 Organization of the SIV_{MND} genome as determined from the sequence Vertical bars represent stop codons in the three reading frames (FR1-FR3). Arrows indicate the potential AUG initiator codon of each open reading frame *Tat* 1 and 2, and *rev* 1 and 2 are open reading frames containing possible coding exons of the *tat* and *rev* genes

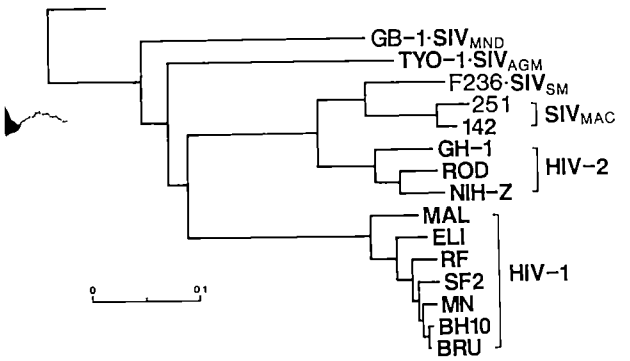

FIG 2 Phylogenetic tree showing the evolutionary relationship of SIV$_{MND}$ and known primate lentiviruses The tree was constructed by the neighbour-joining method[35] after alignment of the nucleotide sequences of the reverse transcriptase and the integration protein in the *pol* gene The viral sequences used in this study were as follows GB-1 isolate of SIV$_{MND}$ in this study, TYO-1 isolate of SIV$_{AGM}$[12], Delta/F236 isolate of SIV$_{SM}$[4], 251[36] and 142[2] isolates of SIV$_{MAC}$, GH-1[27], ROD[14] and NIH-Z[26] isolates of HIV-2, MAL[37], ELI[37], RF[38], SF2[39], MN[40], BH10[41] and BRU[13] isolates of HIV-1. The sequences of ovine visna lentivirus (VISNA)[42] and equine infectious anaemia virus (EIAV)[43] were used as reference species of lentiviruses in the calculation to make the position of the root in the tree clear Horizontal distances from each branch are proportional to the number of amino-acid substitutions. The scale bar indicates 0 1 substitutions per site

isolate can be considered as a representative strain of SIV$_{AGM}$, which is highly endemic in African green monkeys in the wild[12,28,33]. Our sequence analysis of SIV$_{MND}$ and SIV$_{AGM}$ suggests that several species of African non-human primates have harboured SIV for a long time and that these SIVs are specific to their natural hosts. □

T CELLS expressing the $\alpha\beta$ T-cell receptor (TCR) for antigen can elicit anti-idiotypic antibodies specific for the TCR that regulate T-cell function[1–4]. Defined sequences of the TCR, however, have not been used to elicit specific antibodies and the role of cellular immunity directed against TCR determinants has not been studied. We immunized Lewis rats with a synthetic peptide representing a hypervariable region of the TCR Vβ8 molecule. Subsequent induction of experimental autoimmune encephalomyelitis, a paralytic disease of the central nervous system mediated primarily by Vβ8$^+$ T cells specific for myelin basic protein[5,6] was prevented. T cells specific for the TCR Vβ8 peptide conferred passive protection against the disease to naive rats, apparently by shifting the predominant T-cell response away from the major encephalitogenic epitope of basic protein. This is the first report demonstrating the use of a synthetic TCR V-region peptide to induce specific regulatory immunity and has important implications for the regulation of human disease characterized by common TCR V-gene usage.

In a previous study[6], we reported the complete nucleotide and deduced amino-acid sequence for the rearranged rat TCR α- and β-chain genes (with sequence homology to the mouse Vα2 and Vβ8 families respectively) used in response to the major encephalitogenic epitope of basic protein, namely residues 72–89. Within the TCR Vβ8 region, we identified and synthesized a 21-amino acid sequence that included the second complementarity determining region (CDR2) and was predicted to be immunogenic for T cells[7,8]. A control peptide was synthesized from the corresponding region of a different TCR Vβ sequence that was homologous to the mouse Vβ14 family[9].

Immunization of Lewis rats with the TCR Vβ8 peptide but not with the TCR Vβ14 peptide or saline prevented completely the induction of experimental autoimmune encephalomyelitis (EAE) (Table I). The Vβ8-peptide-immunized rats developed both specific antibodies [0.63 optical density (OD) units to the Vβ8 peptide compared with 0.02 OD units to the control peptide at a 1:200 dilution of serum analysed by enzyme-linked immunosorbent assay (ELISA)] and delayed type hypersensitivity (DTH) responses 17/100 mm = 0.17 mm ear swelling to 50 μg TCR Vβ8 peptide compared with 0/100 mm = 0 00 mm swelling to the control peptide. The Vβ14 peptide also induced specific immunity in rats injected with the Vβ14 peptide even though it did not confer protection against EAE. Lymph node cells isolated from the protected rats responded to the TCR Vβ8 peptide as well as to guinea-pig basic protein (GPBP) and PPD (purified protein derivative of *Mycobacterium tuberculosis*) (Table 2).

T-cell lines were selected from the lymph nodes of the protected rats that responded specifically to the Vβ8 but not to the Vβ14 peptide (Table 2). The TCR Vβ8 peptide-specific T cells

Rats were immunized subcutaneously (s c) with 400 μg TCR Vβ8 peptide in CFA containing 1 mg *M tuberculosis*, and were challenged s c with 50 μg GPBP in CFA at the same time or with 100 μg encephalitogenic peptide after 30 days Twenty days after simultaneous challenge, draining lymph nodes were removed and a single-cell suspension was tested in microtitre wells (5×10^5 cells per well) for response to antigens and mitogens The remainder of the cells were stimulated in 6-cm diameter Petri dishes with either TCR peptide or GPBP (50 μg ml^{-1}) for 3 days and transferred into interleukin-2 (IL-2) rich medium for an additional 4 days These cells (2×10^4 per well) were restimulated with antigens and mitogens in the presence of irradiated thymic accessory cells. Stimulation in the presence of TCR peptide or GPBP was carried out in the presence of 2 μg per well monoclonal antibodies. Underlined values indicate significant stimulation ND, not done

TABLE 3 Response of TCR Vβ8 peptide-specific T-cell line to attenuated Vβ8 (+) or (−) T cells

GPBP (S72–89)*	+	31±3
GPBP (55–74)*	−	8±1

T-cell-line cells were irradiated (2,500 R) and 2×10^4 cells were mixed in the absence of additional accessory cells with 2×10^5 TCR specific T cells for 3 days, the last 18 h with [^{3}H]Thy. The cells were harvested and [^{3}H]Thy uptake assessed by liquid scintillation Background proliferation of irradiated T cells specific for GPBP (S72–89) and GPBP (55–74) was 130 and 220 c p m respectively

* TCR V gene use for these T-cell lines was described prevously[11].

were strongly positive by immunofluorescence for the CD4 marker and weakly positive for the CD8 marker, but the response to the Vβ8 peptide was restricted only by MHC class I molecules.

A GPBP-specific T-cell line was also selected from protected rats immunized with both the TCR Vβ8 peptide and GPBP. This line had an uncharacteristically low response to the encephalitogenic 72–89 peptide relative to GPBP[10]. Once selected and activated, GPBP-specific T-cell-line cells from TCR-peptide-protected rats were encephalitogenic (hind-leg paralysis with 10 million cells in all 3 rats), indicating that Vβ8 peptide immunization did not result in the deletion of encephalitogenic T-cell precursors.

Mixing of the TCR Vβ8-specific and BP-specific T cells did not impair the response to GPBP, even in the presence of the TCR peptide (Table 2). The presence of TCR Vβ8-specific T cells, however, caused, an increased response to all of the

peptides of GPBP except the encephalitogenic 72–89 sequence. The TCR peptide-specific T cells therefore seemed to alter the peptide recognition pattern of GPBP reactive T cells and indicated the possibility of cell–cell interactions.

Direct interactions could also be demonstrated. The addition of irradiated Vβ8$^+$ target cells induced significant proliferation by the TCR-specific T-cell line in the absence of additional accessory cells, whereas Vβ8$^-$ T cells[11] did not (Table 3), indicating the direct recognition of the TCR sequence on the target T-cell surface. The TCR peptide-specific T cells, however, were not cytotoxic for the BP-reactive target cells (data not shown).

The protective ability of Vβ8 peptide-specific T cells was established by adoptive transfer. Rats injected with as few as 10 million Vβ8 peptide-specific T cells did not develop EAE (Table 4). The transferred protection appeared to be T-cell mediated, as we were unable to detect Vβ8 peptide-specific antibodies in the serum of protected rats. DTH results (Table 4) indicated that the adoptively transferred T cells could prevent the induction of EAE without compromising T-cell recognition of other antigens.

The ability of Vβ8-peptide-specific T cells to alter the response patterns of GPBP specific T-cell lines *in vitro* and to protect naive rats from EAE and reduce DTH reactions *in vivo* indicated that the pattern of response to BP epitopes might be altered in rats protected by TCR-peptide-specific T cells. As shown in Table 5, lymph-node cells (LNC) from the EAE-protected animals responded well to the TCR peptide, but poorly to GPBP and the encephalitogenic 72–89 peptide of GPBP compared to LNC from the control group. By contrast, LNC from the protected group showed a significant response to the 87–99 peptide of BP, whereas LNC from the control group had no response to this peptide (Table 5). The selection of a TCR-Vβ8-peptide-specific T-cell line from the lymph nodes of adoptively protected rats (Table 5) indicated that TCR-peptide-specific T cells had migrated to and persisted in the lymph nodes that drained the site of GPBP injection.

These results demonstrate for the first time the use of a synthetic peptide from the CDR2 region of the TCR to induce Vβ8-specific regulatory T cells that prevent the induction of EAE. Computer modelling of ternary interactions among TCR chains, antigenic peptides, and MHC restriction molecules is consistent with CDR involvement in peptide/MHC binding when the TCR is folded in an energetically favourable conformation[12,13]. The indisputable regulatory effects of T cells specific for CDR2 support the notion that this region has biological importance.

It seems unlikely that the responder T cell is interacting directly with the functional TCR Vβ8 molecule on the target T-cell surface. Indeed, it is conceivable that endogenous TCR peptide could be 'processed' and expressed preferentially on the T-cell surface in association with class I molecules[14]. If a natural form of the TCR peptide is associated with the MHC on the T-cell surface, the interacting TCR-specific T cell could interfere with normal activation by BP.

Vaccination with attenuated T cells has provided indirect evidence that protection against autoimmunity may include T-cell recognition of TCR[15–20]. These data indicated that protective immunity was induced against target structures shared by different T-cell clones specific for the same disease-inducing epitope, but did not implicate the TCR directly. The immunogenicity and immunoregulatory activity demonstrated here of a defined region of the TCR Vβ8 chain expressed by encephalitogenic T cells is an important step forward in understanding anti-idiotypic regulation, and provides a clear explanation for the protective effects of the vaccination approach.

The induction of anti-idiotypic antibodies directed against TCR determinants expressed on the surface of intact T cells has played a crucial role in the identification and function of the TCR itself[1–4]. Two of the TCR Vβ8 specific monoclonal antibodies, F23.1 and KJ16, can inhibit EAE in the mouse, which also uses the TCR Vβ8 gene in response to BP[21,22]. Our approach using a synthetic peptide to induce TCR-peptide-specific antibodies may be of value in producing a variety of highly specific antibodies for assessing sequences important in TCR function. The potential regulatory properties of antibodies raised to the Vβ8 peptide will be addressed in a separate study.

TCR peptide vaccination may have application in human autoimmune or malignant conditions that are characterized by common TCR V-gene usage This approach would seem to have clear advantages over other approaches such as tolerance induced with potentially pathogenic target autoantigens, or whole-cell vaccination which is 'individual' specific and complicated by the presence of extraneous cell-surface antigens. □

TABLE 5 Specificity of T-cell lines from rats protected from EAE by Vβ8 peptide-specific T cells

Binding activities of a repertoire of single immunoglobulin variable domains secreted from *Escherichia coli*

E. Sally Ward, Detlef Güssow, Andrew D. Griffiths, Peter T. Jones & Greg Winter*

MRC Laboratory of Molecular Biology, Cambridge CB2 2QH, UK

IN antibodies, a heavy and a light chain variable domain, VH and VL, respectively, pack together and the hypervariable loops on each domain contribute to binding antigen[1-4]. We find, however, that isolated VH domains with good antigen-binding affinities can also be prepared. Using the polymerase chain reaction[5], diverse libraries of VH genes were cloned from the spleen genomic DNA of mice immunized with either lysozyme or keyhole-limpet haemocyanin. From these libraries, VH domains were expressed and secreted from *Escherichia coli*. Binding activities were detected against both antigens, and two VH domains were characterized with affinities for lysozyme in the 20 nM range. Isolated variable domains may offer an alternative to monoclonal antibodies and serve as the key to building high-affinity human antibodies. We suggest the name 'single domain antibodies (dAbs)' for these antigen binding demands.

We have analysed the interactions with antigen of individual domains of the anti-lysozyme antibody, D1 3 (ref. 1). The VH domain was expressed in *E. coli* and secreted into the periplasm[6,7], alone or in association with the Vκ domain (fig. 1). Analysis of culture medium, by passage through a lysozyme-Sepharose affinity column[8], followed by SDS-PAGE[9] revealed that both the isolated VH domain, or the associated Fv fragment, could bind to lysozyme, and could be purified to homogeneity in a single step, with yields of ~200 μg l^{-1} and 10 mg l^{-1}, respectively The VH domain appears to be monomeric by FPLC (Pharmacia, Superose 12 column). The N-terminal sequences of both domains were checked by gas-phase protein sequencing[10,11].

As shown in Table 1, the affinity of Fv fragment for lysozyme and the stoichiometry of binding of the VH domain to lysozyme were determined by titration using fluorescence quench techniques. The affinity of VH domain for lysozyme was determined

TABLE 1 Affinities of Fv fragment and VH domains for hen egg lysozyme

	Stoichiometry	Affinity (nM)	k_{on} ($M^{-1}s^{-1}$)	k_{off} (s^{-1})	k_{off}/k_{on} (nM)
Fv-D.1.3	ND	3	1.9×10^{6}	ND	ND
VH-D1 3	1 2	ND	3.8×10^{6}	0 075	19
VH3	ND	ND	2.9×10^{6}	0 036	12
VH8	ND	ND	3.3×10^{6}	0 088	27

Cultures of 500 ml were grown and induced (see Fig 1 methods), and the supernatant passed through a 0.45 μm filter (Nalgene), then through a 5 ml lysozyme-Sepharose affinity column. After washing with phosphate buffered saline (PBS), the Fv fragment or VH domains were eluted with 50 mM diethylamine, and analysed for purity by SDS-PAGE[9] The proteins were titrated with lysozyme at 25 °C using fluorescence quench (Perkin Elmer LS 5B Luminescence Spectrometer)[27] to determine the number of active binding sites, to measure the affinity of the Fv fragment and the stoichiometry of binding of the VH domain (mole lysozyme per mole domain) The concentration of the VH domain of the D1 3 antibody was determined by hydrolysis followed by quantitative amino-acid analysis The kinetics of lysozyme binding were determined by stopped-flow (HI Tech Stop Flow SHU) at 20 °C under pseudo-first order conditions with binding sites in five to ten fold excess over lysozyme[28] For the kinetics, the concentration of binding sites, not protein, was measured ND, not determined. k_{on} is the second order rate constant for association, and k_{off} is the first order rate constant for dissociation

from the kinetics of binding. The affinity of the Fv fragment (3 nM) is similar to the parent antibody (2 nM). The VH domain binds lysozyme tightly in an equimolar complex with an affinity for lysozyme (19 nM) which is only 10-fold weaker. Separated heavy and light chains have previously been identified with antigen[12] or hapten binding activities[13] although the affinities were poor, with no evidence for binding by single chains[13,14] rather than dimers[15].

In the D1.3 antibody, lysozyme interacts extensively with both domains, and forms three hydrogen bonds to the Vκ domain, and nine hydrogen bonds to the VH domain. Binding of lysozyme buries ~300 $Å^2$ of Vκ domain away from solvent, and 400 $Å^2$ of the VH domain[1]. Our results show, however, that the Vκ domain makes only a small net contribution to the energetics of binding. This is surprising as the removal of a single hydrogen bond[16] or a single van der Waals contact[17] can lead to tenfold loss in affinity. The VH domain presumably binds to lysozyme in a similar way to the antibody and this is consistent with inhibition of binding of the Fv fragment by the VH domain (data not shown, but see Fig. 1 legend). It is possible that the whole surface of interaction might reorientate slightly, perhaps by rocking on side chains, to create a new set of contacts[18].

The result prompted us to obtain VH domains with antigen-binding activities from antibody-producing cells. Previously we have demonstrated the cloning of immunoglobulin variable regions from hybridoma mRNA for expression of chimaeric antibodies, using the polymerase chain reaction (PCR)[5,19]. We now used PCR to amplify the rearranged VH genes from the spleen DNA of a mouse immunized with lysozyme (Fig. 2). The amplified DNA was cloned into the vector M13VHPCR1 (ref. 19) for sequencing. The complete sequences of 48 VH gene clones were determined (data not shown). All but two of the mouse VH gene families[20] were represented, with frequencies of: VA (1), IIIC (1), IIIB (8), IIIA (3), IIB (17), IIA (2), IB (12) and IA (4). In 30 clones the D segments could be assigned to families SP2 (14), FL16 (11) and Q52 (5), and in 38 clones the JH minigenes to families JH1 (3), JH2 (7), JH3 (14) and JH4 (14) The different sequences of CDR3 marked each of the 48 clones as unique. Nine pseudogenes and 16 unproductive rearrangements were identified; of the clones sequenced, 27 have open reading frames. Clearly we can generate a diverse repertoire of VH genes using PCR, but cannot rule out a systematic bias due to our choice of primers and hybridization conditions. VH gene libraries have also been generated using PCR

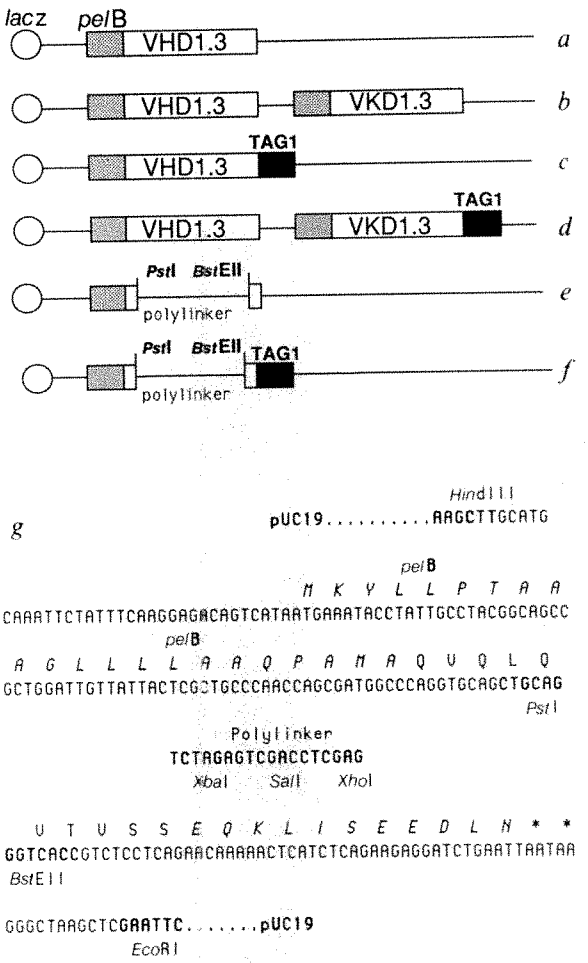

FIG. 1 Vectors for expression of VH and Vκ domains. Scheme showing inserts in expression vectors. *a*, pSW1-VHD1.3; *b*, pSW1-VHD1.3-VKD1.3; *c*, pSW1-VHD1.3-TAG1; *d*, pSW1-VHD1.3-VKD1.3-TAG1; *e*, pSW1-VHPOLY; *f*, pSW1-VHPOLY-TAG1; and *g*, nucleotide sequence of pSW1-VHPOLY-TAG1 insert. The amino acid sequence of the pelB leader and TAG1 are shown in italics.

METHODS. The vectors were assembled from pUC19 (ref. 29), synthetic oligonucleotides encoding the pelB signal sequence[30] peptide tag[24], restriction site polylinker, and (as appropriate) cloned cDNA of the VH and Vκ domains of the D1.3 antibody (M. E. Verhoeyen, C. Berek and G. W., unpublished data). Recombinant plasmids were transformed into *E. coli* BMH71-18 (ref. 31), colonies selected on TYE plates[32] with 100 μg ml^{-1} ampicillin (AMP) and 1% glucose (GLU), and toothpicked into 200 μl 2×TY medium[32], AMP, GLU in wells of ELISA plates. Colonies were grown at 37 °C for 16–24 h. Cells were pelleted, washed twice in 50 mM NaCl (200 μl) and resuspended in 200 μl 2×TY medium, AMP and 1 mM isopropylthiogalactoside (to induce expression) and grown for a further 16–24 h. The cells were cooled, pelleted and supernatants screened for secretion of VH domains (by western blotting) or antigen binding activity (by direct ELISA). Western blot methods were essentially as in ref. 22: supernatant (10 μl) from the cultures was subjected to SDS-PAGE[9] and proteins then transferred electrophoretically to nitrocellulose. The VH domains were detected by means of the peptide tag with 9E10 antibody[24]. However, the tag can be lost by proteolytic cleavage in culture, especially after prolonged growth of the bacteria. Bound antibody was detected using horseradish peroxidase conjugated rabbit anti-mouse antibody at a dilution of 1:1000. 4-chloro-1-naphthol (Sigma) was used as the peroxidase substrate. For direct ELISA, wells of Falcon ELISA plates were coated with antigen in phosphate buffered saline (PBS) overnight (3 mg ml^{-1} lysozyme, or 50 μg ml^{-1} KLH), then blocked with 2% skimmed milk powder in PBS for 2 h at 37 °C. Bacterial supernatant was added and incubated at 37 °C for 2 h. D1.3-VH domains were detected with rabbit polyclonal antiserum raised against the D1.3 Fv fragment, using peroxidase conjugated goat anti-rabbit immunoglobulin. Tagged VH domains were detected as described in western blotting except with 2,2′-azino-bis (3-ethylbenzthiazoline-6-sulphonic acid) as the peroxidase substrate. Three washes of 0.05% Tween 20 in PBS, were followed by three washes of PBS between each step (only PBS washes before addition of blocker or bacterial supernatants). Competition ELISA was as above except that the binding of the Fv fragment tagged on the Vκ domain was competed against by untagged VH domain.

from mRNA of human peripheral blood lymphocytes (J. Marks, D.G. & G.W., unpublished data) and from mRNA of mouse spleen[21].

Amplified DNA was then cloned for expression into a vector which incorporates a C-terminal peptide tag to facilitate detection of expressed VH domains (Fig. 1*f*). Bacterial supernatants were analysed by SDS-PAGE followed by western blotting[22], and bands of the expected size ($M_r \approx 14{,}000$) were detected for 14 of the 17 clones by probing with antibody directed against the tag[23,24]. To screen for lysozyme binding activities, about two thousand colonies were toothpicked in groups of five into wells of enzyme-linked immunosorbent assay (ELISA) plates, and the supernatants tested for binding to lysozyme-coated plates. Twenty-one supernatants were shown to have lysozyme-binding activity, and some of the corresponding individual clones were prepared.

Two of the clones (VH3 and VH8) with lysozyme-binding activities were sequenced (Fig. 3). They belonged to the same VH-gene (Kabat IIB) families and D-segment families (FL16) but had different J segments (JH2 and JH4). There were only six amino-acid differences between the (unrearranged) VH genes, but the sequences of CDR3 were completely different. The VH domains were purified and affinities for lysozyme determined (Table 1). The affinities, in the 20 nM range, are similar to those of the VH domain of the D1.3 antibody. To check the specificity of binding, the three VH domains were also screened for binding to four other purified proteins (bovine serum albumin, insulin, keyhole-limpet haemocyanin (KLH) and cytochrome c), and to foetal calf serum, milk powder and plastic of microtitre plates. No binding was detected. (However, other cross-reactive VH domains have been found.) The VH-D1.3, VH3 and VH8 domains appear to bind to the same region of lysozyme, as they inhibit the binding of the D1.3 Fv fragment.

To test whether VH domains with other binding activities

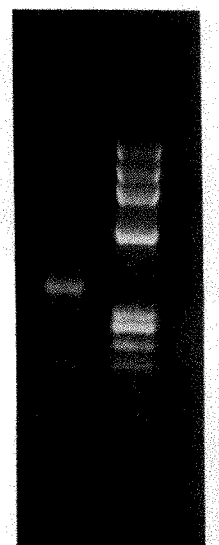

FIG. 2 PCR amplification of VH genes from mouse genomic DNA. Agarose gel electrophoresis of amplified mouse VH DNA (left-hand lane) with markers ΦX174 *Hae*III fragments (right-hand lane). METHODS. Balb/c mice were hyperimmunized with hen egg-white lysozyme (100 μg antigen, intraperitonally on day 1 in complete Freunds adjuvant and on day 14 in incomplete Freunds adjuvant; followed by 50 μg antigen intravenously on day 35; mice were killed on day 39) or similarly with KLH. DNA was prepared from the spleen and the rearranged mouse VH genes were amplified. Conditions were chosen to minimize annealing between the 3′ ends of the two primers. The sample (50–100 μl) included 50–200 ng DNA, VH1FOR-2 (5′ TGA GGA GAC GGT GAC CGT GGT CCC TTG GCC CC 3′) and VH1BACK primers[19] (25 pm of each) 250 μM of each dNTP, 10 mM Tris-HCl pH 8.8, 50 mM KCl, 1.5 mM $MgCl_2$, 100 μg ml^{-1} gelatine. The sample was overlaid with paraffin oil, heated to 95 °C for 2 min, 65 °C for 2 min, and then to 72 °C; *Taq* polymerase (2 units, Cetus) was added after the sample had reached the elongation temperature and the reaction continued for 2 min at 72 °C. The sample was subjected to a further 29 rounds of temperature cycling using the Techne PHC-1 programmable heating block. The amplified DNA was digested with *Pst*I and *Bst*EII and fractionated on an agarose gel. A band of about 350 base pairs was extracted and cloned.

could be made, and whether immunization was necessary, a new VH-gene library was prepared from a mouse immunized with KLH. Culture supernatants from the two libraries were tested for binding to lysozyme or to KLH. The first library (immunization with lysozyme) had yielded 21 supernatants with lysozyme- and two with KLH-binding activities, whereas the second library (immunization with KLH, screening ~2,000

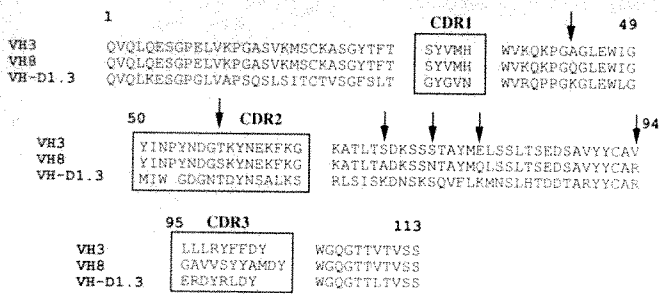

FIG. 3 Sequences of VH domains with lysozyme-binding activities. The sequences of the VH domains are aligned with that of the D1.3 antibody.

colonies) yielded two supernatants with lysozyme- and 14 with KLH-binding activities. We conclude that VH domains can be derived, preferably after immunization, with binding activities to lysozyme and KLH and presumably other antigens. VH domains lack the cavity which can be formed with the Vκ partner however, and this might bias the binding activities against hapten binding[2,15]. The affinity of the VH domains (20 nM or 5×10^7 M^{-1}) for lysozyme lies within the range expected for the affinities of monoclonal antibodies for protein antigens, and can be improved by site-directed mutagenesis (unpublished data).

VH domains with binding activities can be generated in a matter of days without recourse to tissue culture, and may also have other advantages over monoclonal antibodies. For example, the smaller molecule should penetrate tissues more readily, could permit the blocking of 'canyon' sites on viruses[25,26] and allow epitope mapping at higher resolution. However, VH domains are relatively 'sticky', presumably due to the exposed hydrophobic surface normally capped by the Vκ or Vλ domains. It should be possible to design VH domains with improved properties. We also envisage that VH domains with binding activities could serve as the building blocks for making Fv fragments or complete antibodies. For example, such VH domains could be co-expressed with a repertoire of Vκ domains, derived by PCR amplification of Vκ genes[19] and screened for association of the domains and antigen binding. This approach could prove valuable for building human antibodies of therapeutic value, and even for catalytic antibodies; for example, making Fv fragments in which the VH domain binds substrate, and side chains or prosthetic groups in the Vκ partner stabilize the transition state or attack the substrate[33]. □

PROTEASE nexin-II (PN-II) is a protease inhibitor that forms SDS-resistant inhibitory complexes with the epidermal growth factor (EGF)-binding protein, the γ-subunit of nerve growth factor, and trypsin[1–3]. The properties of PN-II indicate that it has a role in the regulation of certain proteases in the extracellular environment. Here we describe more of the amino-acid sequence of PN-II and its identity to the deduced sequence of the amyloid β-protein precursor (APP)[4,5]. Amyloid β-protein is present in neuritic plaques and cerebrovascular deposits in individuals with Alzheimer's disease and Down's syndrome[6–9]. A monoclonal antibody against PN-II (designated mAbP2-1) recognized PN-II in immunoblots of serum-free culture medium from human glioblastoma cells and neuroblastoma cells, as well as in homogenates of normal and Alzheimer's disease brains. In addition, mAbP2-1 stained neuritic plaques in Alzheimer's disease brain. PN-II was a potent inhibitor of chymotrypsin with an inhibition constant K_i of 6×10^{-10} M. Together, these data demonstrate that PN-II and APP are probably the same protein. The regulation of extracellular proteolysis by PN-II and the deposition of at least parts of the molecule in senile plaques is consistent with previous reports that implicate altered proteolysis in the pathogenesis of Alzheimer's disease[4,5,10–12].

Protease nexins are protein protease inhibitors that are synthesized and secreted by various cultured extravascular cells. They form SDS-resistant complexes with certain serine proteases; the complexes then bind back to the cells and are rapidly internalized and degraded[1–3,13,14]. Protease nexin-I is a specific thrombin inhibitor when bound to the cell surface[15]. It stimulates neurite outgrowth in cultured neuroblastoma cells[16,17] and primary chick sympathetic neurons[18] and is reduced by about six-fold in Alzheimer's disease brain[19]. PN-II is unusually stable and forms complexes with target proteases even after incubation of the protein with SDS or at a pH of 1.5 (ref. 3).

We analysed the N-terminal amino-acid sequence of two peptides obtained from digestion of PN-II. Sequencing of a CNBr peptide of PN-II yielded a sequence that overlapped with the N-terminal sequence previously reported[3] (Fig. 1). Additional sequence was obtained from a PN-II peptide generated by endoproteinase Lys-C. We searched the protein-sequence database of the National Biomedical Research Foundation for sequences with identity to the known sequence of PN-II. Identity was found with the deduced sequence for APP[4,5] (Fig. 1). The only discrepancy was amino-acid residue 27 in PN-II, which we originally reported as a questionable phenylalanine[3]; there

§ To whom correspondence should be addressed.

s a histidine residue at the corresponding position in the sequence predicted from the cDNA of APP. The observed sequence identity, together with reports that certain forms of APP possess a protease inhibitory domain[5,11,12] and protease inhibitory activity[12] indicated that PN-II and APP could be the same or very similar proteins.

Cultured human glioblastoma cells and neuroblastoma cells have been shown to secrete APP[20] and to express its messenger RNA[5,12]. APP and its mRNA have also been detected in human brains[5,11,12,20]. Likewise, the immunoblots of Fig. 2*a* show that the PN-II specific monoclonal antibody mAbP2-1 recognized a protein in the culture medium of glioblastoma cells (lane 2) and neuroblastoma cells (lane 3) that seems identical to PN-II present in the culture medium of human fibroblasts (lane 1). Also, mAbP2-1 recognized a similar protein in tissue homogenates prepared from the pareital cortex of normal brain (Fig. 2*b*, lane 1) or Alzheimer's disease brain (Fig. 2*b*, lane 2). The presence of PN-II in these cell culture media and brain homogenates was also shown by the formation of complexes with ^{125}I-labelled EGF-binding protein that co-migrated with complexes formed between PN-II and EGF-binding protein (data not shown).

The antibody mAbP2-1 selectively stained neuritic plaques in tissue sections of Alzheimer's disease brain. Figure 3*a* shows that mAbP2-1 exhibited intense staining of neuritic plaques in the CA1 region of the hippocampus of a patient with Alzheimer's disease. Staining was not observed in age-matched controls (data not shown). Higher magnification of a neuritic plaque (Fig. 3*b*) showed that the staining was more pronounced at the periphery.

We tested the ability of purified PN-II to inhibit a variety of serine proteases by using spectrophotometric assays with chromogenic substrates, and found that it was a potent inhibitor of chymotrypsin (Fig. 4*a*). We have previously shown that PN-II formed SDS-resistant inhibitory complexes with EGF-binding protein, the γ-subunit of nerve growth factor and trypsin[1-3]. (Note that incubation with excess trypsin resulted in proteolysis of PN-II.) The formation of complexes between chymotrypsin and PN-II was not observed by SDS-PAGE. Stable binding of chymotrypsin to PN-II, however, was identified with a ^{125}I-labelled chymotrypsin blotting assay. The autoradiograph shown in Fig. 4*b* demonstrates that ^{125}I-labelled chymotrypsin bound to purified PN-II that had been transferred to a nitrocellulose membrane after SDS-PAGE. This assay showed that

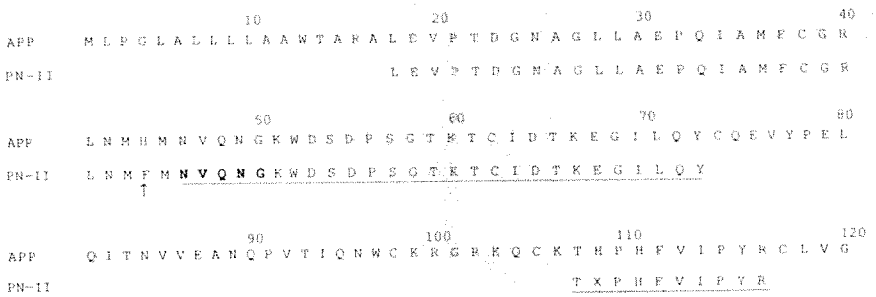

FIG. 1 Alignment of the amino-acid sequences of PN-II and APP. Identity was found in segments of the first 120 amino acids of the deduced APP sequence[4,5]. The N-terminus of PN-II starts at position 18 of APP. Underlined PN-II residues at positions 46–72 were derived from a PN-II CNBr peptide. PN-II residues at positions 46–50 shown in bold represent overlap from the N-terminal sequence of native PN-II and the N-terminal sequence of the PN-II CNBr peptide. The arrow at position 44 indicates an uncertain phenylalanine from the original N-terminal sequence of native PN-II (ref. 3) and is the only discrepancy in the alignments. Underlined PN-II residues at positions 107–116 were derived from a PN-II endoproteinase Lys-C peptide. No determination could be made for position 108.

METHODS. Purified PN-II (~2 nmol) was digested overnight with either CNBr or endoproteinase Lys-C (Boehringer). The resulting peptides were subjected to SDS-PAGE as described by Laemmli[24]. The peptides were electro-eluted from the gels onto Immobilon polyvinylidene difluoride membranes (Millipore) in a Transblot unit (BioRad Laboratories). After transfer, the membranes were stained with Coomassie Brilliant Blue R-250, de-stained and soaked in several changes of distilled water. A CNBr peptide of relative molecular mass 12,000 (M_r 12 K) and a endoproteinase Lys-C peptide of M_r 20 K were excised from the membranes and directly subjected to N-terminal amino-acid sequence analysis using a gas-phase sequencer (Applied Biosystems, model 475-A) with an on-line microbore phenylthiohydantoin-amino-acid separator and data analyser (Applied Biosystems, models 120-A and 900-A). The N-terminal sequence of PN-II (ref. 3) and two PN-II peptide sequences were searched in the National Biomedical Research Foundation database using the Sequence Analysis Software Package of the Genetics Computer Group (University of Wisconsin) running on a VAX-VMS computer[25].

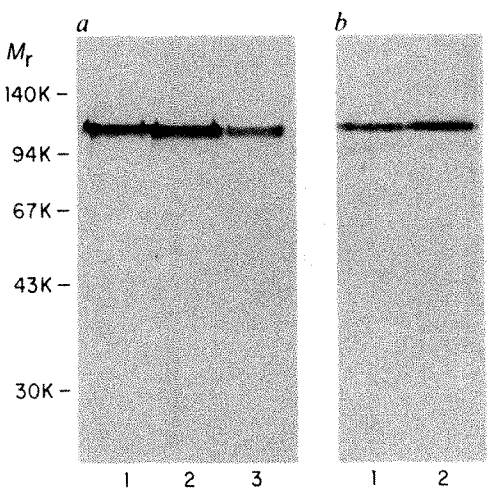

FIG. 2 Immunoblot analysis of PN-II in cell-culture media and brain-tissue homogenates. *a*, Monoclonal antibody mAbP2-1 stained identical proteins in PN-II-enriched culture medium from normal human fibroblasts (lane 1), human glioblastoma cells (lane 2) and human neuroblastoma cells (lane 3). *b*, This same monoclonal antibody stained apparently identical proteins in tissue homogenates from normal (lane 1) and Alzheimer's disease (lane 2) brain.

METHODS. The PN-II-specific monoclonal antibody, mAbp2-1, was prepared by fusing P3X63-Ag8.653 myeloma cells with splenocytes from a BALB/c mouse previously immunized with highly purified PN-II. The immunizations, fusion and subcloning were carried out as previously described for the preparation of PN-I-specific monoclonal antibodies[26]. Enzyme-linked immunosorbent assay (ELISA) demonstrated that mAbp2-1 specifically bound PN-II. The immunoblots show that mAbp2-1 recognized only PN-II in brain-tissue homogenates and cell-culture media. Fibroblasts from normal human neonatal foreskin, human glioblastoma HTB-14 cells and human neuroblastoma HTB-11 cells were cultured in DMEM medium containing 10% fetal bovine serum and antibiotics. Serum-free medium from the cultured cells was concentrated and enriched for PN-II by passing 100 ml of medium through a 1-ml DEAE-Sepharose column; the adsorbed protein was eluted with 2 ml of 1 M NaCl. Human-brain parietal cortex sections were placed in a buffer (20 ml per gram of tissue) containing 200 mM NaCl, 20% glycerol, 1% Triton X-100 and 20 mM potassium phosphate, pH 7.4, homogenized for 5 min using a Polytron homogenizer and centrifuged at 10,000*g* for 15 min at 4 °C to remove particulates. For immunoblots, samples were subjected to SDS-PAGE; completed gels were soaked in transfer buffer and the proteins were electro-eluted onto Immobilon polyvinylidene difluoride membranes for 2.5 h at 0.4 A in a Transblot unit. The membranes were gently agitated overnight at 25 °C in TBS (50 mM Tris-HCl, 150 mM NaCl, pH 7.5) containing 0.25% gelatin to block unoccupied sites, and then incubated with mouse monoclonal mAbP2-1 hybridoma-culture supernatant for 1 h at 37 °C with gentle agitation. After several washes with TBS containing 0.05% Tween-20, bound mouse mAbP2-1 was detected with a biotinylated sheep anti-mouse IgG (Amersham) and a streptavidin–horseradish peroxidase complex with several washes between each step. To develop the immunoblots, 48 mg of 4-chloronapthol were dissolved in 16 ml ice-cold methanol, and this was added to 80 ml ice-cold TBS and then to 64 μl H_2O_2.

^{125}I-labelled chymotrypsin bound to PN-II after SDS-PAGE of brain-tissue homogenates and cell-culture media from fibroblasts, neuroblastoma cells and glioblastoma cells (Fig. 4*c*). To further examine the inhibition of chymotrypsin by PN-II, the inhibition constant K_i was measured for the reaction. These studies showed that PN-II was a potent and reversible inhibitor of chymotrypsin with a K_i of 6×10^{-10} M. Reversible inhibition is characteristic of the Kunitz-type serine protease inhibitors[21], which are homologous to a domain in certain forms of APP[5,11,12]. Note that incubation of PN-II with chymotrypsin also resulted in proteolytically processed forms of the inhibitor which still retained their ability to bind and inhibit chymotrypsin (data not shown). Similar results have been reported for another Kunitz-type inhibitor, plasma inter-α-trypsin inhibitor[22].

Several findings have implicated the involvement of a chymotrypsin-like protease in the deposition of amyloid β-protein in Alzheimer's disease neuritic plaques. A methionine residue flanks the N-terminal side of the peptide bond that is cleaved on release of the amyloid β-protein from APP[4,5]. This site may be susceptible to cleavage by a chymotrypsin-like protease. It is noteworthy that the serpin α_1-antichymotrypsin is a component of the amyloid deposists in Alzheimer's disease and its expression is enhanced in Alzheimer's disease brain[10]. Here we have presented evidence indicating that the protease inhibitor PN-II is APP and that it effectively inactivates chymotrypsin.

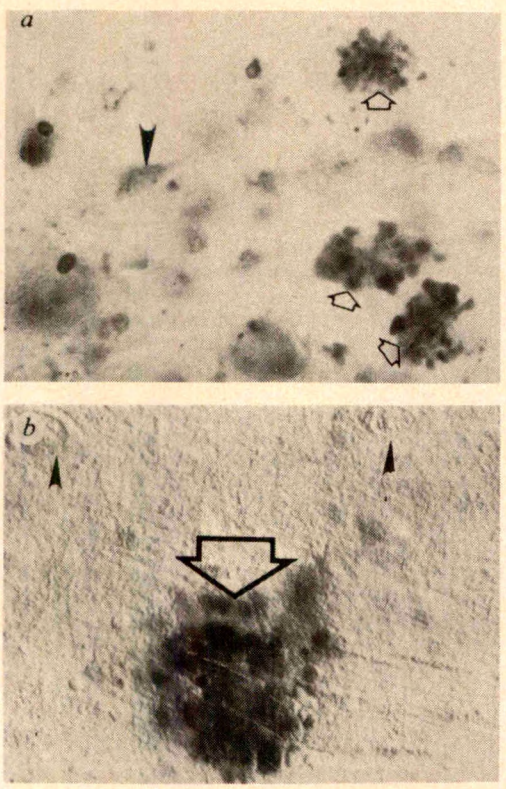

FIG. 3 Immunostaining of Alzheimer's disease neuritic plaques with monoclonal antibody mAbP2-1. *a*, Photomicrograph showing strong immunoperoxidase reaction for PN-II in scattered neuritic plaques (open arrows) in the CA1 region of the hippocampus of a 62-year-old female patient with Alzheimer's disease. Solid arrow points to a pyramidal neuron. Vibratome section (40 μm) viewed by brightfield microscopy (×200 magnification). *b*, Photomicrograph of a neuritic plaque on higher magnification showing strong immunoperoxidase reaction for PN-II (open arrow) in the CA1 region of the hippocampus. Solid arrows point to pyramidal neurons. Vibratome section (40 μm) viewed by Nomarsky interference microscopy (×1,000 magnification).

METHODS. Tissues were fixed overnight in 2% paraformaldehyde and 0.01% glutaraldehyde. After washing in PBS, vibratone sections were prepared and subsequently processed using an avidin-biotin complex, immunoperoxidase detection system for PN-II.

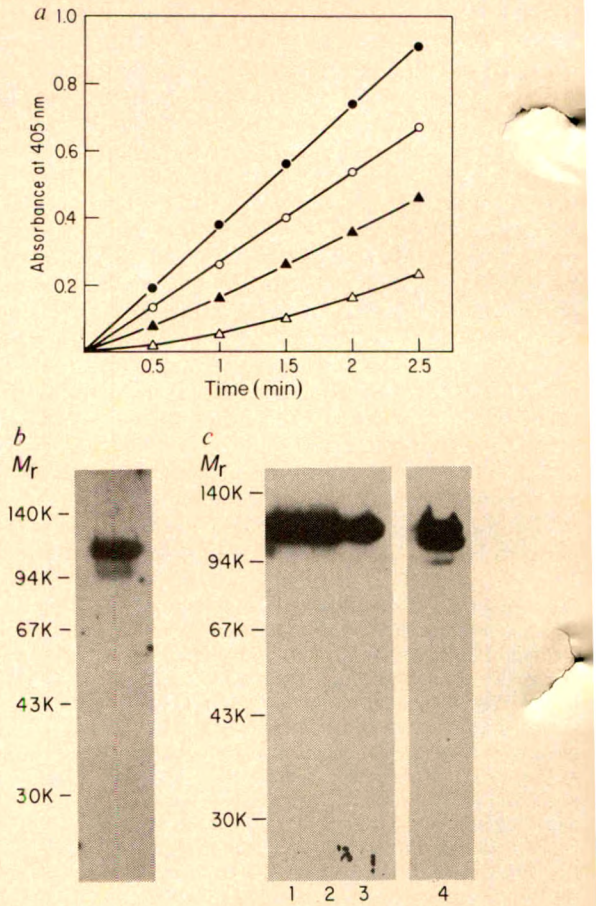

FIG. 4 Inhibition and binding of chymotrypsin by PN-II. *a*, Inhibition of chymotrypsin by PN-II. The molar ratios of PN-II to chymotrypsin were 0:1 (●); 0.5:1 (○); 1:1 (▲); and 2:1 (△). *b*, Binding of ^{125}I-labelled chymotrypsin to purified PN-II after subjecting the PN-II to SDS-PAGE and transferring to a nitrocellulose membrane. *c*, Binding of ^{125}I-labelled chymotrypsin to PN-II in medium of cultures of normal human neonatal foreskin fibroblasts (lane 1), human glioblastoma cells (lane 2), human neuroblastoma cells (lane 3), or in human brain-tissue homogenate (lane 4).

METHODS. K_i was determined by the method of Henderson[27] as simplified by Bieth[28] and recently described by Pratt and Pizzo[22]. In brief, increasing amounts of titrated PN-II were incubated with 20 nM active-site titrated chymotrypsin in 50 mM Tris-HCl, 150 mM NaCl, pH 7.5 containing 0.1% bovine serum albumin. Incubations were at 37 °C for 0.5–5 min. Remaining protease activity was measured by the addition of buffer containing the chymotrypsin-specific chromogenic substrate succinyl-Ala-Ala-Pro-Phe-*p*-nitroanilide (Sigma). Remaining chymotrypsin activity was monitored at an absorbance of 405 nm. Graphical analysis yielded an apparent K_i, $K_{i,app}$, using the equation $[I]/(1-a) = K_{i,app}(1/a) + [P]$, where [I] and [P] are the initial concentrations of inhibitor and protease, respectively, and *a* is the remaining fractional protease activity. Because the inhibition is reversible, a correction must be made for the Michaelis constant K_m of the protease–substrate reaction. The K_m for chymotrypsin and substrate was determined independently, and the true K_i was calculated using the equation

$$K_i = \frac{K_{i,app}}{1 + [S]/K_m}$$

Purified PN-II (2 μg) (*b*) or cell culture media or brain homogenates in which the PN-II had been partially purified and concentrated as described in Fig. 2 (*c*), were subjected to SDS–PAGE according to Laemmli[24]. The completed gel was soaked for 10 min in a transfer buffer consisting of 10 mM sodium bicarbonate, 3 mM sodium carbonate, 20% methanol, pH 9.9, and the PN-II was electro-eluted onto a nitrocellulose membrane for 2 h at 400 mA in Transblot unit (BioRad). After transfer, the nitrocellulose membrane was gently agitated overnight in a solution of TBS containing 0.25% gelatin to block unoccupied sites on the membrane, and then incubated with a solution of TBS containing 20 ng ml^{-1} of ^{125}I-labelled chymotrypsin (specific activity, 5.5×10^5 c.p.m. p mol^{-1}) for 20 min at 25 °C and then washed twice, each for 10 min, with TBS containing 0.05% Tween-20 and finally washed in TBS. Membranes were dried and exposed to X-ray film for 12–24 h at −70 °C.

There is a report that Alzheimer's disease brain contains higher levels of mRNA for APP lacking the domain of the Kunitz-type protease inhibitor than does normal brain[23]. Together, these findings indicate that a physiological function for PN-II/APP is the regulation of a chymotrypsin-like protease. This protease could generate amyloid β-protein and possibly other peptides that contribute to the formation of neuritic plaques. Future studies will determine if neural cells bind, internalize and degrade PN-II–protease complexes as do fibroblasts[1-3]. Alterations in this process could lead to extracellular accumulation of these complexes or of fragments of them. □

Capping of surface receptors and concomitant cortical tension are generated by conventional myosin

Carmela Pasternak, James A. Spudich & Elliot L. Elson*

Department of Cell Biology, Stanford University School of Medicine, Stanford, California 94305, USA
*Department of Biological Chemistry, Washington University School of Medicine, St Louis, Missouri 63110, USA

WE have investigated the role of cytoskeletal contraction in the capping of surface proteins crosslinked by concanavalin A on mutant *Dictyostelium* cells lacking conventional myosin[1]. Measurements of cellular deformability to indicate the development of cortical tension[2] show that cells of the wild-type parental strain, AX4, stiffen early during capping and relax back towards the softer resting state as the process is completed. Mutant cells lacking myosin (*mhc*A$^-$) have a lower resting-state stiffness, and fail to stiffen and to cap crosslinked proteins on binding concanavalin A. Hence conventional myosin is essential both for capping and for the concomitant increase in cell stiffness. Furthermore, depletion of cellular ATP by azide causes a 'rigor' contraction in AX4 cells which makes them stiffen and become spherical. By contrast, the *mhc*A$^-$ cells fail to respond in these ways. These measurements of cortical tension in non-muscle cells can thus be directly correlated with the presence of conventional myosin, demonstrating that contractile tension generated by myosin can drive both a change of cell shape and the capping of crosslinked surface receptors.

TABLE 1 Measurements of cellular contractile stiffening

Cell	Condition	Stiffness (mdyne μm^{-1} ±s.d.(*N*)
AX4	Resting	0·41 ± 0·15 (42)
AX4	Con A (during capping)*	0.91 ± 0.36 (34)
AX4	Con A (capping completed)*	0.52 ± 0.25 (15)
*mhc*A$^-$	Resting	0.28 ± 0.10 (40)
*mhc*A$^-$	Con A†	0.35 ± 0.12 (30)
AX4	Azide‡	2.00 ± 0.60 (15)
*mhc*A$^-$	Azide‡	0.46 ± 0.18 (17)

N is the number of cells measured.
* Stiffness was determined during the first 15 min after con A addition (during capping), or after 30 min incubation with con A (capping completed).
† Cells were measured at times up to 45 min after con A addition.
‡ After 30 min incubation with sodium azide.

Cellular stiffness was measured as described for lymphocytes[2]. *Dictyostelium* cells, grown and prepared as described in the legend to Fig. 1, were allowed to adhere to a glass coverslip for 1–2 min and then immersed in a 10 ml thermostated chamber mounted on the microscope stage. Measurements were made at 22 °C in oxygenated MES buffer, or in MES buffer containing 30 μg ml^{-1} con A or 10 mM sodium azide. The cells were slightly indented to a depth of 0.5–0.8 μm by a glass stylus of 1.5 μm diameter, which moved at a speed of 2.6 μm s^{-1}. Stiffness was defined as the resistance force per unit indentation depth, in units of mdyne μm^{-1}. The ingoing curves recorded with the cell poker were linear, so the stiffness parameter is well defined. The standard deviation represents the variability of stiffness values in the cell population. The precision in measurements of one cell is ±0.02 mdyne μm^{-1}.

The role of the cytoskeleton, and specifically of myosin-dependent contractile forces, in the active redistribution of cell-membrane proteins has been a subject of debate[3-5]. Capping of membrane proteins that have been crosslinked by the tetravalent lectin concanavalin A (con A) has been studied extensively in lymphocytes[6-8] and *Dictyostelium*[9,10]. Not only do actin, myosin and other cytoskeletal proteins co-cap with the con A receptors[6,7,9] in both types of cell, but the binding of con A to *Dictyostelium* causes a 20-fold increase in the concentration of myosin and a 3-fold increase in actin associated with the Triton-insoluble cytoskeleton[9]. Myosin thick filaments have also been visualized in the *Dictyostelium* cell cortex[11]. Both immunofluorescence[6,7,9,11] and mechanical studies[2] indicate, but do not prove, that a myosin-dependent cytoskeletal contraction drives capping. A more direct test is provided by eliminating myosin, the cytoskeletal protein that generates contractile force. This has now been accomplished in *Dictyostelium* by eliminating through homologous recombination the single gene coding for the heavy chain of conventional myosin[1]. The myosin null mutants (*mhc*A$^-$) in suspension are defective in cytokinesis, but on a substratum can fragment by a traction-mediated cytoplasmic fission (J.A.S. and S. J. Kron, unpublished results) and reach normal cell size[1]. The *mhc*A$^-$ cells may have subtle abnormalities in their motion and chemotaxis, similar to those characterized[12,13] in *Dictyostelium hmm* cells[12], which express only the head fragment of myosin. To determine whether a myosin-dependent contractile process is responsible for cellular stiffening and capping of con A receptors in *Dictyostelium*, we have directly measured changes in these parameters in AX4 wild-type *Dictyostelium* cells and in *mhc*A$^-$ myosin null mutants.

The response of AX4 cells to con A is similar to that of lymphocytes[2]. About 50% of the AX4 cells cap fluorescein-labelled con A receptors, with maximal capping occurring 7–10 minutes after addition of con A at 22 °C (Fig. 1*a*). By contrast, the *mhc*A$^-$ myosin null cells fail to cap con A-labelled surface proteins (Fig. 1*b*). No capping is detected in these cells even after 90 minutes of incubation with con A (data not shown).

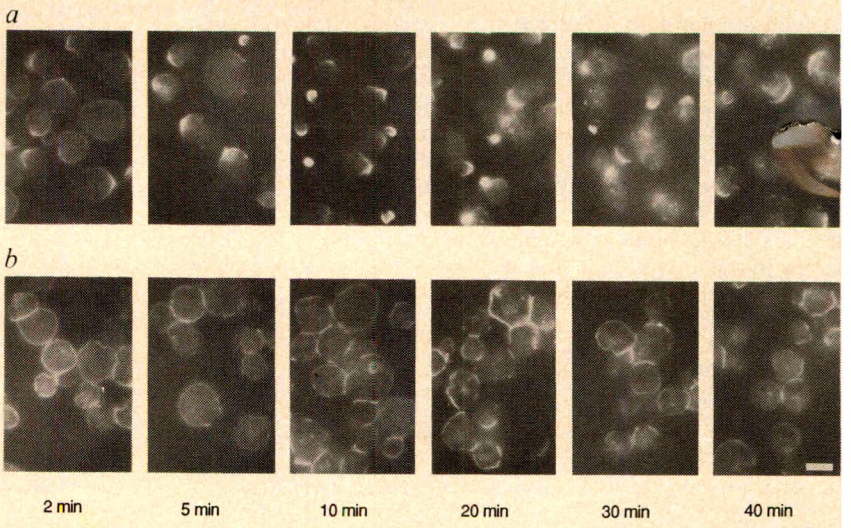

FIG. 1 Redistribution of crosslinked con A receptors into a cap depends on the presence of myosin in the cells. Cells were labelled with fluorescein isothiocyanate-labelled con A (FITC-conA). *a*, Time-dependence of con A-capping in AX4 *Dictyostelium* cells. Maximal capping occurred about 10 min after addition of con A and ~50% of the cells capped. At later times most of the ligand was internalized. *b*, Mutant *mhc*A$^-$ cells that lack myosin fail to redistribute con A receptors into a cap. The crosslinked surface receptors can cluster and accumulate in contact regions between cells, indicating that the con A receptors are mobile in the membrane of the mutant cells. These cells internalize some of the labelled con A. Scale bar, 10 μm.

METHODS. The axenic strain of *Dictyostelium*, AX4, and *mhc*A$^-$/A5 *Dictyostelium* myosin null mutant cells were grown in tissue culture plates (Falcon) in HL5 defined medium. The medium for *mhc*A$^-$ cells contained 6 μg ml^{-1} G-418 (ref. 1). The cells were removed by flushing the medium gently with a pipette and then washed in oxygenated MES buffer (20 mM (2[*N*-morpholino]ethanesulphonic acid), 2 mM $MgSO_4$, 0.2 mM $CaCl_2$, pH 6.8; oxygen was bubbled through the buffer for 20 min). Cells were collected by centrifugation at 2,000 r.p.m. for 2 min. For fluorescence microscopy, cells were treated with 30 μg ml^{-1} FITC-Con A (Sigma) and swirled in an open beaker. Two minutes before fixation with paraformaldehyde the cells were allowed to adhere to glass coverslips pretreated with 0.1 mg ml^{-1} poly-L-lysine (Sigma) for 15 min and washed in MES buffer. Cells were fixed in 2% paraformaldehyde in MES buffer for 15 min at the times indicated. Coverslips were washed with MES buffer, inverted onto glass slides in the presence of 50% glycerol, 50% MES and then sealed using clear nail polish. Cells were visualized and photographed using a Zeiss M-35 microscope with a 100 × oil immersion objective and attached camera.

Some internalization of con A-labelled proteins seems to occur in *mhc*A$^-$ cells. In experiments complementary to those we describe here (Y. Fukui, A. De Lozanne and J.A.S., submitted), *hmm* cells fail to cap con A, indicating that the tail portion of the myosin, which is involved in thick-filament formation, is essential for the capping process.

Using a direct method to measure cortical tension, we find that AX4 cells stiffen in response to con A, as previously shown for lymphocytes[2]. An increased stiffness of AX4 cells was detectable, starting about two minutes after addition of 30 μg ml^{-1} con A. The stiffness increased to 0·90 mdyn μm^{-1}, which is substantially greater than the 0.41 mdyn μm^{-1} value in the resting condition. Following capping, from 30–45 minutes after addition of con A, the average stiffness decreased to 0.52 mdyn μm^{-1} (Table 1). As shown previously for lymphocytes[2], the time-dependence of the mechanical response correlates with the capping of surface receptors.

The myosin null cells have a lower resting stiffness, 0.28 mdyn μm^{-1} (Table 1), indicating that some of the stiffness of the resting cells results from myosin-dependent cortical tension. Also, in contrast to the AX4 wild-type cells, the stiffness of the mutant cells increases only slightly from 0.28 mdyn μm^{-1} to 0.35 mdyn μm^{-1} in response to con A (Table 1) and is not time-dependent. The failure of the mutant cells either to stiffen substantially or to cap indicates that a myosin-dependent contraction is involved in both processes.

These results are consistent with a model for capping in which crosslinking cell-surface proteins by con A activates a myosin-dependent cytoskeletal contraction. This contraction is possibly mediated by the same intracellular responses as in lymphocytes: activation of the phosphoinositide cascade[14], an increase in intracellular calcium[15], and phosphorylation of myosin light chains[16]. The resulting isometric tension in the cell cortex causes the increased stiffness. Release of the tension at one location in the cortex allows actin, myosin, other actin-associated proteins and the crosslinked surface proteins to be drawn, possibly by an isotonic contraction, to the opposite pole of the cell to form the cap. Our results demonstrate that *Dictyostelium* cells that lack conventional myosin cannot perform these functions.

To probe further the role of myosin in controlling cellular morphology and also to test the possibility of developing a 'rigor' contraction in non-muscle cells, we treated *Dictyostelium* cells with 10 mM NaN_3 for 30 minutes to deplete cellular ATP. This concentration and incubation period has been shown to reduce the cellular ATP concentration to ~5% of its original level in hepatocytes[17]. The AX4 cells respond to azide by immediately retracting spread regions to assume a smooth-surfaced spherical shape (compare Fig. 2*a* and *c*) and their stiffness increases 5-fold from 0.41 mdyn μm^{-1} to 2.0 mdyn μm^{-1} (Table 1). In contrast, the *mhc*A$^-$ cells show no detectable morphological response to azide (Fig. 2*b* and *d*) and a relatively small increase in stiffness from 0.28 to

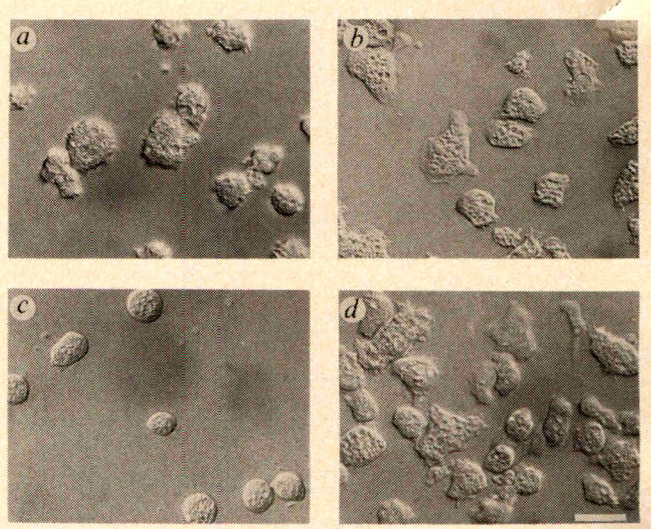

FIG. 2 Azide causes a 'rigor' contraction in *Dictyostelium* cells that have conventional myosin, but does not affect the morphology of myosin null mutants. *a*, *Dictyostelium* AX4 cells in MES buffer; *b*, *mhc*A$^-$ *Dictyostelium* cells in MES buffer. These cells tend to spread more and internal vacuoles are more visible. *c*, AX4 cells after 30 min incubation with 10 mM sodium azide. The cells round up and contract and the surface becomes smooth. They tend to detach from the coverslip. *d*, Morphology of *mhc*A$^-$ cells and their adhesive properties are not affected by incubation with azide. Scale bar, 20 μm.

METHODS. AX4 and *mhc*A$^-$ cells in MES oxygenated buffer were allowed to adhere to round glass coverslips for 5 min and then inverted onto glass slides holding a drop of MES buffer or MES buffer with 10 mM NaN_3. After 15 min the coverslips were sealed using warm wax and a thin circle of filter paper around the circumference of the coverslip. Cells were visualized using a Zeiss IM-35 microscope with a 40 × objective, and photographed after 30 min incubation with MES buffer or MES buffer containing 10 mM azide.

0.46 mdyn μm^{-1} (Table 1). This small change could result from osmotic effects caused by inhibition of ion pumps, or from other types of myosin[18], or possibly from other ATP-dependent systems. The effect of azide on the wild-type AX4 cells indicates that, as in skeletal muscle[19], ATP depletion can cause a rigor contraction in *Dictyostelium*. Azide has also been shown to prevent capping of crosslinked surface receptors[6,10], presumably by inducing a rigor contraction which fixes the cells in a non-motile state.

Determination of the cellular functions of cytoskeletal proteins has proved difficult because, unlike enzymes, which have readily measurable catalytic activity, cytoskeletal proteins have structural and mechanical functions that are more difficult to measure. Elimination of a specific protein from a cell, either functionally[20–22] or genetically[1,23], has been used to assess qualitative effects on cell morphology or motility, but direct quantitative assay of mechanical function, such as we report for conventional myosin in single non-muscle cells, is a more discriminating test. Although conventional myosin is not required for morphological changes such as lamellar extension during locomotion[13], it clearly can influence cell shape (Fig. 2), as well as drive a contractile process that moves surface receptors into a cap. Our measurements have demonstrated that capping in *Dictyostelium* is associated with a cellular stiffening and that both capping and stiffening fail to occur in cells lacking conventional myosin. These results support the hypothesis[2,3,7,9] that stiffening results from an actin–myosin contraction and that this contractile force is responsible for capping. For example, release of tension at one location would allow crosslinked membrane proteins and associated cytoskeletal components to be drawn together to form a cap at the opposite pole of the cell. Because of similarities in capping in *Dictyostelium* and lymphocytes, it is likely that this mechanism also operates in capping of lymphocyte surface receptors. □

THE introduction of foreign mitochondria or mitochondrial DNA into a cell is a useful technique for clarifying the molecular mechanisms responsible for the maintenance of mitochondria. Novel combinations of mitochondrial and nuclear genomes have been studied in mammalian cells in culture[1–6] and in yeast[7,8,14,15]. In *Drosophila*, we have recently constructed heteroplasmic flies possessing both endogenous mitochondrial DNA and foreign mitochondrial DNA by intra- and interspecific transplantation of germ plasm[9]. During the maintenance of these heteroplasmic lines, flies of *D. melanogaster* are produced that no longer possess their own mitochondrial DNA but retain the foreign mitochondrial DNA from *D. mauritiana*. These flies are fertile and the foreign mitochondrial DNA is stably maintained in their offspring. Here we report the complete replacement of endogenous mitochondrial DNA with that from another multicellular species. Molecular and genetic analysis of this replacement in *Drosophila* should provide new insight into the functional interaction between nuclear and organelle genomes.

D. melanogaster and *D. mauritiana* belong to the *melanogaster* species subgroup in *Drosophila*. An interspecific combination of nuclear and mitochondrial genomes cannot be established by crossing, owing to the sterility of the interspecific hybrids[10]. Germ plasm rich in mitochondria[11] was transplanted into freshly laid eggs[9] using *bw*;e^{11} (brown eye and ebony body colour) of *D. melanogaster* as a recipient, and *D. mauritiana* (g20 strain) as a germ-plasm donor. Mitochondrial DNAs (mtDNAs) of *bw*;e^{11} and g20 can be readily distinguished by their *Hae*III restriction enzyme digest patterns (Fig. 1*a*).

Four heteroplasmic lines (C5, D2, D3 and F3), established from individual heteroplasmic females[9] and possessing both recipient (*bw*;e^{11})- and donor(g20)-derived mtDNA (Fig. 1*a*), were maintained at 25 °C. The proportion of donor mtDNA in progeny flies was monitored in subsequent generations. During

† To whom correspondence should be addressed.

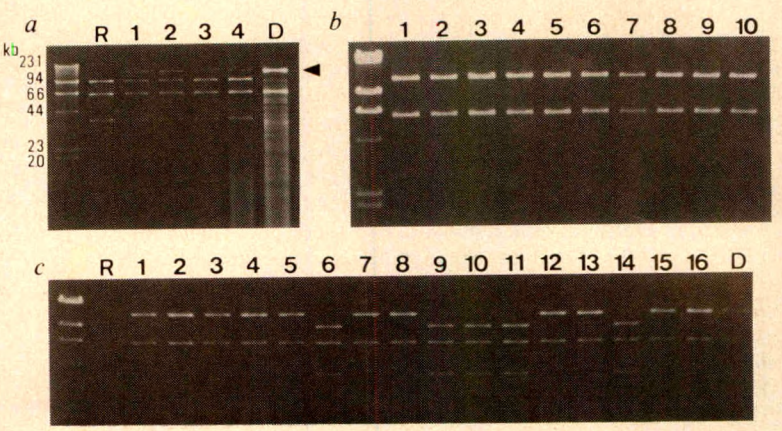

FIG. 1 Examples of *Hae*III restriction patterns of mtDNA from heteroplasmic lines and sublines. Mitochondrial DNA was extracted from adult flies, digested and separated on 0.8% agarose gels[9,12]. In the first lane of each gel, fragments from lambda phage DNA digested with *Hin*dIII are shown as size markers; *bw*;e^{11} (recipient, *R*) mtDNA and g20 (donor, *D*) mtDNA are run next to the size marker lane and in the last lane, respectively, in *a* and *c*. *a*, Mitochondrial DNA from the four heteroplasmic lines: C5 (lane 1), D2 (lane 2), D3 (lane 3) and F3 (lane 4), at the second generation. The diagnostic band for g20 mtDNA is indicated by an arrowhead. *b*, Mitochondrial DNA from sublines established from the D2 line at the 15th generation (lanes 1–10). *c*, Mitochondrial DNA from sublines established from the C5 (lanes 1–7) and F3 (lanes 8–16) lines at the 32nd generation.

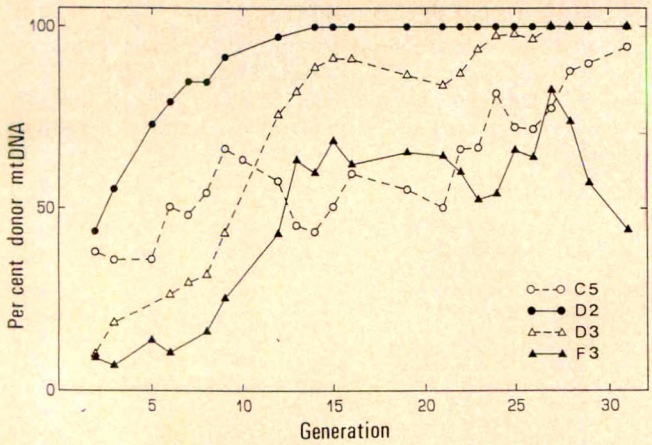

FIG. 2 Change in the proportion of g20 mtDNA in four heteroplasmic lines. These lines were maintained at 25 °C by brother–sister mating of 50–100 flies in each generation. Mitochondrial DNA was extracted from flies used as parents for the next generation and the proportion of g20 mtDNA was determined[9].

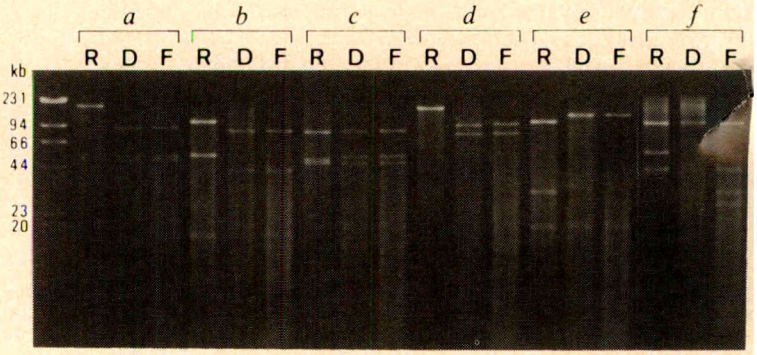

FIG. 3 Restriction patterns of *bw*;e^{11} (recipient, *R*), g20 (donor, *D*) and D2 (fixed, *F*) mtDNA. These patterns are consistent with the restriction maps of mtDNA reported by Solignac *et al.*[13]. *a*, *Bgl*II; *b*, *Eco*RI; *c*, *Hin*dIII; *d*, *Hpa*I; *e*, *Pvu*II; *f*, *Sac*I.

the first ten generations, the proportion of g20 mtDNA gradually increased in all four lines (Fig. 2). Finally, *bw*;e^{11} mtDNA ceased to be detectable in the D2 and D3 lines after 14 and 27 generations, respectively. To date, we find that recipient mtDNA has been absent for more than 25 generations. The interspecific combination of nuclear and mitochondrial genomes apparently does not hinder the survival of a host fly, at least under these conditions.

To determine whether recipient mitochondria are lost in each female, ten sublines were established from individual females inseminated by their brothers in the D2 line at the 15th generation, and the progeny mtDNA was digested with *Hae*III. All ten sublines showed the restriction pattern of g20 mtDNA and none showed the mtDNA band characteristic of *bw*;e^{11} (Fig. 1*b*). We conclude that the mtDNA of *bw*;e^{11} (*D. melanogaster*) has been completely replaced by mtDNA of g20 (*D. mauritiana*) in each female in the D2 line.

Replacement of *bw*;e^{11} mtDNA and fixation of g20 mtDNA was confirmed using another six restriction enzymes: *Bgl*II, *Eco*RI, *Hin*dIII, *Hpa*I, *Pvu*II and *Sac*I. These enzymes gave restriction patterns for mtDNA of the D2 line that were the same as those from the original g20 strain, but differed from those derived from *bw*;e^{11} mtDNA (Fig. 3). We further verified fixation of g20 mtDNA by Southern hybridization, using a ^{32}P-labelled mtDNA fragment of *D. melanogaster* as a probe: this probe hybridized to each of the bands diagnostic for *bw*;e^{11} and g20 mtDNA (data not shown). It is therefore evident that mtDNA of the D2 line originates from the donor (g20) mitochondria and is not derived from a change in *bw*;e^{11} mtDNA by mutation, recombination or fusion with g20 mtDNA.

In the C5 and F3 lines, two types of mtDNA co-exist among the progeny even at the 32nd generation. To determine whether this results from a heteroplasmic state in individual flies or from the co-existence of flies each carrying one type of mtDNA, we examined the *Hae*III restriction pattern of mtDNA from the progeny of the 14 and 16 sublines of C5 and F3, respectively. All these sublines were found to carry only one type of mtDNA: either *bw*;e^{11} in 2/14 of C5 and in 7/16 of F3, or g20 in 12/14 of C5 and in 9/16 of F3 (Fig. 1*c*). Fixation of foreign mtDNA in each female therefore also occurs frequently in these two lines.

D. mauritiana mtDNA can be retained in the absence of its own nuclear genome, although in cultured mammalian cells, mitochondria may depend on the presence of species-specific nuclear gene products for their own survival[1–3]. We marked the second and third chromosomes of *D. melanogaster* with recessive genetic markers of *bw* and e^{11}, respectively. All flies emerged with the *bw*;e^{11} phenotype and so there could have been no contamination by *D. mauritiana* nuclei during the transplantation of germ plasm.

Fixation from the heteroplasmic state was significantly biased towards a preference for donor mtDNA among the individuals in the four lines. Although the reason for this is not yet clear, *D. mauritiana* mtDNA is apparently distinguishable from *D. melanogaster* mtDNA, in spite of the extensive homology between their mitochondrial genomes[12]. In cultured somatic cells, cells with only one type of mtDNA have been selected from heteroplasmic cells using medium containing chloramphenicol, for example[2–6]. It is significant that we have found preferential fixation of foreign mtDNA in the absence of selective conditions.

It remains to clarify the mechanisms by which the propagation of *D. mauritiana* mtDNA and of chimaeric mitochondria encoded by both *D. mauritiana* mtDNA and *D. melanogaster* nuclear DNA, are regulated under the nuclear genome of *D. melanogaster*. Experiments are in progress on reciprocal combination and on other intra- or interspecific combinations between nuclear and mitochondrial genomes, which aim to clarify the factors involved in regulating the maintenance of mtDNA and mitochondria. □

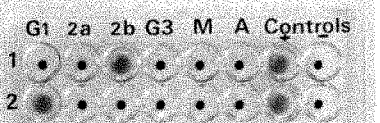
THE NEW SEROTEC MOUSE MONOCLONAL ISOTYPING KIT



Once again Serotec add to the range of affordable excellence

Why waste time with lengthy ELISA and IMMUNODIFFUSION procedures? With the NEW Serotec Mouse Monoclonal Isotyping Kit you can have conclusive results to the class/subclass of your monoclonal antibody in ONLY 1 HOUR (and there are no inconvenient washes or incubations).
The kit is ideal for • characterising class/subclass of monoclonal antibodies • detecting mixed clones • isolating class-switch variants • monitoring clones for loss of ability to secrete antibody • screening for specific isotypes during cloning and selection of novel antibodies.

To place an order or to obtain more information contact:

Note – Kits for rat and human subclasses to follow soon!

Peptide and Amino Acid Transport Mechanisms in the Central Nervous System

Edited by L Rakic, Professor of Neurobiology and Biochemistry, Belgrade Clinical Centre; David J Begley, Lecturer, Department of Physiology, King's College London; Hugh Davson, Professor of Physiology, St Thomas Hospital, London and Berislav, Associate Professor, Belgrade University Institute of Medical Physiology

The way in which the brain regulates its internal environment separately and distinctly from the rest of the body has long generated intense interest and debate. Today, advances are being made at an ever accelerating rate. This volume addresses itself to regulation, within the brain extracelluar fluid, of peptide and amino acid levels, particulary those which are known or putative neurotransmitters and neuromodulators. Particular attention is also devoted to the way in which peptides may penetrate the blood-brain barrier or alter its permeability to other solutes. This volume is of vital relevance to anyone studying central nervous system disease, especially the fundamental problem of designing drugs and agents which will penetrate the blood-brain barrier and excert central nervous actions. The relevance to mental health and disease is also unquestioned.

Peripheral Actions of Dopamine

Edited By Christopher Bell, Department of Physiology, University of Melbourne, Australia and Barry McGrath, Monash University Medical School, Melbourne, Australia

This book reviews the current state of research in three main areas concernng the actions and significance of dopamine in the periphery: the source and effects of endogenous dopamine; the classification and distribution of, and the effects of activating, various populations of peripheral dopamine; and the therapeutic significance of dopamine receptor activation and renal disease.

Contents: Sources of Circulating Dopamine: A Personal View: J-L. Cuche / Dopamine Storage in Sympathetic Nerves: P. Soares-Da Silva / Neurochemistry of Dopaminergic Nerves: C. Bell, M. Ferguson & T. Petrovic / Release of Dopamine from the Kidney in vivo: P. Hjemdahl, T. Bradley & B. Tidgren / Dopamine and Renal Failure: W. Adam / Dopamine and Hypertension: M. Yoshimura & H. Takahashi / The Vascular (DA1) Dopamine Receptor: J.D. Kohli & L.I. Goldberg / Renal Dopamine Receptors: R.A. Felder, C.C. Felder, G.M. Eisner & P.A. Jose / Gastrointestinal Dopamine Receptors: R.A. Lefebvre / Neuronal Dopomine Receptors: M.F. Lokhandwala & M.L. Defeo / Drug Design for Cardiovascular Therapeutics: Activation of DA1 Receptors: B.A. Berkowitz / Use of Dopamine Agonists in Cardivascular Disease: B.P. McGrath, N. Sano & B.F. Jover / Modified Dopamine Agonists: R.D. Hoskins, R.A. Brown, R.A. Foulds, F. Ince, S. O'Connor & G.W. Smith / Dopamine Pro-Drugs: M.R. Lee / Index

New Concepts in Depression

Pierre Fabre Monograph Series, Volume 2

Edited by M. Briley, Pierre Fabre Medicament, Castres, France and G. Fillion, Head of Neuroimmunoendocrinology, Pasteur Institute, Paris

Depression is increasingly seen as an important debilitating neurological condition. This book brings together a timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression. In addition, a number of chapters concentrate on clinical or physiological phenomena associated with depression. The general attitude of the book is one of openness to new ideas several of which are presented here for the first time.

Contents: The Contributors / Preface to the Series / Preface / Biochemical Mechanisms in Depression / 5-HT and Depression / Physiological Correlates in Depression / From Experimental Models to Man / Clinical Pharmacology of Depression and Associated Phenomena

Cost Versus Benefit in Cancer Care

Edited by Basil Stoll, Honorary Consultant, St Thomas' Hospital, London

In view of spiralling health costs in Western countries, physicians on both sides of the Atlantic must reach agreement on what is 'appropriate' treatment for patients with advanced cancer. This book is the first to expose the dilemma between cost and benefit in the treatment of advanced cancer. It is written for physicians, who ultimately have to make the choices in allocating resources, and discusses frankly the reasons for differences in treatment across the Atlantic.

Contents: Introduction: G. Mooney PART 1 CURRENT DILEMMAS What is Overtreatment in Cancer? B.A. Stoll What is Best for the Patient? United States View A.U. Buzdan What is Best for the Patient? European View G.J.G. Rees The Patient's Expectations in the United States A.S. Brett The Physician's Attitude in Britain D. Radstone Focus on Clinical Trials: E.A. Eisenhauer & W.J. Clinical Cancer Monographs

Clinical Cancer Monographs is a new series presenting the data compiled by the English West Midlands Regional Cancer Registry, by site of malignancy. The unique feature of the series is the presentation and analysis of data not just on incidence, but also on treatments and the effect of treatments on survival. The records used in the analysis cover a 25 year period and a population of 5 million people, with demographic characteristics which serve as a useful model for other regions in industrialized countries. The series will be of great value to oncologists and clinicians as well as health planners and medical statisticians.

WOLFSON RESEARCH PROFESSORSHIP

The Wolfson Research Professorship, held by Professor Dorothy M.C. Hodgkin, O.M., from 1960 to 1977 and by Professor A.R. Fersht from 1978 to 1989, is now vacant and applications are invited by the Council of the Royal Society for appointment from 1 October 1990 or thereafter. The professorship will be for research in physics or chemistry at their interfaces with biology.

The appointment will be subject to the Society's General Regulations governing Royal Society Research Professorships. Candidates must be British citizens or citizens of independent Commonwealth countries and must hold the appointment in a university or other research institution in the United Kingdom.

Salary and conditions of tenure

The salary will be on the prevailing professorial minimum for professors in United Kingdom universities plus one-third (making a current total of £33 044 p.a. with London Allowance £1650 p.a. where appropriate) and tenure is for five years in the first instance, renewable thereafter until age 65. Superannuation benefits will be provided and there is provision for research expenses (currently £13 500 p.a.), support of a research assistant or technician and start-up expenses (up to £35 000).

Method of application

Intending applicants should write for further details, which will be issued up to 4 December 1989, (there is no application form) to:

Mrs U.M.A. Tokle, The Royal Society,
6 Carlton House Terrace, London, SW1Y 5AG.

Closing date: 15 December 1989. No applications arriving after 4 p.m. on 15 December will be considered.

UNIVERSITÄT TÜBINGEN

Im Rahmen der neurobiologischen Programme der Universität Tübingen wird die Hörforschung verstärkt. Das Laboratorium für Hörforschung der Univ.-Hals-Nasen-Ohren-Klinik bietet Stellen für wissenschaftliche Mitarbeiter (BAT II/I) in einer Gruppe an, die sich mit Physiologie und Pathophysiologie des auditorischen Transduktionsprozesses sowie technischen Hilfen für Hörgeschädigte befaßt.

Wissenschaftliche/r Mitarbeiter/in Molekularbiologie, Neurobiologie

Das molekularbiologische Projekt umfaßt beispielsweise das Studium von Haarzellproteinen mittels cDNA-Techniken und soll sich auch mit der Identifizierung, Isolierung und Charakterisierung von Genen und Genprodukten befassen, die an der Entstehung von Schwerhörigkeiten beteiligt sind.

Wir suchen einen Forscher (Naturwissenschaftler oder Mediziner) mit Erfahrungen in der Molekularbiologie des Mammalier. Die Position erfordert den Doktorgrad mit etwa zwei-jahregim relevanten Postdoktorandentraining. Promovierte mit überdurchschnittlicher Promotion in der Molekularbiologie kommen auch ohne Postdoktorandenzeit in Frage. Entscheidend ist der Nachweis von Forschungseffizienz, welcher auf die zukünftige Fähigkeit von Drittmitteleinwerbungen schließen läßt.

Erfahrung in der Hörforschung ist nicht erforderlich. Erfolgreiche Bewerber werden in einem Team von Biologen, Physikern und Ärzten innerhalb des Laboratoriums für Hörforschung tätig sein. Die Entwicklung einer eigenständigen Arbeitsgruppe für Molekularbiologie ist vorgesehen.

Diplomingenieur/in Elektrotechnik/Akustik

Zur Forschung und Entwicklung von technischen Implantaten für Hörgeschädigte suchen wir einen einsatzfähigen, Diplomingenieur als Mitglied in einem Team von Biologen, Physikern und Ärzten. Das Arbeitsgebiet umfaßt transcutane Signallübertragung, mechanoelektrische und elektro-mechanische technische Transduktion, Mikrohydraulik, Energieträger sowie deren Biokompatibilität. Im Rahmen eines Verbundes zwischen Universität Tübingen und Universität Stuttgart sowie mittelständigen Industrieunternehmen ist eine Kooperation vorgesehen. Die Vergütung erfolgt nach BAT sowie einem leistungs-abhängigen Zuschlag, mit dem vergleichbare industrielle Ein-kommen erreicht werden. Entsprechende überdurchschnittliche Qualifikation und Einsatzbereitschaft wird erwatet.

(W6578)A

CHAIR

MOLECULAR AND HUMAN GENETICS
EMORY UNIVERSITY

The School of Medicine seeks a Professor and Chairperson for a new Department of Molecular and Human Genetics. Emory has an established genetics research group, and an interdepartmental Graduate Program in Genetics and Molecular Biology. The School of Medicine is now forming a new basic medical science department, with several additional positions and significant new laboratory space. Nominations or curriculum vitae will be considered until December 1, 1989 or until the position is filled. Please submit them to: **Dr. Robert B. Gunn, Chairman of Search Committee, 302 WHSCAB, Emory University School of Medicine, Atlanta, GA 30322.** *Emory University is an equal opportunity employer.*

(NW4373)A

The newly formed Basic Science Department of Microbiology at the University of Texas Medical School, at Houston, invites applications for both tenure track and tenured faculty positions at the level of

Assistant, Associated or Full Professor.

The initial areas of recruitment interest are in: Procaryotic Microbial Physiology, Microbial Genetics and Molecular Microbiology. Candidates must have the Ph.D. and/or the M.D. degree. Postdoctoral Research experience is essential for consideration of a prospective assistant professor. Applicants for associate or full professorships must have demonstrated high quality research performance. Successful applicants will be expected to teach medical students, graduate students and develop and/or maintain a high level, high visibility research program, competitive at the national level. Please send a curriculum vitae and a statement of teaching and research interests as well as the names of four referees to: **Dr. Samuel Kaplan, Department of Microbiology, The University of Texas, Medical School, at Houston, P.O. Box 20708, Houston, Texas 77225.** *The University of Texas Health Science Center is an Equal Opportunity Employer. Woman and minorities are encouraged to apply.* (NW4384)A

Elsevier Science Publishers B.V. (ESP) is the science publishing company of the Elsevier group, with companies in Europe, U.S.A. and Japan. ESP publishes six hundred journals in the fields of science, engineering and biomedicine, as well as books and electronic products. The Phsysical Sciences and Engineering Division is seeking

chemists or chemical engineers m/f

to train as acquisition editors within our chemistry section.

You will be joining an experienced and highly motivated team involved in the management and development of publications for the international chemistry and chemical engineering markets.

Specifically, your responsibilities will include playing a part in the management of our substantial list of international journals, in the development of our book publishing programme, and in the initiation of publications using electronic media and other formats. You will also spend several weeks a year travelling in Europe, North America and elsewhere in order to make contacts with potential authors and editors.

The position of acquisition editor demands the talents of a self-motivated and outgoing individual with sound commercial sense who can contribute to the maintenance of the high scientific and editorial standards of our publishing programme. The succesful candidates will most likely be in their late twenties or early thirties and will probably have a Ph.D. or equivalent experience in one of the fields of chemistry or in chemical engineering. In addition to a formal academic training, the candidates will have had a further two or three years of working experience in a university, industrial or other environment. An excellent command of English will be essential.

The positions are based at our head office in Amsterdam (the Netherlands).

We offer a challenging career opportunity to those graduates who wish to develop in a commercial environment with a successful company in a competitive market

Starting salary from Dfl. 55 - 75.000,- with attractive benefits.

For further information contact Mrs. T. Sijpesteyn, publisher (0)20 - 586 2795.

Your application, mentioning nr. 401/03/NA can be sent - within 3 weeks - to ESP Personnel Department, P.O. Box 2400, 1000 CK Amsterdam, The Netherlands. Owing to Dutch labour regulations we can only consider applications from EEC-residents.

KAROLINSKA INSTITUTE

CBT
CENTER FOR BIOTECHNOLOGY

RESEARCH ASSISTANT/ POSTDOCTORAL RESEARCH ASSISTANT

Center for BioTechnology is a new and rapidly expanding unit within the Karolinska Institutet located at Huddinge University Hospital in Stockholm.

Applications are invited for a graduate/Post doctoral research assistant to join a group working on the characterisation of embryonic growth factors as well as aberrant growth factor expression in human embryonic tumours. The position is suitable for a person with an honours degree in science, and will involve the molecular cloning and subsequent characterisation of such factor(s).

The position is initially for one year, with the possibility of extension for another two years. Annual salary is in the range of 120–160.000 SEK.

Applications should be sent to **Dr Wilhelm Engström, Center for Biotechnology, Karolinska Institute, NOVUM, 141 86 Huddinge, Sweden** together with a c.v. and names of three referees. (W6606)A

St Bartholomew's Hospital
Departments of Histopathology and Virology

RESEARCH ASSISTANT

£9,855–£12,340 pa inc.

A vacancy exists from January 1st, 1990 for a Research Assistant with interests in medical virology and viral oncogenesis. The post is funded for 3 years for investigations into human herpes virus infections and employing molecular biological techniques, including filter and in situ hybridisation and the polymerase chain reaction. These methods will be used to investigate sites of viral latency, expression of viral transcripts during latency and reactivation, and expression of viral genes in various human malignancies.

Applicants should have experience in medical virology and/or molecular biology and have a degree in a biological science or an equivalent professional qualification. The appointment will be made on the PTA scale (£9,855–£12,340), according to qualifications and experience.

Informal enquiries can be made to Dr Phil Coates or Dr Hilar Kangro on 01–601 8888 ext 8298/7355 respectively.

Application forms and job description are available from the **Personnel Department, St Bartholomew's Hospital, West Smithfield, London EC1A 7BE.** Tel: 01–601 8590 quoting ref no D/125.

Job share applicants welcome.

Closing date. 2nd November 1989.

The City & Hackney Health Authority. Working Towards Equal Opportunities (1842)A

CARDIOVASCULAR SCIENTIST

A cardiovascular physiologist/pharmacologist is required to provide scientific leadership to a team of 4-6 research scientists and technicians engaged in the discovery and development of novel agents for the treatment of ischaemic heart disease and related disorders The appointed person will possess, an in-depth background knowledge of the assessment of haemodynamic and/or electrophysiological measurements in chronic or acute models of cardiovascular disease states, together with a Ph D and some postdoctoral experience either within the pharmaceutical industry or at an academic centre of excellence A knowledge of the French language is desirable

SANOFI is a major Pharmaceutical Company involved in Research and Development in pharmaceutical, veterinary and agricultural activities It has major research centers in many parts of Europe including Brussels, Milan, Montpellier, Toulouse and Paris

The Research Center of SANOFI-LABAZ is situated on the outskirts of Brussels in an attractive part of Europe and offers superbly equipped new laboratories This position offers a comprehensive salary and benefits package

Please write enclosing a full curriculum vitae to

Where molecular modelling counts

British Bio-technology is a research and development company in health sciences. Utilising both molecular biology and medicinal chemistry techniques, the company aims to bring innovative pharmaceutical products to the human health care market in the 1990's and beyond.

SENIOR DRUG DESIGN SCIENTIST

COMPUTATIONAL CHEMISTRY AND MOLECULAR MODELLING

Computer systems are used extensively by our Medicinal and Protein Chemists in the design of drug molecules and engineered proteins. This current vacancy is for a chemist or biochemist with a PhD and several years' experience using computer systems in drug design. The post will head up the drug design section within our computing department. It carries responsibility for keeping the company at the leading edge of applications of computers for drug design and in training and assisting our scientists in using these systems in a number of our research projects.

The company uses both CHEM-X and Polygen software, has a network of VAX computers, a Mitie transputer system, Silicon Graphics 4D/70GT workstation and an integrated network of Apple Macintoshes. Collaboration will shortly commence with two other companies and a university department to study the potential for applying AI techniques to drug design. (Ref: 63)

We are looking for the following attributes and qualifications:

- First degree in chemistry or biochemistry
- PhD and a number of years drug design experience, preferably in industry
- Broad knowledge of medicinal chemistry and computer systems used in molecular design
- Good communications with bench scientists
- Ability to work with little supervision and to play a major role in the company's drug design process

In addition to an excellent salary the company offers the following benefits:

- First class pension scheme
- Free Life Assurance ● Share Option Scheme
- Individual health care scheme
- Social Club ● 25 days' holiday

Please write with c.v. to:

Rod Cook,
Head of Personnel,
British Bio-technology Limited,

alaries depending on experience range from 29.000 to 35.000 M/p.a Applications including curriculum vitae, education or revious experience and name of referee should be sent to **Prof. r. K. Moelling, MPI fur Molekulare Genetik, Ihnestr. 73, D-1000 erlin 33.** (W6599)A

FACULTY POSITION

DEPARTMENT OF GEOLOGY AND GEOPHYSICS
UNIVERSITY OF CALIFORNIA, BERKELEY

Applications are invited for a tenure track faculty position at the junior level in the Department of Geology and Geophysics, pending final budgetary approval. This appointment could also be made with tenure. All areas of geology will be considered. Applications along with curriculum vitae, statement of research interests, representative reprints, and the names of three references should be sent by 15 December 1989 to: **Dr. William E. Dietrich, Chair, Search Committee, Department of Geology and Geophysics, University of California, Berkeley, CA 94720.**

The University of California is an Equal Opportunity, Affirmative Action Employer. (NW4385)A

PRODUCTION MANAGEMENT OPPORTUNITIES
(AUSTRALIA)

CSL is an Australian owned company responsible for the development, manufacture and marketing of human and veterinary pharmaceuticals and diagnostic products

A prime function of the organisation is to provide to the Australian community a range of therapeutic products derived from human blood plasma which is supplied by the Australian Red Cross Society

The blood product range includes coagulants immunoglobins and plasma volume expanders. A new state-of-the-art manufacturing plant which will cater for Australia's needs into the next century is now under construction

Two suitably qualified Scientists, preferably with large scale manufacturing experience, are sought as members of our Blood Products management team.

PRODUCTION MANAGER

The successful applicant will be responsible for the manufacture of our range of Blood Products, involving the activities of a team of about 100 persons including several professional scientists. The most important aspect of this role will be to utilise these resources within the present plant to improve its operating efficiency and to extend the output of our Blood Product range consistent with corporate strategies and user needs. The work also involves close collaboration with a small team of scientists who carry out R&D projects aimed at improving the purity, yield and efficacy of therapeutic blood proteins. The Production Manager will also provide essential design information to the CSL team involved in the construction of our new Plasma Fractionation plant.

ASSISTANT PRODUCTION MANAGER

Assist the Manager in running the facility particularly in the areas of good manufacturing practice compliance, documentation, staff training, budgeting and cost control.

POSITION REQUIREMENTS

Both positions require planning and leadership ability together with above average interpersonal skills.

Tertiary qualifications in either chemistry, microbiology, biochemistry or a related discipline is expected; some post-graduate training in protein chemistry would be highly regarded although not essential

Familiarity with the Australian Code of Good Manufacturing Practice

The successful applicant for the Production Manager's position will have some years experience in an industrial/manufacturing setting which involved perhaps aseptic processing techniques or large scale separation and purification of products relevant to the pharmaceutical industry

CSL, a Government-owned business enterprise, is an equal opportunity employer An attractive package is available to suitable applicants. Conditions of service include four weeks annual leave, long service leave and participation in a generous superannuation scheme

Enquiries may be directed to Mr. R. Herrington, Technical Manager on Tel: (International) +61 3 389 1456 or Fax: (International) +61 3 389 1434

Written applications should be addressed to the Blood Products Personnel Officer, CSL, 45 Poplar Road, Parkville, Victoria 3052, quoting reference 420/1 - Production Manager or 420/2 - Assistant Production Manager.

CSL

Putting Quality First (W6590)A

GLASGOW: EUROPEAN CITY OF CULTURE 1990
UNIVERSITY OF GLASGOW

Departments of Genetics and Medical Genetics
Post-Doctoral Research Assistant

A 3 year post-doctoral position is available to evaluate and apply a novel "subtraction" method for cloning human genes of medical significance. The project is funded by the MRC as part of the Human Genome Mapping Programme. Candidates must have previous experience in molecular biological techniques but experience with human systems is not essential.

Informal enquiries or formal applications including full CV and names and addresses of two referees may be made to **Dr. K. Kaiser, Department of Genetics, University of Glasgow, Church Street, Glasgow G11 5JS;** Tel 041–339 8855 ext. 5112, or to **Professor J.M. Connor, Department of Medical Genetics, Yorkhill, Glasgow G3 8SJ;** Tel: 041–339 6996. (1665)A

UNIVERSITY OF DURHAM
DEPARTMENT OF BIOLOGICAL SCIENCES

POSTDOCTORAL RESEARCH ASSISTANT IN PROTEIN CHEMISTRY/BIOCHEMISTRY

A postdoctoral research scientist is required for a three year AFRC funded project to study the structure and interfacial properties of proteins involved in the stabilisation of lipid storage bodies in plants and animals A variety of physical techniques, including IR, CD, NMR and UV spectroscopy, X-ray and light scattering and thin-film measurements, will be used. Biochemical and molecular techniques will include amino acid sequencing, structure predictions and possibly protein engineering. Candidates with a good background in some or all of the above methods may enquire informally to Dr. J Murphy (tel. No. 091-374-2428.

The appointment will be within the range £10,458-£12,381 on the Research and Analogous IA scale.

Applications (three copies, including full CV and the names of three referees) should be sent to the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE** (091-374-2265) not later than *Friday, 10th November, 1989.* (Please quote reference BS10). (1816)A

INSTITUTE OF PSYCHIATRY
(University of London)

POSTDOCTORAL MOLECULAR BIOLOGIST

A post is available a part of a group investigating genetic influences in mental illness. Work will involve the development of candidate gene probes for mental illness and their application to genetic mapping. Applicants should be molecular biologists with experience in cloning, sequencing, PFGE an advantage.

Salary in the range £10,458 – £11,736 pa plus £1650 pa London Weighting.

Further details may be obtained from Dr Roger Marchbanks or Dr Stephen Whatley, Department of Neuroscience (Tel: 01-703 5411 ext 3258).

Applications in the form of a curriculum vitae and the names of two referees should be sent to the **Personnel Office, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF.**

Closing date 2 November 1989. (1822)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
Department of Cellular and Molecular Sciences
Divisions of Communicable Diseases and Immunology
RESEARCH ASSISTANT GRADE IA

This new post is funded by the Medical Research Council for 3 years to provide technical and scientific support and organisation of the P3 laboratory being commissioned to work on HIV infection. The post will also involve research work on HIV infection in macrophages under the supervision of Dr George Griffin

Candidates for the post should have scientific research experience including tissue culture and basic biochemical techniques. Experience in running a high containment laboratory would be useful but not essential, since full training will be given.

Salary will be on scale IA starting at £12,738 including London Allowance. Further details and an application form from the **Personnel Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE,** 01 672 9944 ext 56020 Closing date 3 November 1989

Please quote reference 133/89. (1789)A

Ideal opportunity for talented individual to take first step from an academic to a commercial role in marketing support.

CJRA

APPLICATIONS CHEMIST

M4 CORRIDOR, BERKS **£17,500-£23,000 + benefits**

TECHNICAL EQUIPMENT AND SYSTEM SUBSIDIARY OF MAJOR INTERNATIONAL DIVERSIFIED GROUP

We invite applications from individuals in their mid to late 20's and likely to hold a PHd in Chemistry/Life Sciences, with experience of liquid state nuclear magnetic resonance spectroscopy, including modern 2D techniques. This experience may have been gained within the medical systems industry or in a research/ university background. Working as part of the Marketing Function, the successful candidate will primarily be involved in applications development using high resolution NMR Spectrometers. In addition, you will provide pre and post sales support, demonstrating technical equipment to customers – you will also be required to give similar demonstrations to universities and at exhibitions. Strong presentation and communication skills are key and a working knowledge of German will be useful but not essential. This position will be of particular interest to those with research/academic contacts in this field. Initial salary negotiable £17,500-£23,000, contributory pension, free life assurance, free private medical insurance and assistance with removal expenses if necessary. Applications in strict confidence under reference ACDIE 22723/N will be forwarded unopened to our client unless you list companies to which they should not be sent in a covering letter marked for the attention of the Security Manager: CJRA (1837)A

UNIVERSITY OF NEWCASTLE UPON TYNE
GASTROINTESTINAL DRUG DELIVERY RESEARCH CENTRE

This interdisciplinary Centre is supported through the LINK Programme in Selective Drug Delivery and Targeting, funding by an SERC/MRC/DTI/ Pharmaceutical Industry consortium. The programme of research focuses on the nature of the gastrointestinal epithelial barrier. The experimental approach is based on modern cellular and molecular biological techniques, including human cultured cell lines and membrane biochemistry.

Research Associate

A position is available immediately for an enthusiastic scientist to investigate microbial/intestinal interactions, including identification of intestinal antigens involved in microbial binding to and subsequent endocytosis in intestinal epithelial cells. Experience in relevant aspects of cell biology, including immunology, will be an asset.

The appointment will involve inter-disciplinary interaction within the Centre, and is available for up to 4 years. The successful applicant will be appointed to the Grade 1A scale (£10,458-£16,665 p.a.), and should possess or be about to submit for a PhD. Applications are also welcome from graduates with suitable research experience, who would be appointed on the Grade 1B scale (£9,816-£12,381 p.a.).

Applications, including full c.v. and names of two referees, should be sent to **Dr B H Hirst, Gastrointestinal Drug Delivery Research Centre, Medical School, Newcastle upon Tyne, NE2 4HH** Informal enquiries will be welcomed by Dr N L Simmons (091-222-6000 ext. 6999) and Dr B H Hirst (091-222-6993). (1818)A

AMERICAN CANCER SOCIETY

BASIC CANCER RESEARCH EMINENT SCHOLAR CHAIR
UNIVERSITY OF FLORIDA
(Edward R. Koger Professorship)

Applications are invited for candidates to fill a faculty professorship in Basic Cancer Research, funded through an Eminent Scholar Chair sponsored by the American Cancer Society. The candidate should have demonstrated a strong commitment to academic medicine Candidates must hold an Ph.D , M.D., or both, and have an accomplished research record in the investigation of fundamental processes of neoplasia. A highly interactive individual would be desirable to take advantage of the research collegiality available at the University of Florida. The scholar could be appointed in a basic science department or jointly with a clinical department. Salary is negotiable and will be based on credentials. Deadline for receipt of applications is January 15, 1990.

Candidates for this position should be nominated or they should submit a letter of application stating teaching and research goals, and include a curriculum vitae and at least three names of reference to **Edward M. Copeland, III, M.D., Chairman of Professorship Search Committee, Department of Surgery, Box J-286, JHMHC, Gainesville, FL 32610.** (NW4319)A

INSTITUTE FOR GENETICS, UNIVERSITY OF COLOGNE, WEST-GERMANY

Post doctoral position

A position is immediately available for two years for recent or experienced Ph.D. (genetics, biochemistry, or equivalent training) to study molecular neurogenetics of brain-specific gene expression in the CNS of the mouse. Experience in current molecular genetic techniques is prerequisite.

Send vita and names (+ telephone numbers) of 2 references to **Prof. W. Wille, Institut für Genetik, Universität zu Köln, Zülpicher Str. 47, D-5000 Köln 1, West-Germany.** (W6571)A

The Department of Pharmacology at The University of Iowa College of Medicine has

Tenure-track Faculty Positions

available at any level. The Department has strength in cardiovascular pharmacology, endocrinology, neurobiology and toxicology. The appointment is intended for an individual applying molecular biology in one or more of these areas. The successful candidate is expected to develop a vigorous, externally-funded research program, and to participate in the teaching programs Send a vita, list of publications, statement of research interests, and the names/addresses of three references to **Search Committee, Department of Pharmacology, The University of Iowa, Iowa City, IA 52242.** Wheelchair accessible campus Women and Minorities are encouraged to apply. *The University of Iowa is an Equal Opportunity/ Affirmative Action Employer* (NW4368)A

Our Science Division needs an astronomer with computer experience.

The European Southern Observatory (ESO) is an intergovernmental organization, responsible for astronomical research in the southern hemisphere. The eight Member States of the ESO are Belgium, Denmark, France, Italy, The Netherlands, The Federal Republic of Germany, Sweden and Switzerland. The ESO occupies a leading position in the world scientific community as the first European astronomical centre. Its research is of use for a wide range of sciences as well as industry.

EUROPEAN SOUTHERN OBSERVATORY

ESO is looking for a (m/f)

SCIENCE APPLICATIONS PROGRAMMER (ref.: ESD 306)

to start work as soon as possible at its Headquarters in Garching near Munich, Federal Republic of Germany. ESO staff have an opportunity to make the very most of their talents and enjoy highly favourable working conditions: an international environment, advanced technologies and a creative atmosphere.

Assignment: the successful candidate will work within the **Image Processing Group of the Science Division.** Responsibilities include the development, support and maintenance of application programs and procedures in the MIDAS (Munich Image Data Analysis System) image processing system with emphasis on spectroscopy and data bases. Duties will also involve the maintenance of user documentation and manuals for MIDAS, plus general support of the system's usage.

Experience and knowledge: the person sought must have a university degree in physics or astronomy. Experience in scientific application programming, plus the use of either UNIX or VAX/VMS systems is required - along with a firm knowledge of FORTRAN programming. Some experience with the C language will be an advantage. A good working command of English is indispensable. The use of French or German will be helpful.

Remuneration: the remuneration for this post is commensurate with the background, experience and family status of the accepted candidate. The basic tax-free monthly salary will be between 4,820 DM and 7,233 DM, plus an additional non-resident allowance, and other allowances depending on family status.

Although preference will be given to nationals of the ESO Member States, no nationality is a priori excluded.

Applications, indicating the reference number, should be submitted before **October 31, 1989,** to: Personnel Administration and General Services, European Southern Observatory, Karl-Schwarzschildstraße 2, D-8046 Garching near Munich, Federal Republic of Germany. Tel. (89) 320.06 216-8.

The position is initially for t years but can be extended Applications, including C.V., list of pul cations and names of two referees, shou be sent to. **Prof. Dieter Kabelitz, Institu of Immunology, University of Heidelbe Im Neuenheimer Feld 305, D-6900 He elberg, FRG.** (W6592)A

THE CHINESE UNIVERSITY OF HONG KONG

Applications are invited for the following posts:

Lecturers in Physiology

Applicants are expected to have a medical degree, or a Ph.D. in Physiology or a related field. The Department of Physiology teaches a two-year Physiology Course as part of the pre-clinical Medical Course and participates in an intercalated degree course for medical students. Plans are currently under consideration to introduce a science course. The research field in which the department is currently engaged and for which it is equipped include: endocrine and reproductive physiology, gastro-intestinal physiology and nutrition, muscle physiology, renal and acid-base physiology as well as somato-sensory physiology. The appointee is expected to participate in teaching physiology outside his research field. The successful applicants are expected to assume duty in May, 1990 or as soon as possible thereafter.

Annual Salary and Fringe Benefits:

Lecturer: HK$233,700 – 265,200 by 2 increments BAR
HK$280,920 – 390,600 by 7 increments
(Approx. exchange rate: £1=HK$12.05; US$1=HK$7.8).

Starting salary will depend on qualifications and experience

Benefits include long leave, annual leave, sick leave, superannuation (University 15% of salary; appointee 5%), medical benefits, education allowance for children, and housing allowance for an appointee whose annual salary is HK$249,480 or above. An appointee on overseas terms of service is entitled to have passage benefits for himself/herself and his/her dependents

Application procedure:

Applications should be made out in duplicate, giving full particulars, experience as well as the names and addresses of three references, and sent together with copies of certificates/diplomas, testimonials and recent publications to the **Personnel Section, The Chinese University of Hong Kong, Shatin, Hong Kong** before November 30, 1989. Please quote the reference number 87/509/2/89 and mark 'Recruitment' on cover.

ASSISTANT/ASSOCIATE PROFESSOR
BANTING AND BEST DEPARTMENT OF MEDICAL RESEARCH
UNIVERSITY OF TORONTO

The Banting and Best Department of Medical Research, is seeking candidates for the position of Assistant/Associate Professor (Tenure stream). The position is available July 1 1990 and will carry an initial appointment of five years at a competitive salary.

Candidates should have a strong research background and be prepared to develop a research program in an area related to the Molecular Basis for Cellular Regulation, including Molecular and Cellular Aspects of Endocrinology, Mechanisms of Signal Transduction, Surface and Intracellular Receptors, Control of Growth and Differentiation, Diabetes Research, or Regulation of Gene Expression. The successful candidate will be expected to attract independent research grants, to spend at least 7.5% of his/her time in research and to participate in graduate and undergraduate training. *The University of Toronto encourages both women and men to apply for positions.*

Applicants should forward a Curriculum Vitae, an outline of research interests and arrange for three letters of reference to be sent directly to **Dr. David H. Maclennan, Professor and Chairman, Banting and Best Department of Medical Research, University of Toronto, 112 College Street, Toronto, Ontario, Canada M5G 1L6.**

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents to Canada, but foreign applications are encouraged.

(NW4382)A

Medizinische Hochschule Hannover (MHH)
Institute for Molecular Biology

GROUP LEADER

(Hochschuldozent, C2 auf Dauer)

The newly established "Institute for Molecular Biology" at the MHH in Hannover, W. Germany, invites applications for a tenured group leader position in the area of eukaryotic molecular biology. The successful candidate is expected to establish an active, independent research programme in the field of gene regulation, growth control, or differentiation.

Applications for independent research grants (Drittmittel) will supplement the core funds provided. Opportunities for teaching exist in the curricula of medicine and biochemistry. The appointment requires Habilitation or an equivalent qualification.

Applicants should send a curriculum vitae, three significant reprints, an outline of research plans, and the names of three references to:

Prof. Dr. A. Nordheim
current address:
ZMBH, University of Heidelberg
Im Neuenheimer Feld 282
D-6900 HEIDELBERG, FRG

Deadline for receipt of applications is November 30, 1989. (W6579)A

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
INFLAMMATION GROUP/GASTROINTESTINAL SCIENCE RESEARCH UNIT

POST DOCTORAL RESEARCH FELLOW

This post is funded by the National Association for Crohn's and Colitis and the successful applicant will join a group studying oxygen free radicals in inflammatory bowel disease. Methods used include electron spin resonance, chemiluminescence and cytochrome c assays of rectal mucosal explants and dialysates Experience in these and related techniques would be an advantage (but not essential).

Salary will be £10,458-£13,527 (depending on experience and age) plus London Weighting.

Initially the appointment is for 2 years Further particular should be obtained from Dr D S Rampton (01-377 7442) or Professor D Blake (01-377 7765) CV and names and addresses of two referees should be sent to **Miss Bailey, Bone & Joint Research Unit, 25-29 Ashfield Street, London E1 2AD.**

Closing date. 27 October 1989 (1790)A

INSTITUTE OF OPHTHALMOLOGY
DEPARTMENT OF CLINICAL OPHTHALMOLOGY

POST-DOCTORAL RESEARCH FELLOWSHIP

Enthusiastic scientist required to join us to examine the role of aldose reductase in the pathogenesis of diabetic retinopathy, using immunohistochemical and molecular biology techniques, in which training can be given. The post is for three years in the first instance.

Applications, enclosing a cv with the names and addresses of two referees to should be sent to: **Dr. Susan Lightman, Institute of Ophthalmology, 17-25, Cayton Street, London, EC1V 9AT** to whom formal enquiries may be made on 01-387 9621 ext. 274. (1821)A

Senior Scientists in Biomedical Science — Kanagawa, Japan

We invite applications and/or nominations for the positions of senior scientists of the Institute for Biomedical Science The Institute, now being reorganized, will consist of four divisions: and we call candidates for the following three divisions:

1. **Division of Molecular and Cell Biology**
2. **Division of Bioengineering and Biomedical Materials**
3. **Division of Artificial Organs and Organ Transplantation**

The Institute is one of the three Centers constituting the parent center, Terumo R & D (Director General: Tetsuzo Akutsu, M.D., Ph.D. and 500 researchers). The new R&D building (44,146 sq. meter) is under construction and will be open in December, 1989. It is located in the town of Nakai, Kanagawa Prefecture, one-hour drive away from Tokyo. The town is situated on one of the best geographical environments to live in Japan with an excellent view of Mt. Fuji in the west and Sagami Bay in the south.

TERUMO CORPORATION is a leading manufacturer with an extensive product lineup including artificial organs, pharmaceuticals, transfusion and infusion products, medical electronics, labo products and medical disposables. Terumo has manufacturing R&D and distribution facilities in Japan, U.S.A., Belgium and Australia.

QUALIFICATIONS include a Ph.D., and at least seven-year experience in one of the three above-described specialized areas, and an excellent record of scientific achievement. Successful candidates will have a chance to be promoted to the Division Chief, who is expected to have supervisory responsibilities directing junior staff.

SALARY will be commensurate with experience and qualifications We offer house accommodation, and benefits package together with the opportunity to work in our newly constructed superb facilities equipped with modern technologies.

A letter of application, C.V , list of publications, three professional referees, and your portrait should be sent by the end of November, 1989 to the following address:

Yutaka Tomita, Managing Director,
Technical R & D Division,
Terumo Corporation,
44-1, 2-chome, Hatagaya,
Shibuya-ku, Tokyo 151, Japan.
Phone: 03(374)8020, Fax: 03(374)7493.

Applications will be reviewed continuously until suitable candidates are hired. Promising candidates will be contacted for further discussions on the terms of employment contract.

(W6595)A

TERUMO CORPORATION

UNIVERSITY OF EDINBURGH
FACULTY OF VETERINARY MEDICINE

LECTURER/SENIOR LECTURER IN VETERINARY REPRODUCTION

Applications are invited from veterinary graduates with experience in reproduction for a post based at the Veterinary Field Station, Royal (Dick) School of Veterinary Studies, Easter Bush, Roslin. The appointee will be expected to head the reproduction research programme and play a role in postgraduate and undergraduate training and clinical work It is likely that the successful candidate will have a Ph.D. or have demonstrated research expertise and will have an active programme of investigation.

The post is available from 1st October 1989. Salary will be on the lecturer/senior lecturer scale £16,014-£24,285 per annum, with placing according to qualifications and experience.

Particulars of appointment may be obtained from the **Personnel Officer, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS,** with whom applications (four copies including a *curriculum vitae* and the names and addresses of three referees) should be lodged no later than 20th October 1989.

FACULTY POSITIONS IN PHARMACOLOGY

The Department of Pharmacology at the University of Texas Southwestern Medical Center at Dallas seeks applicants for tenure-track positions at the level of assistant or associate professor. Applicants must have a relevant Ph D. or M.D. degree and postdoctoral training and must show evidence of a firm commitment to a career in independent research. We are particularly interested in applicants who plan to apply techniques of cellular or molecular biology or biochemistry to fundamental problems of pharmacological interest Responsibilities include teaching graduate and/or medical students after the first year of employment. Send curriculum vitae, list of 3 referees and a brief description of proposed research to: **Alfred G. Gilman, Chairman, Department of Pharmacology, University of Texas Southwestern Medical Center at Dallas, 5323 Harry Hines Boulevard, Dallas, Texas, 75235-9041.** *An Equal Opportunity/Affirmative Action Employer.* (NW4289)A

JOINT GLOBAL OCEAN FLUX STUDY

EXECUTIVE SCIENTIST

Applications are invited for the position of JGOFS Executive Scientist An international scientific office for the Joint Global Ocean Flux Study is being established at the Institut fur Meereskunde, Kiel University, the FRG. Applicants should possess a PhD and substantial experience in marine science and should be willing to re-locate to Kiel for a period of at least two years.

The JGOFS Executive Scientist will work in close cooperation with the Chairman, other JGOFS Committee members and with the JGOFS Executive Secretariat in Halifax. The incumbent will provide staff support to the JGOFS Committee and will be responsible for assisting it in the identification, assessment, discussion and development of scientific issues related to the Study, for scientific liaison with other international programs (e.g. WOCE, IGBP, etc.), for interactions with national JGOFS planning groups, etc.

Opportunities for the initiation and/or continuation of flux-related research are available. The incumbent will be encouraged to participate in the analysis of evolving JGOFS data bases from the North Atlantic Pilot Study and time series stations. The Institut fur Meereskunde is a designated archive for JGOFS Pilot Study observations with institutionally supported access to VAX and CRAY computing facilities.

Interested individuals should contact Elizabeth Tidmarsh, the Executive Secretary of JGOFS, for additional information as soon as possible:

UNIVERSITY OF CAMBRIDGE : DEPARTMENT OF MEDICINE
Assistant Director of Research in Human Molecular Genetics
(Senior Non-Clinical Scientist)

Applications are invited for the post of Assistant Director of Research in the newly refurbished laboratories in the Department of Medicine. The principal interest of the group led by Professor T.M Cox is the molecular basis of metabolic diseases in man and the successful candidate will be expected to have strong background in molecular genetics The appointee will participate in research and assist in the supervision of laboratory work by graduate researchers within the group. Development of collaborative links with other scientific laboratories and departmental groups on the Addenbrooke's site will be actively encouraged.

The post is available from 1 October 1989 and tenable for five years in the first instance. Salary in the range £14,169-£20,469 according to age

Further particulars may be obtained from the **Secretary of the Clinical School, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ** (0223-336727) to whom candidates should send their applications (15 copies), together with the names of three referees by 8 November 1989.

The University is an equal opportunities employer (1791)A

THE UNIVERSITY OF WARWICK
DEPARTMENT OF BIOLOGICAL SCIENCES

POSTDOCTORAL RESEARCH FELLOW

A biochemist/microbiologist with experience in protein purification techniques is required as soon as possible for a project jointly supervised by Professor D. P. Kelly (Warwick) and Dr. R Cammack (King's College London). The aim is to determine the structure and function of a novel manganese-protein and other enzymes in the thiosulphate-oxidizing system of *Thiobacillus versutus*. The Fellow will be based at Warwick, where organism cultivation, enzyme purification, kinetic and some chemical assays will be done. The Fellow will also work at King's College where electron spin resonance spectroscopy studies will be carried out.

The appointment will be for up to three years on the Research IA scale. £10,458 to £16,665 p.a. Further particulars can be obtained by telephoning Professor Kelly on 0203-523181 (direct line) Application forms from the **Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL** quoting Ref. No SERC/DPK/14. Closing date: 2 November 1989.

Glaxo IMB

GLAXO INSTITUTE FOR MOLECULAR BIOLOGY

The Geneva biotechnology research unit of the largest U.K. pharmaceutical group is recruiting

YEAST RESEARCHERS

to investigate the molecular basis of signal transduction via expression of heterologous genes in yeast

Significant experience of the molecular and cell biology of yeast is required. Previous experience with signal transduction would be an advantage. The ideal candidate will have a PhD plus post-doctoral experience with a proven track record.

The Glaxo Institute for Molecular Biology carries out research to support the discovery of effective new medicines. The Institute has an international staff of over one hundred, grouped in teams of specialists from several domains of modern biology.

We offer an excellent salary and benefits package, with opportunities for career development in one of the most attractive parts of Europe.

If you are interested in this position, please send your Curriculum vitae with a list of publications and the names of three references to: Rita Gloor, Personnel Manager, GLAXO IMB S.A., 46, route des Acacias, 1211 Geneva 24, Switzerland.

(W6566)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)
DEPARTMENT OF PHYSIOLOGY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Research Assistantship funded by the MRC for 2½ years for studies of the physiology and pharmacology of inhibitory postsynaptic potentials in thalamus. The laboratory has a long term interest in the physiology and pharmacology of excitatory and inhibitory amino acid mediated synaptic transmission. Techniques include: intracellular recording, current and voltage clamp, iontophoresis, spike triggered averaging, intracellular dye injection and reconstruction of neurones. Experience of some of these techniques would be helpful but enthusiasm for neuroscience, willingness to learn and aptitude are more important. A fully operational rig is available for this project in a well funded laboratory in which the required techniques are in routine use

Salary is on the 1A scale.

Informal enquiries to **Dr. Alex Thomson, Department of Physiology, address as below, 01–431–5269.**

Applications (***TWO copies of C.V.*** plus names and addresses of two referees) should be sent to the **School Office, R.F.H.S.M., Rowland Hill Street, London NW3 2PF.** Please quote ref. *P/PRA/59.* (1749)A

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)
DEPARTMENT OF MEDICINE
GRADUATE RESEARCH ASSISTANT

required to work in an established neurotransmitter/hormonal peptide research laboratory. The work will include the measurement of brain and gut regulatory peptides, including CGRP, and the investigation of their physiological and biochemical relationship to human disease Preference will be given to candidates who are expecting to obtain a good honours degree in a relevant discipline such as biochemistry or physiology. The possibility of studying for a higher degree does exist.

Salary in the range £7,130-£10,238 + £1,267 London Allowance p.a.

Please send full CV with name of two referees to the **Personal Office, Royal Postgraduate Medical School, Ducane Road, London W12 0NN** quoting reference AMN3.

Closing Date: 26.10 89 (1801)A

nature

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE seeks a NEWS REPORTER

Essential qualifications:
* A good science education
* Capacity to write fluently

Other relevant qualifications:
* Experience as a journalist
* A second European language
* First-hand knowledge of research

Salary by negotiation. London-based, but the successful applicant must be prepared to travel. Apply with full *curriculum vitae* and names of two referees to the **Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF** as soon as possible. (1780)A

EMORY UNIVERSITY

The **Department of Chemistry** of Emory University invites applications for a tenure-track **Assistant Professor** position in **Organic Chemistry**, beginning in Fall, 1990. Candidates in all fields of Organic Chemistry are encouraged to apply The successful candidate will be expected to develop an outstanding and productive program of creative and original research. A commitment to excellence in undergraduate and graduate teaching is required. Applicants should send a curriculum vitae, a statement of research plans and should arrange for the submission of three letters of recommendation to: **Professor F. M. Menger, Department of Chemistry, Emory University, Atlanta, GA 30322.** All applications will be reviewed beginning November 1, 1989. Emory University is an Equal Opportunity/Affirmative Action employer. (NW4372)A

UNIVERSITY OF LEICESTER

Department of Biochemistry, Biological NMR Centre & Centre for Research in Molecular Recognition

POST-DOCTORAL AND TECHNICIAN POSITIONS

Molecular Recognition and Protein Structure-Function Relationships:
NMR Spectroscopy, Molecular Biology, Molecular Modelling

Positions are available in an active and expanding interdisciplinary group using a variety of techniques to study protein structure and function, especially the molecular basis of protein specificity. Particular emphasis is placed on the use of two-dimensional nmr spectroscopy, in combination with site-directed mutagenesis, kinetics and molecular modelling.

Excellent facilities are available for all aspects of this work: preparative & molecular biology laboratories, 500 MHz and 600 MHz multinuclear nmr spectrometers, dedicated computers (including Alliant FX40/3) and molecular graphics (E&S PS330, Silicon Graphics IRIS workstations).

Six post-doctoral positions are now available:

Molecular biologist
Mutagenesis and specificity of dihydrofolate reductase.

Protein chemists, enzymologists & nmr spectroscopists
Nmr studies of dihydrofolate reductase and of the E coli trp repressor.

Nmr spectroscopists
Improvements in nmr methods for the study of protein structure & interactions. One of the positions is for an experienced nmr spectroscopist who will also play an important role in assisting external users of the Centre's spectrometers.

Molecular modelling and software development
Modelling & simulation of protein-ligand interactions and mutant proteins, including the development of procedures for the utilization of nmr data. One of the positions will involve management responsibility for the computing and molecular graphics facilities of the Centre for Research in Molecular Recognition.

Applicants should have degrees in an appropriate subject, and ideally have experience in one of the areas identified above (not necessarily nmr) The positions are available immediately for periods of 3–5 years, with salaries in the IA range £10,458–£16,665 p.a depending upon age, qualifications and experience.

Research Technician
In addition, two positions are available immediately for technicians (grade C) for work in protein purification and molecular biology; experience in these areas would be a considerable advantage. Applicants should have three years relevant experience and a minimum of ONC or equivalent; applicants are welcome from recent graduates for appointment as graduate trainees. Salaries will be in the range £7,479–£8,645; graduate trainees will receive an initial £6,939 p.a

Applications should be sent to **Professor Gordon Roberts, Department of Biochemistry, University of Leicester, Leicester LE1 7RH, U.K.** to arrive by 15 November 1989 Anyone interested is urged to contact Professor Roberts for further information· Telephone (0533) 523054; Fax (0533) 523013. (1829)A

FEDERAL VACCINE – INSTITUTE, BASEL
EIDG. VAKZINE – INSTITUT, BASEL

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the above post available immediately or on an agreed date. The project, funded by the Swiss National Science Foundation, involves studies on the

molecular basis of the biological variability of classical swine fever virus

Experience in molecular biology is required.

The initial appointment will be for one or two years. Salary is according to the Swiss National Science Foundation (starting with SFr. 57.000 per annum).

Please send CV, bibliography, a brief statement of research experience, plus names and addresses of two references to:

Eidg. Vakzine-Institut
Postfach CH-4025 BASEL

Informal enquiries about the post may be made by telephone to Dr. M. Ackermann (0041-61-578282). (W6591)A

UNIVERSITY OF OXFORD

Following the appointment of Professor C.J. Leaver to the Sibthorpian Chair of Plant Sciences, two further posts in the department of Plant Sciences are now to be filled from 1 October 1990 or such later date as may be arranged.

Readership in Plant Science

The electors are looking for candidates with interests in the molecular, biochemical and physciological processes underlying higher plant growth and differentiation Stipend on the scale £21,489 to £24,285 per annum. A college association will be available.

Applications (ten typed copies, or one from overseas candidates) naming three referees, should be sent by 15 November 1989 to the **Registrar, University Offices, Wellington Square, Oxford, OX1 2JD,** from whom further particulars may be obtained.

University Lecturership in Plant Science in association with Magdalen College

Preference will be given to candidates with an interests in Plant Biochemistry and/or the application of molecular genetic techniques to the understanding of the regulation of plant metabolism during plant development. Stipend according to age on the scale £10,458 to £21,852 per annum. The post may be held jointly with a tutorial fellowship at Magdalen College.

Applications (eight typed copies, or one from overseas candidates) naming three referees, should be sent by 15 November 1989 to **Professor C.J. Leaver F.R.S., Department of Plant Sciences, South Parks Road, Oxford, OX1 3RA** from whom further particulars may be obtained.

Further informal information may be obtained by telephoning Professor Leaver on 031-667-1081, ext. 3304 (1825)A

The University is an Equal Opportunity Employer

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW's HOSPITAL (University of London)
Department of Medical Microbiology
POSTDOCTORAL PROTEIN BIOCHEMIST/ MOLECULAR BIOLOGY

Applications are invited for the above post in the Molecular Biolog Research Laboratory of the Department working on a three year awa from the Medical Research Council. The project would mainly involv purification and molecular characterisation of virulence determinan from the bacterium *Campylobacter pylori*. The postdoctoral positio would suit a protein biochemist although candidates with experience c molecular biological techniques will be considered. The position is tenabl for three years, salary range £14,529-£15,819 (including Londo Weighting).

Applications in writing including CV and summary of research experienc to: **Professor S. Tabaqchali, Department of Medical Microbiology, S Bartholomew's Hospital, West Smithfield, London EC1A 7BE.** (1806)A

University Lecturer *or* University Assistant Lecturer
in the Department of Biological Anthropology

Candidates should have expertise in the genetics of human populations c non-human primates. The person appointed will be expected to teac medical and biological anthropology students in this and related fields c human biology; to develop a laboratory based programme of research and to have an interest in wider aspects of biological anthropology. The pensionable scales of stipends, for persons not ordinarily resident College, are

University Lecturer; £14,169 a year, rising by eleven annual increments t £21,852. There is no grade of Senior Lecturer;

University Assistant Lecturer; £11,088 a year, rising by seven annua increments to £15,372.

Applications, including names of two referees, should be sent to th **Secretary of the Appointments Committee, Faculty of Archaeology an Anthropology, Downing Street, Cambridge, CB2 3DZ,** by November 10t 1989. (1798)A

Laborleiter
für Herz-Kreislauf/Angiologie

In der KNOLL AG haben wir alle pharmazeutischen Forschungsaktivitaten fur den Unternehmensbereich Pharma der BASF-Gruppe konzentriert Dadurch ergeben sich neue, interessante Entwicklungsmoglichkeiten.

Fur die vorklinische Entwicklung von Arzneimitteln auf dem Gebiet Herz-Kreislauf, speziell der Angiologie, suchen wir einen promovierten Mediziner, Veterinärmediziner oder Biologen.

Das Aufgabengebiet umfaßt die experimentelle Abklärung neuartiger Wirkprinzipien, die vertiefte pharmakologische Prufung neuartiger Substanzen sowie die Entwicklung neuer, pathophysiologisch relevanter Modelle.

Neben fundierten pharmakologischen Kenntnissen sind gute englische Sprachkenntnisse, Organisationstalent und Bereitschaft zur Teamarbeit erforderlich

Industrieerfahrung ist von Vorteil; wir sichern Ihnen jedoch eine gründliche Einarbeitung unter Anleitung von erfahrenen Kollegen zu. Weitere Einzelheiten über die Aufgabenstellung und uber die Einkommensmoglichkeiten mochten wir in einem personlichen Gesprach erörtern

Interessierte Damen und Herren bitten wir um Zusendung ihrer aussagefähigen Bewerbungsunterlagen unter Kennziffer „115" an unser Personalwesen

ANTIBODY ENGINEERING
Cambridge, UK

POSTDOCTORAL SCIENTISTS

experienced in recombinant DNA techniques are sought from academic or company backgrounds for a start-up biotechnology company. Experience of immunological methods would also be an advantage but is not necessary. The company will focus on engineering new therapeutic and diagnostic reagents based on antibodies, and should provide an exciting research environment. The company will be located in the Cambridge area and applicants will be offered attractive salaries and participation in a company share scheme.

Please send c.v. (envelope marked: "Antibody Engineering") for the attention of

M. G. Lichten, Esq.
Saffery Champness
Fairfax House,
Fulwood Place, Gray's Inn
London WC1V 6UB

Further information will then be made available to you in due course. Applications will be treated in the strictest confidence.

(W6585)A

THE UNIVERSITY OF GRONINGEN
THE NETHERLANDS

invites applicants for the position of

Professor of microbiology

(vacancy number: 891001/2407)

in the Department of Microbiology of the Biological Centre The successful applicant will lead and coordinate research of the researchgroup "Microbial Physiology" and together with the two colleague professors contribute to the further development of the research and teaching programmes of the Department and its management

Candidates should have a broad knowledge of Microbiology and a special interest in Microbial Physiology, and its application in biotechnological research They should have made significant contributions in this research area and should be prepared to maintain a strong research programme in Microbial Physiology Teaching experience and experience in directing a research group are required

Deadline for application is 11 November 1989.

Letter of application, curriculum vitae and list of publications are to be sent to the Head of the Personnel Department, University of Groningen, P.O. Box 72, 9700 AB Groningen, the Netherlands.

£16,500-£20,000

Further information from Mr John Northover or Dr. Ian Talbot at St. Mark's on 01-608 2323.

Applications, including full cv plus names and addresses of three referees, should be sent to Mr J. Northover, Colorectal Unit, St Mark's Hospital, City Road, London EC1V 2PS no later than 10th November 1989.

Post Doctoral Research Fellowships

Clinical Oncology – Oxford

This is a three year fellowship, working in our Clinical Oncology Unit at Oxford to study molecular mechanisms of angiogenesis. Projects involve characterisation of the effects of growth factors on capillary endothelial cells, especially TGF-ß FGF alone and in combination. Others involve hybridisation and transfection experiments to examine the relative importance of various angiogenic factors in tumour vascularisation.

Ideally, you will have previous experience in tissue culture, molecular biology or biochemical techniques employed in the study of signal transduction. For an informal discussion, contact Dr. Roy Bicknell on 0865 752421. Closing date for applications· 30th November 1989 Ref: 259/R

£13,200-£16,800

Human Tumour Immunology London

Working in the area of T cell biology within a group of five studying the interactions which occur in the thymus between stromal cells and T-cell precursors for 3 years initially. You will also be encouraged to pursue independent research projects and collaborate with members of the Human Tumour Immunology Group, the Tumour Immunology Unit, as well as our main laboratories at Lincoln's Inn Fields, WC2.

Familiarity with standard tissue culture and molecular biology approaches essential. Post doctoral research experience in a related area is desirable but not essential. For further details contact Dr. Amanda Fisher on 01-380 9325. Closing date for applications: 10th November 1989. Ref: 258/R

£14,800-£18,400

To apply for either 259/R or 258/R, applications should be made by sending full cv plus names and addresses of three referees to the Recruitment Officer, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX quoting the appropriate reference.

SMOKING IS ACTIVELY DISCOURAGED.

Cancer Research Campaign

UNIVERSITY OF MANCHESTER DEPARTMENT OF ONCOLOGY

Genetic Associate (Cancer Genetics) and Research Associate in Familial Cancer

Two vacancies exist to work as members of a team concerned with the investigation of human genetic susceptibility to cancer at the Christie Hospital, Manchester. The current research programme includes work on laboratory, epidemiological and clinical aspects of human cancer genetics. Both posts will involve interviewing cancer patients and their families, gathering medical information from other sources, obtaining blood and other biological samples from families for clinical and research purposes, and assisting with data management.

The post of genetic associate will have a clinical slant and will include giving advice on the nature of genetic risks, preparing information for genetic counselling with a clinical geneticist and follow up of families The post of research associate will have an academic base and will be concerned with determination of patterns of inheritance and estimates of risk

Applicants should be graduates in a biological science and nursing experience would be advantageous. Own car essential. Training in interview techniques, venepuncture and other procedures will be given as required.

Salary will be according to age, qualifications and experience.
Research Associate scale: £9,816–£16,665 pa
Genetic Associate scale: £8,255–£15,394 pa (currently under review)

The genetic associate post will be for 3 years in the first instance and the research associate post will be for a fixed term of 5 years. Both posts are funded by the Cancer Research Campaign.

Applications in writing enclosing CV and the names of 2 referees to: Professor D G Harnden, Director, Paterson Institute for Cancer Research or Dr J M Birch, Director, CRC Paediatric and Familial Cancer Research Group at the Christie Hospital and Holt Radium Institute, Manchester, M20 9BX. Further details may be obtained from Dr Birch.

We are an Equal Opportunity Employer. (1823)A

THE UNIVERSITY OF BIRMINGHAM SCHOOL OF BIOCHEMISTRY

RESEARCH FELLOW FOR NMR STUDIES ON PROTEIN-DNA INTERACTION

A Research Fellow is required to work with Dr E I Hyde on a project funded by the Wellcome Trust on the structure and interactions of the DNA binding domains of steroid hormone receptors. Experience in 2D NMR, preferably of macromolecules, or in protein-DNA interactions would be an advantage. The post is available immediately for up to three years, but may be kept open for a suitable candidate. Salary on the Research Fellow 1A range (£10,458-£16,665 plus superannuation).

Informal enquiries can be made to Dr E I Hyde in the School of Biochemistry on 021-414-5393.

RESEARCH OFFICER IN BIOLOGICAL NMR

Applications are invited from suitably qualified candidates to act as a Research Officer for the newly established NMR group studying the molecular mechanisms of cellular regulation processes. A Bruker AMX 500 will be delivered this autumn and access is also available to a Jeol GX 270. Duties will include helping to set up the unit and advising in the various research projects.

Opportunities for personal research in the general area of remit will be available. Technical, computing and other necessary equipment backup will be provided. Applicants will be expected to have a thorough grounding in modern NMR techniques and preferably also molecular graphics. The salary will be on the R1A or R1B scale (£9,816-£16,665) dependent upon qualifications and experience. The position, which is permanent, will be available 1st November, or as soon as possible thereafter.

Further particulars and application forms may be obtained from the **Director of Staffing Services, The University of Birmingham, Edgbaston, Birmingham B15 2TT** (Telephone 021-414-6483 quoting the appropriate Ref. No., 24-hour answerphone) to whom applications including curriculum vitae and the names of two referees should be sent by not later than 30th October.

The Wellcome Trust

Programme Director Infection & Immunity

The Trust wishes to appoint a senior staff member in succession to Dr J G Howard FRS, who has decided to retire in July 1990. The main responsibility of the appointee will be to manage the Trust's programme in the general area of infection and immunity, and he/she will also have special responsibility for the Trust's interests in Tropical Medicine and/or Veterinary Medicine.

The successful applicant will have a strong record of research achievement, hold an established position in one of these areas, and have a good knowledge of the UK academic scene.

The Trust has grown rapidly in the past decade (expenditure for 1989-90 is £56 million) and continuing growth is expected The successful candidate will become part of the team planning the development of the Trust's policies for the support of biomedical research.

Trust Programme Directors are encouraged to retain links with their area of scientific interest by attending scientific meetings, making visits to grant holders etc and they may retain a research interest for up to 20% of their time, at least initially.

Applications are invited from scientific, medical or veterinary graduates There are no age limits but the successful applicant is likely to be within the age range 40-55

Those interested should, in the first instance, contact Dr Bridget M Ogilvie, Director of Science Programmes, before 17th November, 1989, enclosing a copy of their curriculum vitae.

The Wellcome Trust, 1 Park Square West, London NW1 4LT telephone 01-486 4902.

Molecular Biology and Enzymology Research

Senior and Associate Scientists

CIBA-GEIGY's Pharmaceuticals Division is consistently at the forefront in the scientific research and development of life-saving and life-enhancing products. The expansion of our drug discovery efforts using molecular biology and enzymology has created exciting opportunities for Senior and Associate Scientists.

Senior Scientist/ Molecular Biology

Will be responsible for the innovative use of molecular biology in drug discovery programs in inflammation and cardiovascular diseases. Candidates should have a Ph.D. in Molecular Biology, Biochemistry, or related areas. Postdoctoral experience is preferred.

Senior Scientists/ Enzymology

Will be involved in the identification of enzymes as targets for drug development. You will be performing kinetic and mechanistic studies, enzyme purification, assay development and the identification of inhibitors. A Ph.D. in Biochemistry, Chemistry or a related field is required as is several years of postdoctoral experience in a research environment. The ability to interact as a member of a development team is essential. Experience in molecular biology is desirable.

Associate Scientists

Will participate in molecular biology research in our drug discovery programs. An M.S. or B.S. in Biology, Chemistry, or related areas is required. Experience in recombinant DNA methodology including gene cloning and expression, **in vitro** mutagenesis, and DNA sequence analysis is desirable.

CIBA-GEIGY offers competitive salaries, excellent benefits, superb research facilities and opportunity for substantial professional growth. Please send your resume with salary requirements to: **Al Aronson, Staffing Center, CIBA-GEIGY Corporation, Pharmaceuticals Division, Dept. 315, 556 Morris Ave., Summit, New Jersey 07901.** We Are An Equal Opportunity Employer M/F/H/V.

Science Serving Mankind (NW4375)A

CIBA–GEIGY

INSTITUTE OF CANCER RESEARCH
(University of London)

Post-Doctoral Cell Biologist

Applications are invited for a post-doctoral appointment with caree prospects at the Institute of Cancer Research in the Haddow Labora tories, Clifton Avenue, Sutton, Surrey.

The Institute has the largest integrated clinical and scientific group i the United Kingdom working on the cytogenetics and molecula genetics of soft tissue sarcomas. Current emphasis is on the investi gation of translocations specific to the tumour sub-types, but know ledge of the cell types present in these tumours is largely unknown. Having established a source of fresh normal and tumour material we are now in a good position to carry out an indepth study on the biology of these tumours. In addition to teams working on the molecular biology and cytogenetics strong support is available from electron microscopy, flow cytometry and pathology.

Candidates should be experienced in cell biology and preferably have some practical experience in molecular biology. Applications from those interested in being part of a comprehensive, closely interacting team are especially sought.

The salary depending upon qualifications and experience, will be in the range of £12,381 p.a to £20,469 p.a. plus London Allowance of £1,650 p a Informal enquiries may be made by contacting Professor B. A Gusterson on 01-643 8901 ext. 4653.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

To apply, please forward a curriculum vitae, in duplicate, with the names and addresses of two referees, to the **Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL** quoting reference number 10.89.S.NS.49. (1817)A

Cancer Research Campaign

DUNCAN GUTHRIE INSTITUTE OF MEDICAL GENETICS
and
BEATSON INSTITUTE FOR CANCER RESEARCH GLASGOW

Post-graduate Research Assistant Grade 1B

Applications are invited for the post of post-graduate research assistant to work on a collaborative grant studying the role of growth factors in mouse development and carcinogenesis Standard molecular biological techniques and generation of transgenic mice are currently being used as an experimental approach to these systems. Technical experience in either of these areas would be an advantage but new graduates would also be encouraged to apply.

The post is funded by the CRC and is available from January 1st 1990 to August 31st, 1991. MRC conditions of service will apply and the salary will be in the range £9,816–£12,381 depending on age and experience. Work will be based at the Duncan Guthrie Institute.

For further information contact:
Dr. Allan Balmain 041–942–9361
or
Dr Rosemary Akhurst 041–339–6996

Applications including a *curriculum vitae* and the names of two academic referees should be submitted to **Dr. Rosemary Akhurst, Duncan Guthrie Institute of Medical Genetics, Yorkhill, Glasgow, G3 8SJ** no later than November 17th, 1989 (1836)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF BACTERIOLOGY AND MEDICINE
INFECTIOUS DISEASES UNIT

RESEARCH ASSISTANT

Applications are invited for this 2 year post to join a group working on the molecular aspects of aspergillosis, with a particular interest in experimental chemotherapy. The post offers the opportunity to apply molecular biological techniques in the study of the pathogenesis and treatment of this infection. Scientists with a background in mycology or molecular biology (or both!) are invited to contact Dr J Cohen (01-740 3222) for further information. The post is available from 1st November 1989.

Salary £8,884 plus £1,267 London Weighting.

Application forms and further particulars are available from the **Personnel Office, Royal Postgraduate Medical School, Ducane Road, London W12 0NN (tel: 01-740 3204) quoting ref: ABF9.**

Closing Date: 27th October 1989. (1792)A

A key new role for an accomplished manager with a research background, preferably in Plant Sciences, as:

CHIEF DIRECTOR

Executive package includes subsidised housing and car
Cape Town, South Africa

This newly-created appointment has arisen as a result of the amalgamation of the National Botanic Gardens and the Botanical Research Institute. As an autonomous state-aided organisation the new NATIONAL BOTANICAL INSTITUTE will promote the conservation of, and research into, southern African flora. It is a national operation comprising 5 directorates and a staff complement of around 600.

Based at Kirstenbosch Botanical Garden, the incumbent will assume total responsbility for the optimal utilization of resources by continuously evaluating and adapting the strategies and objectives of the Institute and promoting its activities both locally and internationally.

To succeed you will need, first and foremost, an impeccable track record in a managerial capacity in a large, research-orientated environment coupled with: *an appropriate post-graduate qualification; *proven communication and decision-making skills at all levels; *a persuasive, yet flexible approach; *ideally, a marketing/PR bias; *the inherent ability to adapt to a wide range of people and circumstances. It not already proficient in both English and Afrikaans, you will need to acquire the necessary skills within a year.

A top package commensurate with the seniority of the appointment is offered and includes assistance with relocation expenses.

Cape Town is one of the world's most attractive coastal cities with its outstanding educational (primary to tertiary) and cultural facilities; its scenery, beaches and entertainment amenities with the emphasis on outdoor pursuits.

Written applications containing a well-detailed c.v., should ideally be faxed, in assured confidence, to the Chairman of the Board, National Botanic Gardens at (010–2721) 762–3229 or forward by post to him at Private Bag X7, Claremont 7735, Republic of South Africa. Further Information can be obtained directly from Dr P Beezhold at the South African Universities' Office, in London, United Kingdom at telephone 839–3420 or 839–4388. Closing date: 1 November 1989. (W6608)A

NATIONAL BOTANIC GARDENS

MRC
Mammalian Development Unit

Mammalian Embryologist

Applications are invited for a CAREER appointment to this NON-CLINICAL SCIENTIFIC post, tenable at this Unit in the first instance.

Preference will be given to candidates with an interest in post-implantation development or organogenesis. Facilities are available for all aspects of experimental embryology, including in vitro culture, recombinant DNA technology, and production of transgenic mice.

Remuneration will be at an appropriate point on the scales for University non-clinical academic staff. Further information may be obtained from **Dr Anne McLaren, MRC Mammalian Development Unit, Wolfson House (UCL), 4 Stephenson Way, London, NW1 2HE,** Tel. 01-387 9521 with whom applications — including a full CV, detailed research proposals and the names of two professional referees — should be lodged by November 2nd 1989. (1794)A

VACCINE PRODUCTION

CELL CULTURE VIROLOGY

A senior technical position is available within our Production Division, Viral Vaccine Department, to assist in production scale-up of new vaccines from our Research Group, and in on-going production development. Candidates should have a B.Sc. in microbiology with post-graduate laboratory experience in cell culture and virus propagation. Salary will be commensurate with experience, and an attractive benefits program is offered. There is excellent potential for career advancement in this Animal Health Biotechnology company, affiliated to a leading multinational animal and human health corporation.

Please send resume to: **Personnel Manager, Langford Inc., 400 Michener Road, Guelph, Ontario. N1K 1E4.**
(NW4390)A

BIOCHEMISTRY/MOLECULAR BIOLOGY

MEHARRY MEDICAL COLLEGE

Faculty positions are expected to be available in 1990 in the Department of Biochemistry at the level of Assistant or Associate Professor for well-trained or experienced candidates in the following areas: 1 molecular biology of eucaryotic systems; 2. membrane biochemistry or molecular biology of signal transduction; 3. regulatory aspects of cellular and/or metabolic biochemistry. Successful applicants will be expected to develop and/or maintain a funded research program of high quality, to participate in the graduate and professional (medical, dental and allied health) school teaching programs of the Department and to interact with institutional programs in neuroscience and cell/molecular biology. Applicants should send curriculum vitae, names of four individuals who may be contacted for reference, and a summary of potential research projects to: **Ifeanyi J. Arinze, Ph.D., Chairman, Department of Biochemistry, Meharry Medical College, Nashville, TN 37208.** Meharry Medical College is an equal opportunity/affirmative action employer (NW3993)A

THE UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL

SENIOR EUKARYOTIC GENETICIST

The Department of Biology invites applications from outstanding eukaryotic geneticists for a senior faculty position. Generous space in a new building, salary and set-up funds are available. The successful candidate will be expected to conduct a vigorous research program and participate in teaching.

Applicants should send a curriculum vitae and the names of four referees to: **Thomas D. Petes, Chair, Search Committee, Department of Biology, CB# 3280 Coker Hall, University of North Carolina, Chapel Hill, NC 27599-3280.**

Priority will be given to applications received before December 1, 1989. Nominations are also welcome. Applications from minority groups and women are strongly encouraged.

The University of North Carolina at Chapel Hill is an Equal Opportunity/Affirmative Action Employer (NW4366)A

ANTITHROMBOSIS SECTION LEADER-reference 89.179
BIOCHEMISTRY SECTION LEADER-reference 88.332

For many years Kabi has kept a leading position in antithrombosis research with development of such products as heparin, streptokinase, antithrombin, chromogenic peptide substrates and recently low molecular weight heparin We are now expanding our research organisation and are looking for canidates for the positions of leader of our antithrombosis section and leader of our biochemistry section.

The leader of the antithrombosis section will be responsible for development of new antithrombotic drugs and report directly to the R & D director. We are looking for a scientist with an established record of achievement in antithrombosis research or in a related field. Suitable background could be biochemistry, physiology or medicine.

In order to lead the biochemistry section we want a Ph.D with a background in biochemistry or related areas. This section mainly deals with the biochemistry of heparin and heparin derivatives. Previous experience in that field will be regarded as an important merit.

Our research center is located in the attractive city of Stockholm in Sweden. Inquiries about the positions may be made to Vera Rauf, Personnel Department or to the Director of R & D, Professor Lars-Olov Andersson, phone nr 46 8 13 80 00. To apply please write full c.v. quoting reference number. The applications should be sent by 27 October 1989 to

IMMUNO

THE UNIVERSITY OF WESTERN ONTARIO

The University of Western Ontario invites applications for two tenure track faculty positions in the Faculty of Science (one in Plant Molecular Genetics; the other in Animal Molecular Genetics). The rank will be either Assistant Professor or Associate Professor, commensurate with experience. Applications are encouraged from internationally recognized candidates with active research programs which have had a major impact in the molecular genetics of plant or animal systems. A Ph.D. and postdoctoral experience are required. The successful candidate will be expected to play a pivotal role in the expansion of molecular genetics/biology in the Faculty of Science and, to participate in a graduate program in molecular biology between the Faculties of Science and Medicine. Generous research space will be provided in a new science centre currently under construction. Applicants should submit a curriculum vitae, a one page statement of research interests, and the names of three references to: **Dr. W.S. Fyfe, Dean, Faculty of Science, The University of Western Ontario, London, Ontario, Canada N6A 5B7.** Deadline Immigration requirements, this advertisement is directed to Canadian citizens and permanent residents of Canada. Others are encouraged to apply. These positions are subject to budget approval. *An Equal Opportunity Employer.*

(NW4380)A

Technical Supervisor II/Project Scientist needed. Duties would include neurophysiological assessment of the effects of neurotoxicants on the limbic region of the central nervous system. This will be achieved through extracellular hippocampal field potential recordings in unanesthetized animals and the use of chronic electrical seizure model known as kindling Use in vitro hippocampal slice preparation to determine mechanism of toxicant action Evaluate the extent to which disruption of neurophysiology of limbic structures impacts upon an animal's behavior, with emphasis on learning and memory. Supervise and manage 10 technical support staff for physiology, histology, anatomy, biochemistry, and behavioral laboratories in a neurotoxicology division. 8:00 a.m. to 4:30 p.m., 40 hours per week; $735.00 per week. Ph.D. required in Neuroscience, with experience in kindling, longterm potentiation, in vitro slice preparation, lesion work and behavioral testing. One year experience in the job offered required or one year experience as Research Fellow in Neurophysiology. **Job order Number NC 3090287, DOT Code 041-061-094. Apply to Job Service, 516 North Mangum Street, Durham, N.C. 27701, or your nearest Job Service Office.**

(NW4374)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT

Required to help study mechanisms by which DNA supercoiling regulates the expression of certain bacterial genes. The post is available for two years but may be extended.

Salary will be £9,816 to £12,381 per annum, dependent on qualifications and experience.

Applications with C.V. (2 copies) and the names of 2 referees should be sent as soon as possible to the **Personnel Office, The University, Dundee DD1 4HN.** Please quote Ref: EST/441/89/N.

(1809)A

Molecular Virologist

Bovine viral diarrhea virus

For a project on cloning and expression of the BVDV genome, we are seeking an experienced researcher who is interested in a position as visiting scientist in Denmark for one year starting 1 January 1990 The institute has good research facilities and proper funding of the project We are located on a small island in the countryside about 1 hours drive from Copenhagen.

Salary will be commensurate with qualification and experience.

Please send c v. and the names of two referees to: **Dr. Kristian Dalsgaard, Animal Biotechnology Research Center, State Veterinary Institute for Virus Research, Lindholm, DK-4771 Kalvehave, Denmark** before 15 November 1989.

UNIVERSITY OF DURHAM
DEPARTMENT OF GEOLOGICAL SCIENCES

SENIOR RESEARCH ASSISTANT

Applications are invited for a Senior Research Assistant to carry out geological mapping and research in the area covered by Sheet 114 (Scotland), as part of the BGS/UK Academic Mapping Programme. Candidates should have previous research experience working in complex structural and/or metamorphic terrains. A substantial period of fieldwork is anticipated

The post is funded for two and a half years (30 months) by the Natural Environment Research Council.

Salary will initially be in the range £10,458-£12,381 per annum on the Research and Analogous IA scale.

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE** (Tel. 091-374-2265) to whom applications (three copies, including full CV and the names of three referees) should be sent not later than *Wednesday, 1st November, 1989.* (Please quote reference GL2). (1815)A

JOHN INNES INSTITUTE
APPLIED GENETICS
DEPARTMENT

A Higher Scientific Officer is required to join a long range mapping project in pea working with N Ellis. In particular the organization of the sub-telomeric region of a chromosome carrying a 5S RNA gene array at a telomere proximal position will be investigated, the programme relates to other investigations within the Institute and on this site Experience of plant systems is not required, but familiarity with long range mapping technologies would be advantageous.

Further details on the project can be obtained from the Departmental Secretary, Applied Genetics Dept., John Innes Institute. This period appointment will be on the HSO scale £10,678–£14,335, non-contributory superannuation. Candidates should have a 1st or upper 2nd class honours degree and at least 3 years relevant post-qualifying research experience Applications, including the names of two referees should be sent to the Personnel Officer, John Innes Institute, Colney Lane, Norwich NR4 7UH, UK, to arrive not later than 30th October 1989, quoting Ref AG 409.

The John Innes Institute is an equal opportunities employer, and is associated with the AFRC Institute of Plant Science Research. (1849)A

DEAN

Division of Sciences

College of Sciences and Arts

Washington State University

Washington State Universtiy (WSU), the state's land-grant university, invites nominations and expressions of interest for the position of Dean of the Division of Sciences of the College of Sciences and Arts. The Dean is the chief administrative officer of the Division of Sciences which, together with the Division of Humanities and Social Sciences, comprises the College of Sciences and Arts at WSU. The Division's thirteen academic departments and programs include: basic medical sciences, biochemistry/biophysics, botany, chemistry, computer science, environmental science and regional planning, general biology, genetics and cell biology, geology, microbiology, pure and applied mathematics, physics, and zoology. Additionally, several programs are offered through the Division, including chemical physics, general studies (physical science, biological science, and mathematics), geological engineering, plant physiology, statistics, and zoophysiology.

The Dean of Sciences serves principally the University's main campus in Pullman which enrolls 14,000 undergraduate and 2,000 graduate students. The pattern of campus-centered residence living and the attractive natural setting combine to produce a community dedicated to the intellectual and personal growth of students, faculty, and staff. In addition to the central responsibilities on the Pullman campus, the Dean of Sciences will help develop upper-division undergraduate and graduate programs at WSU's new branch campuses in Spokane, Tri-Cities, and Vancouver, Washington.

Leading candidates for appointment as Dean of the Division of Sciences will have an earned Ph.D. (or equivalent) degree and distinguished records of accomplishment in science, preferably including successful experience in university-level teaching, research, and the management of scientific endeavors. Leading candidates will have demonstrated also a strong commitment to the advancement of science education and scientific enquiry within the context of a major research university, and equally strong commitments to the principles of academic freedom, faculty governance, and opportunities for advancement among faculty, students, and staff. Additionally, leading candidates will have demonstrated the qualities of strength, stamina, and enthusiasm, and will be skilled at communicating the needs, interests, and accomplishments of scientific endeavors to a wide range of external as well as internal constituencies.

Nominations and expressions of interest will be accepted until the position is filled. The Search Committee will begin reviewing candidates on November 16, 1989; thus, submissions are encouraged prior to that date. All inquiries and requests for a more detailed position description should be forwarded to: **Dr. Robert V. Smith, Chair, Dean of Sciences Search Committee; c/o Graduate School, French Administration Building Room 324; Washington State University; Pullman, Washington 99164-1030; (509) 335-3535.** The search is being assisted by Dr. John Phillips, Managing Vice President, Education Practice; Korn/Ferry International; Presidential Plaza - Suite 200; 900 - 19th Street, NW; Washington, D.C. 20006; (202) 822-9444. Qualified candidates may be contacted by Dr. Smith, Dr. Phillips, or members of the Search Committee.

All inquiries, nominations, and expressions of interest will be held in strictest confidence. Washington State University is an equal opportunity/affirmative action educator and employer. Members of ethnic minorities, women, Vietnam-era or disabled veterans, persons of disability and/or persons between the ages of 40-70 are encouraged to apply. (NW4391)A

INSECT BIOLOGIST

The Department of Entomology, University of Illinois at Urbana-Champaign, is seeking an Assistant Professor (Tenure Track), whose major interests are in insect biology and whose research program is concerned with molecular neurobiology, cell biology (structural or developmental), or genome analysis (including populations). PhD. required.

Postdoctoral experience or other evidence of significant scientific accomplishment must be demonstrated. Teaching responsibilities will emphasize insect physiology

Salary range is competitive, Starting date is August 1990.

To receive full consideration, application must be received by December 31, 1989. Send *curriculum vitae*, statement of research plans and names of three references to:

Dr Stanley Friedman
Chair, Search Committee
Department of Entomology
University of Illinois, 320 Morrill Hall
505 S. Goodwin Avenue, Urbana, Illinois 61801
Telephone (217) 333-8922 Fax (217) 244-1244

The University of Illinois is an Affirmative Action/Equal Opportunity Employer (NW4367)A

AUSTRALIA

MOLECULAR GENETICIST

There is a vacancy for a molecular geneticist to become involved in an ongoing program of research into fragile sites on human chromosomes and the detailed physical mapping of chromosomes A PhD degree and, preferably, some years experience in eukaryote molecular biology are required

Salary will be within the range A$26,617 - $40,100 per annum. The position is initially funded until the end of 1991

Further information can be obtained from

Dr G.R. Sutherland, Cytogenetics Unit, Adelaide Children's Hospital, North Adelaide SA 5006, Australia.
Telephone: International + (619) 267 7284

UNIVERSITY OF KEELE
(Environmental Research Unit)
and
WOLVERHAMPTON POLYTECHNIC
(School of Applied Sciences)

NERC POST-DOCTORAL RESEARCH ASSISTANT IN PALYNOLOGY

Applications are invited from experienced pollen analysts for an eight-month research assistantship, based at Keele, to investigate Quaternary inter-stadial environments in North Wales. Palynological experienced with British Pleistocene or Continental Quaternary sediments would be an advantage Principal investigations are Dr K. Addison (Wolverhampton) and Martin Edge, collaborating with Dr F M. Chambers (Keele).

Salary will be at an appropriate point on the Research IA (£10,458 to £11,088 p.a.) or IB (£9,816 to £11,088 p.a.) Scales, pro rata.

Application forms and further particulars from **the Registrar, University of Keele, Keele, Staffordshire, ST5 5BG (Tel: (0782) 621111 Ext. 3008).**

Closing date: 27 October 1989 (1831)A

The Queen's University of Belfast

POSTDOCTORAL RESEARCH ASSISTANT

School of Biology and Biochemistry

This post, funded by SERC, is available for three years commencing as soon as possible to investigate meiosis associated proteins in male grasshoppers. Duties will include the rearing and management of grasshopper stocks Applicants must hold, or be about to obtain, a PhD in Biology or Molecular Biology and should preferably have experience of some of the following techniques: 2 Dimensional electrophoresis, Western blotting, immunofluorescent microscopy, immunogold electron microscopy, animal cell culture and the preparation of monoclonal antibodies. A good understanding of meiosis and/or protein/nucleic acid interaction would be beneficial.

Salary: £10,458 per annum.

Applicants, quoting ref. 89/B2, should submit a curriculum vitae, including the names and addresses of two referees to the **Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN.** Closing date: 27 October 1989.

The University is an Equal Opportunity Employer. (1833)A

UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY

LECTURESHIP IN ORGANIC CHEMISTRY

Applications are invited for a Lectureship in Chemistry from candidates with research interests and achievements in any area of organic synthesis/methodology, tenable from October, 1990. In addition to promoting an active research group, the appointee will be expected to give lectures, tutorials, and conduct laboratory teaching in various aspects of Organic Chemistry.

The initial appointment is expected to be on the Lecturer Grade A Scale (£10,458-£15372), but for more experienced applicants may exceptionally be on the Lecturer Grade B Scale (£16,014-£20,469).

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE** (Tel. 091-374-2265), to whom applications (3 copies, including full C.V. and the names of three referees) should be sent not later than *Friday, 1st December, 1989.* (Please quote Ref. CH3.) (1814)A

DEPARTMENT OF HUMAN ANATOMY
(University of Oxford)

POST DOCTORAL RESEARCH ASSISTANT

— Grade RS1A
Salary £10,458-£16,66[illegible]

A post-doctoral position is available from 1 January 1990 in a busy research group studying normal and abnormal visual pathways within the central nervous system. Relevant experience and knowledge of immunohistochemical techniques is essential The successful candidate would be expected to study thalamo-cortical pathways

The position is funded by a programme grant from the Wellcome Trust until December 1994.

Written applications, including a full c.v and the names and addresses of two referees, should be sent to **Professor R.W. Guillery FRS, Department of Human Anatomy, South Parks Road, Oxford OX1 3QX.** The closing date for applications is 30th October 1989.

The University is an Equal Opportunity Employer (1841)A

SWISS FEDERAL INSTITUTE OF TECHNOLOGY LAUSANNE
(ECOLE POLYTECHNIQUE FEDERALE DE LAUSANNE)
announces several openings for position of

FULL PROFESSOR IN EXPERIMENTAL PHYSICS

n the following domains:

- **Physics of electronic materials**
- **Physics of semicrystalline solids**
- **Surface physics/Surface science**
- **Physics for biomedical engineering**

Teaching is given in French.

Applications deadline: November 30th, 1989

The successful candidates are expected to start their activities in summer–fall 1990.

For more information, and application, write to:

Secrétariat général de l'Ecole Polytechnique Fédérale de Lausanne,
CE-Ecublens, CH 1015 Lausanne — Switzerland

An der Medizinischen Fakultat der Albert-Ludwigs-Universität Freiburg/Br. ist im Institut für Medizinische Mikrobiologie &
Hygiene/Abteilung Virologie (Prof. Dr. Otto Haller) eine

Profissur C3 für Molekulare Virologie

neu zu besetzen. Der Stelleninhaber soil das Fach in Forschung und Lehre vertreten und einen der drei am Ort vorgesehenen wissen-schaftlichen Schwerpunkta (Molekulare Virologie) leiten. Einstel-lungsvoraussetzungen sind Habilitation oder gleichwertige wissen-schaftliche Leistungen auf dem Gebiet der virologischen Grundla-genforschung. Der Bewerber soll solide Kenntnisse der Molekular-und Zellbiologie besitzen und in der Lage sein, Fragen der Virus-Wirtszellinteraktion, der viralen Pathogenese und der molekularen Mechanismen der Virusabwehr zu bearbeiten. Eine Beteiligung an den Aufgaben der mittelbaren Krankenversorgung unter Berücksichtigung der besonderen Fachkenntnisse wird erwartet. Bewerbungen mit den üblichen Unterlagen und 5 ausgewahlten Veröf-fentlichungen sind bis spätestens 20. November 1989 an den Dekan der Medizinischen Fakultät der Universität Freiburg, Postfach, D-7800 Freiburg/Br. zu richten.

(W6580)A

University of Glasgow
Department of Veterinary Pathology
Postdoctoral Research Assistant

We have a vacancy for a postdoctoral Research Assistant in our Bacteriology subdepartment. The successful applicant will continue a study of the role of egg transmitted immunity to salmonellae in the protection of chicks against systemic infection and intestinal colonisation with *S. enteritidis* and *S. typhimurium*. He/she will be expected to work mostly with SPF chickens and to purify protein and LPS antigens from salmonellae. A substantial portion of the study will be concerned with the antibody response of the hen to salmonellae, and the transfer of specific antibody through the egg to the chick and the mechanisms by which protection is produced.

A veterinary degree is not essential for this post which is funded by the AFRC for 3 years. Salary will be on the 1A Scale for Research and Analogous Staff (£10,458 to £16665, depending on age and experience).

Applications, together with a curriculum vitae and the names and addresses of two referees should be sent to **Dr. D.J. Taylor, Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden, Glasgow, G61 1QH.** (1835)A

HUMAN GENOME INFORMATICS
Section Leader

Los Alamos National Laboratory has a broad research and development effort in the Human Genome Program, including development of new DNA sequencing technologies, generation of physical (ordered-clone) maps of human chromosomes and development of a Human Genome Information Resource to facilitate management and analysis of data generated by the Program.

The section leader will supervise a multidisciplinary team to develop systems for image analysis of electrophoresis gels; design and develop a database of physical mapping information for Laboratory and national use; develop software that provides access to the above as well as links to genetic map, sequence and other related databases; determine project hardware needs and oversee procurement; collaborate with corporate partners to facilitate transfer of technology to the private sector; and interact productively with other database projects at Los Alamos. The successful candidate is expected to conduct research on topics such as image analysis, database management systems, knowledge representation in molecular biology or algorithms for physical map construction. Will have opportunities to assist in planning the national Human Genome Program.

It is expected that the successful candidate will have research experience in computational science as applied to molecular biology as well as experience in software and systems design, for example communication networks, complex databases or user interfaces. Experience with graphics and database management systems desirable. Record of innovation and project completion required. Excellent leadership and oral/written communication skills are essential. A PhD in computer science or molecular biology/genetics or the equivalent combination of education and experience is required.

As a leading R&D institution, we provide an attractive salary/benefits package and a challenging work environment. Interested candidates should forward a resume to Ray Archuleta (MS P280), Personnel Services Division 90716-EH, Los Alamos National Laboratory, Los Alamos, NM 87545, with a copy to George Bell (MS K710), Theoretical Division, from whom additional technical information can be obtained at 505-667-7510.

Affirmative Action/Equal Opportunity Employer.

University of California (NW4383)A
Los Alamos

UNIVERSITY OF LIVERPOOL
Department of Biochemistry

Postdoctoral Senior Research Assistant

Initial salary on the scale £10,458–£12,381 per annum.

A three year post in the Gene Expression Group to study the structure, expression and function of recently isolated genes from *Xenopus* that contain a paired box and probably also a homeobox. The paired box is one of a number of conserved sequences that are present in the genes controlling animal development and, like the homeobox, may confer DNA binding. During the project nucleic acid and antibody probes will be made and used to determine the pattern of gene expression at the RNA and protein level. Attempts to understand the function of the genes by disrupting expression will also be made: Informal enquiries to **Dr. P.C. Turner (051-794 4367). Quote ref: RV/518/N.**

Departments of Biochemistry and Veterinary Clinical Science

Postdoctoral Senior Research Assistant

Initial salary on the scale £10,458–£12,381 per annum.

To analyse the molecular biology of feline calicivirus with the aim of developing a better strain typing system and vaccine. The viral genome has already been cloned and the project would begin by identifying the gene organization using sequence information combined with detecting expression of fusion proteins using existing and new antibodies. Antigenic variation of different strains will be examined to see if specific oligonucleotides can be designed which will enable rapid strain identification. Informal enquiries to **Dr. P. C. Turner (051-794 4367) or Dr. R.M. Gaskell (051-794 6115).** Quote ref: RV/519/N.

Applications, by c.v. with the names of three referees, should be received not later than 27th October 1989, by **The Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool, L69 3EX,** from whom further particulars may be obtained.

An Equal Opportunity Employer (1804)A

FACULTY POSITION
VECTOR TRANSMISSION
DEPARTMENT OF PLANT PATHOLOGY
UNIVERSITY OF CALIFORNIA, RIVERSIDE

Applications are invited for an 11-month tenure-track position at the Assistant Professor level. Appointee is to develop an independent program on vectored diseases and establish basic knowledge about pathogen-vector relationships. Opportunities exist for interaction with departmental programs on citrus, ornamental, field and vegetable crops. Some of these programs include virology and virus diseases, molecular genetics of plant pathogens and the physiology and pathogen host interactions Teaching responsibilities include participation in team-taught plant pathology graduate courses, the opportunity to develop a graduate level course on virus-vector relationship and direction of graduate student research. Ph.D. required with experience in plant pathology and pathogen-vector relationships and an interest in working with viruses, fastidious procaryotes or other vectored plant pathogens. A curriculum vitae, complete transcripts, a statement of research interests, and three confidential letters of recommendation should be sent by January 1, 1990 to **Dr. David J. Gumpf, Search Committee Chairman, Department of Plant Pathology, University of California, Riverside, CA 92521.**

Women and minority candidates are encouraged to apply.

Equal Opportunity/Affirmative Action Employer (NW4387)A

UNIVERSITY OF KEELE
DEPARTMENT OF PHYSICS
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a postdoctoral research assistantship to work with Professor M.J. Gillan on the ab initio calculation of the properties of solids. Applicants should have, or expect to receive, a PhD in an appropriate area. The calculation of solid-state structure and energetics using electronic-structure methods is an exciting and rapidly-developing field. The work will focus on the ab initio study of defects in metals and insulators using novel techniques recently proposed by Car and Parrinello, and is expected to lead to major advances.

The position is funded by the SERC and is tenable for up to two years with a salary on the RA(1A) scale. Application forms and further details can be obtained from the **Registrar, University of Keele, Keele, Staffs. ST5 5BG. (Tel: 0782-621111, ext. 3008).** Informal enquiries to Professor M. Gillan (Tel: 0782-621111, ext 3911) are welcomed. The closing date: 17 November 1989. (1830)A

PUBLIC HEALTH LABORATORY SERVICE

CENTRAL PUBLIC HEALTH LABORATORY
FOOD HYGIENE LABORATORY

BASIC/SENIOR MICROBIOLOGIST

To assist in the provision of a national and international reference service for food poisoning bacteria and to undertake associated research. You should hold an honours degree in microbiology, and a higher degree would be an advantage. Preference will be given to those with laboratory experience of serological typing and immunoassay techniques.

Further details from Dr R J G bert on extension 4116.

Salary: Senior — £12,535 £16,151 pa (inclusive). Basic £9,012 to £11,830 pa (inclusive).

The level of appointment dependent on qualifications a experience.

For a job description and app cation form contact:— CPHL Pe sonnel, 61 Colindale Avenu London, NW9 5HT, or ring 0 200 4400, ext 3890.

Please quote ref: FHL/19.

Closing date: 3 November 198 (1839)A

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES

RESEARCH ASSISTANT

A good honours graduate is required to start work immediately on the control of DNA replication in Extracts prepared from *Xenopus* eggs The project will involve a range of immunological and microscopic techniques including immunoblotting, confocal microscopy and immuno E.M In addition, some molecular biology techiques will be employed. Expertise in any of the above would be an advantage, although training will be provided. The successful applicant will be encouraged to apply for a higher degree.

The post will be for 3 years and salary will be in the range £9,816 – £11,736 per annum dependent on qualifications and experience

Applications with C V. (2 copies) and the names of 2 referees to the **Personnel Office, The University, Dundee DD1 4HN. Please quote Ref: EST/440/89/N.**

Closing Date: 2 November 1989. (1810)A

UNIVERSITY OF SOUTHAMPTON
Department of Physics

Postdoctoral appointment in Magnetism and Superconductivity

Applications are invited for a postdoctoral research assistant to work on the magnetic characterisation of disordered magnets, heavy fermion compounds and high temperature superconductors. The post involves the operation of SQUID and conventional magnetometers and the use of neutron scattering techniques.

Applicants should have a background in experimental solid state physics. The post is funded for 2 years by the SERC with the possibility of a further 2 years. Initial salary in the range of £10,458-£12,381 according to age and experience.

Applications with CV and names to two referees should be sent to **Dr. P.A.J. de Groot, Physics Department, Southampton University, Southampton SO9 5NH,** to arrive by 12th November, 1989. Please quote reference no 91/JAD/nvs. (1820)A

UNIVERSITY OF CAMBRIDGE

PROFESSORSHIP OF VETERINARY CLINICAL STUDIES

Applications invited for the above Chair tenable from 1 October 1990 Present pensionable stipend £29,732.

Further information from the **Secretary General of the Faculties, General Board Office, The Old Schools, Cambridge, CB2 1TT,** to whom applications (10 copies), marked 'confidential', should be sent with names of two referees by 17 November 1989.

The University follows an equal opportunities policy. (1807)A

University of Newcastle upon Tyne
Human Metabolism Research Centre

Research Associate

A post doctoral Research Associate is required to work on insulin action in human skeletal muscle A biochemical background and practical laboratory experience are necessary Salary will be at an appropriate point on the IA research staff scale (10,458–£16,665 per annum).

For further details write to **Dr Roy Taylor, Department of Medicine, Medical School, Framlington Place, Newcastle upon Tyne NE2 4HH.** Closing date for applications is 27th October 1989. (1852)A

FELLOWSHIPS

RAMSAY MEMORIAL FELLOWSHIP FOR CHEMICAL RESEARCH

The Trustees will consider in February 1990 applications for a General (British) Fellowship, normally tenable in the United Kingdom for two years, for candidates with experience of post-doctoral research It is desirable that the successful applicant would not have done more than two years post-doctoral work and would be not more than 28 years of age on taking up the appointment. The value of the Fellowship will normally be parallel with the lower part of the Lecturer scale for British universities, plus an expenses grant of up to £100 per annum; it may be superannuable. The person elected will normally be required to take up the Fellowship on or about 1 October 1990. Particulars from the **Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College London, Gower Street, London WC1E 6BT.** Completed application forms must be received by 1 December 1989. *Equal Opportunities Employer.* (1797)E

Merrell-Dow/Université Louis Pasteur Fellowship of the Académie des Sciences

A post-doctoral fellowship will be available at Université Louis Pasteur, Strasbourg, starting from the end of 1989 early 1990, for work on applications of Nuclear Magnetic Resonance to the determination of structure and dynamics of petides, proteins and DNA sequences involved in mutagenesis. Available spectrometer fields: 200, 300, 400 and 500 Mllz. Computational, modelling and graphic display capabilities. The research programme is developed in close collaboration with molecular biologists.

The successful candidate will preferentially have obtained very recently a Ph.D in Organic Chemistry, in Biochemistry or in Biophysics, if possible with some experience in high field NMR. His appointment will be for one year, exceptionally renewable, at the rate of 10,000 FFR/month. Health insurance and help for housing provided. No travel funds.

The Merrell-Dow Fellowship was funded to promote the international relations of Université Louis Pasteur, in particular with the USA. The beneficiary and his laboratory are completely free to define the problem chosen and to publish the results obtained.

Candidates are requested to send a detailed C.V. and the names of two referees to **"Prof. J.F. LEFEVRE, I.B.M.C., 15 rue René Descartes, 67084 Strasbourg Cedex, France"**, before December 1st. (W6605)E

Klinikum der Universität Heidelberg

NMR-Spektroskopiker(in) gesucht

Im Rahmen des Kolonkarzinom-Projektes 1990-91 des Tumorzentrums Heidelberg/Mannheim sucht die Abt. Zentrale Spektroskopie (Leiter: Dr. W.E. Hull) des Deutschen Krebsforschungszentrums, Heidelberg, einen erfahrenen NMR-Spektroskopiker(in) (promovierter Wissenschaftler(in)) für

a) methodische/technische Entwicklung im Bereich Hockfeld-NMR-Spektroskopie/-Bildgebung in vitro und in vivo (Bruker AM-500 und AM-300 SWB Spektrometer)

und

b) entsprechende wiss. Mitarbeit bei kooperativen Forschungsvorhaben im Bereich der Fluorpyrimidin Chemotherapie (Zellkultur und Tiermodell) und ihrer klinischen Anwendung.

Die Stelle ist fur den Zeitraum 01.01.1990 bis 31.12.1991 zu besetzen. Die Vergütung erfolgt nach BAT.

Bewerbungen (C.V. und Publikationsliste) bitten wir bis spätestens 13.11.1989 zu senden an **Dr. W.E. Hull Deutsches Krebsforschungszentrum, Abt. Zentrale Spektroskopie, Im Neuenheimer Feld 280, 6900 Heidelberg.** (W6611)A

FACULTY POSITION

Plant Molecular Biology

The Department of Botany, Iowa State University, invites applications for a tenure-track position of assistant professor. Development of a strong research program in plant molecular biology supported by extramural funds is expected. Teaching responsibilities will include a graduate course in plant molecular biology and participation in undergraduate teaching. Candidates must have a Ph.D. or equivalent. Generous start-up support possible. Successful candidate will join an active program in molecular biology.

Applications must include a curriculum vitae, statements of research interests and teaching philosophy, and reprints of selected publications. Applications and at least three letters of reference should be sent to **Dr. David C. Glonn-Lewin, Chair, Department of Botany, Iowa State University, Ames, IA 50011** by December 15, 1989.

Women, minorities and members of all underrepresented groups are strongly encouraged to apply. *Iowa State University is an Equal Opportunity/Affirmative Action Employer.* (NW4376)A

THE UNIVERSITY OF MELBOURNE

AUSTRALIA

LECTURER (CONTINUING) IN THE SCHOOL OF BOTANY

Following its Review, the School of Botany seeks to appoint a botanist to further strengthen the teaching and research effort in systematics, taxonomy and evolution of higher plants with special reference to the Australian flora. Applicants must have experience in modern approaches to systematics and evolutionary botany combined with interests over the breadth of plant diversity. The applicant will be expected to contribute significantly to the teaching and research programmes of the School. This is a continuing appointment to commence as soon as possible after 1 January 1990.

The salary is in the range: $A31,259-$A40,622 per annum.

Further information about the position is available from Professor J. Pickett-Heaps, Head of Department on (613) 344 5067.

Closing date: 31 October 1989.

Position no: 6060020.

Further printed information regarding details of application procedure and conditions of appointment is available from Ms Mary Petras, Personnel Services on (613) 344 7546.

Written applications should reach The Director, Personnel Services as stated below.

Applications, in duplicate, including names and addresses of at least three referees and quoting the relevant position number should be addressed to The Director, Personnel Services, The University of Melbourne, Parkville, Victoria, 3052, Australia.

An equal opportunity employer. (W6583)A

SANDOZ

Dept. of Preclinical Research, Biotechnology Group,
Sandoz Ltd., Basle

Applications are invited for

POST-DOCTORAL FELLOWSHIP IN MOLECULAR BIOLOGY/ TRANSGENIC TECHNIQUES

Appointed candidates will participate in the establishment and analysis of transgenic animal models for biomedical research. In particular they will be in charge of the design and construction of sequences suitable to induce homologous recombination when introduced into embryonic stem cells (gene targeting).

Applicants should have experience in molecular biology and cell culture techniques. Equally important is a strong commitment to the research described.

Applications, including the names of two referees, should be sent to:

Sandoz Ltd.,
Personnel Department,
Ref. 9806
attention Mr. R. Zbinden
CH–4002 Basle, Switzerland

SANDOZ

(W6568)E

THE OPEN UNIVERSITY
Faculty of Science
Research Fellowship in Earth Sciences (Petrogenesis Research Group)

Applications are invited for a two-year post-doctoral Research Fellowship in Geochemistry available from 1st January 1990. Candidates should have a strong commitment to develop innovative analytical and computer software techniques and will be expected to make a positive contribution in this area. Present research interests in the department include: (i) Planetary sciences, including cosmo-chemistry, remote sensing, and physical volcanology; (ii) Terrestrial magmatism and tectonics with emphasis on the generation and remobilisation of continental lithosphere; (iii) Sedimentology and palaeontology, where most work involves basin analysis and the palaeobiology of Mesozoic Tertiary fauna. Applicants are invited to submit a brief outline of the research programme they would like to undertake if successful.

The appointment will be for an initial period of two years (continuation negotiable).

Applicants should possess a good first degree in geology and a PhD in geochemistry. Salary will be on the 1A Scale for Research and Analogous Staff: £10458-£16665 p.a. depending on age and experience.

Application forms and further particulars are available from **Ann Hall (4727/2), Faculty of Science, The Open University, Walton Hall, Milton Keynes, MK7 6AA,** or telephone Milton Keynes (0908) 655938: there is a 24 hour answering service on 653868.

Closing date for applications: 31st October 1989

Equal Opportunity is University Policy (1824)E

POSTDOCTORAL FELLOWSHIP

involving instrumentation and methods development related to increasing sensitivity of protein microsequencing. Background in biochemistry or protein chemistry preferred. Experience in protein sequencing, HPLC, and electrophoresis desirable. Send curriculum vitae and three letters of reference to: **Dr. Leroy Hood, California Institute of Technology, Division of Biology 147-75, Pasadena, CA 91125.** *EOE/AA* (NW4354)E

NOTTINGHAM UNIVERSITY
DEPARTMENT OF CHEMISTRY

POSTDOCTORAL RESEARCH FELLOWSHIP IN SYNTHETIC ORGANIC CHEMISTRY

Applications are invited for a Two year Postdoctoral Research Fellowship, funded by the British Technology Group, to study the design and synthesis of novel ACAT inhibitors in collaboration with Dr D.W. Knight.

Applicants should have a general background of synthetic organic chemistry and have at least completed the preparation of their Ph.D. thesis.

The appointment is available from October, 1989 and is for one year in the first instance. The salary is on the RAIA scale, commencing at £11,088 per annum.

Applications, which should include a curriculum vitae together with the names of two referees, should be forwarded to **Dr. D.W. Knight, Chemistry Department, University Park, Nottingham, NG7 2RD** as soon as possible. (1800)E

UNIVERSITY OF NOTTINGHAM

POSTDOCTORAL FELLOWSHIP IN BIODEGRADABLE COLLOIDS FOR DRUG DELIVERY

Applications are invited for a post-doctorate fellowship funded under a 3 year SERC collaboration award with ICI Pharmaceuticals and Agrochemicals to develop novel biodegradable polymeric colloids for site-specific drug delivery. The research programme will be multi-disciplinary encompassing aspects of colloid synthesis and characterisation through to the determination of the *in vivo* disposition of the colloidal carriers with gamma scintigraphy. The successful applicant, who may be a chemist, polymer scientist, biologist or pharmacist, will join an active research group within well equipped laboratories with an international reputation in drug delivery and will spend a significant period at ICI Research Laboratories. Interested applicants should write with a CV to **Professor S.S. Davis, Department of Pharmaceutical Sciences, University of Nottingham, Nottingham, NG7 2RD (0602-484848 Ext. 3217).**

(1799)E

ASSISTANTSHIPS

UNIVERSITY OF ABERDEEN
AFRC-FUNDED RESEARCH ASSISTANTSHIP
Molecular basis of mechanisms of osmoregulation in enteric bacteria

A research position is available in the laboratory of Dr I R Booth for a period of three years, starting not later than 1 February 1990 and is suitable for a graduate wishing to register for a higher degree. Candidates should have a 2.1 degree (or better) in Microbiology, Genetics or Biochemistry and should be strongly motivated towards a research career. The successful candidate will be expected to undertake several periods (two to three weeks duration) away from Aberdeen to work with collaborative research groups. Starting salary £9,816 per annum.

Further particulars from the Personnel Office (tel 0224 273500). Applications by letter with full CV including the names of three referees to the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX** by 3 November 1989 quoting reference number LW/057. (1812)P

GRANTS & SCHOLARSHIPS

University of Oxford
Scholarship for Medical Training

A scholarship is available for a well-qualified graduate aiming for medical training. The award covers home tuition fees and a generous contribution towards maintenance for the pre-clinical course only. Full details are available from the Graduate Admissions Office, University Offices, Wellington Square, Oxford, OX1 2JD. The latest date for receipt of applications is 31 October 1989. (1843)H

H. Land, ICRF, London
R. Nusse, Netherlands Cancer Institute, Amsterdam

The deadline for applications is **31st January 1990**
The total number of participants will be limited to 250.
Registration fee: **DM 400,-** (includes local transport and meals), reduced rate for graduate students **DM 200,-**
The registration fee does NOT cover the cost of accommodation and should NOT be sent before acceptance to the conference.
Abstracts will be selected for presentation as posters and a small number of abstracts will be selected for oral presentation.
Application and abstract forms can be obtained from
Dr. Thomas Graf, EMBL, Meyerhofstr. 1, 6900 Heidelberg, FRG.
Tel: (6221) 387410; Fax (6221) 387306 (W6588)C

TOOLS FOR A NEW BIOLOGY

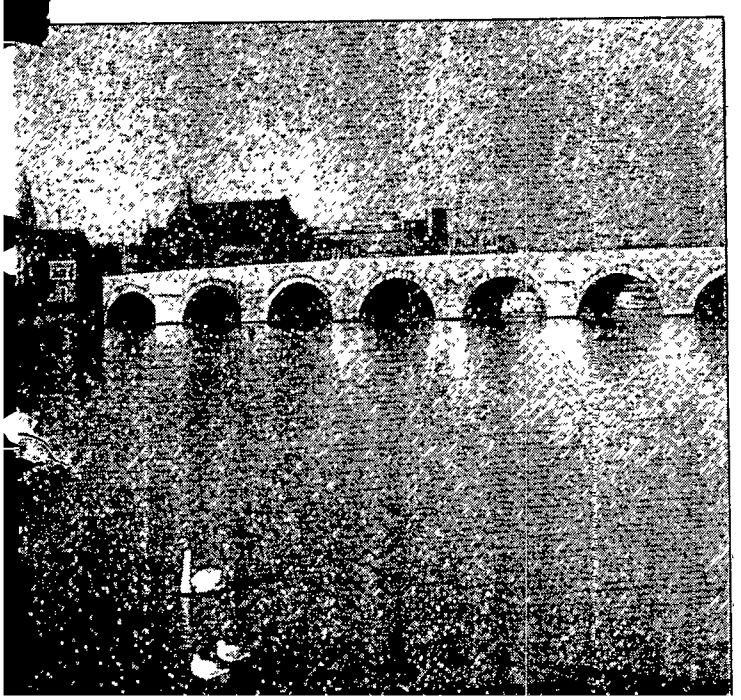
A one-week course focusing on an integrated, multi-disciplinary approach to the development of procedures for the separation, detection, and micro-characterization of complex mixtures of proteins and nucleic acids. Includes the role of novel computer hardware/software in the analysis of biological data Sponsored by the NSF Center for Biotechnology. Director: Leroy Hood. For information contact. **Sue Lewis, Caltech, Div. Biology, 147-75, Pasadena, CA 91125. Phone: (818) 356-8390 or Fax (818) 793-4627.** (NW4364)C

SCA SCIENTIFIC COMPUTING AND AUTOMATION (EUROPE)

nature

Conference and Exhibition, 12–15 June 1990, Maastricht, The Netherlands

ELSEVIER



The 2nd **SCA** conference and exhibition will be held in Maastricht, The Netherlands, an ideal location which takes the meeting into the heart of Europe.

As before, **SCA** is entirely devoted to computing and automation subjects which cross all scientific disciplines; hence the continued theme 'Les Sciences sans Frontières'.

Under the Chairmanship of Dr. Erkii Karjalainen from Helsinki, **SCA** will bring together specialists from a wide range of disciplines with expert knowledge encompassing the following topics:

- **Chemical applications for supercomputers**
- **Sampling strategies and experimental design**
- **Scientific Databases**
- **New Emerging Standards**
- **Dynamic models for catalysis, processes and metabolism**
- **Expert systems and statistical tools for the interpretation of laboratory data**
- **Robotic and discrete automation in the laboratory**
- **Interfacing tools; software and hardware tools**
- **Chemical monitoring - multivariate sensors and biosensors**
- **LIMS and LAN strategies for the laboratory**
- **Workstations for scientists - RISC, parallel and traditional**
- **Scientific applications for neural networks and fractals**
- **Software toolkits for exploratory data analysis and mathematics**
- **Computer graphics and image analysis**
- **Designing molecules by computer**
- **Europe 1992: Implications for standards across borders**
- **Validation and Certification**

(W6589)C

INTERNATIONAL EXHIBITION: An international exhibition will complement the SCA conference - both of which will be held under one roof. The exhibition will be organised by the publishers of *Nature* magazine.

YES, please send me further information about the Scientific Computing and Automation (Europe) Conference/Exhibition.

ARE YOU LOOKING FOR OPPORTUNITY IN RESEARCH?

Research Development Corporation of Japan (JRDC), established in 1961, is a government owned organization which operates under the Science and Technology Agency (STA).

The objective of JRDC is to effectively carry out the development of new technology, engage in the basic research deemed to contribute to the creation of new technology, and to disseminate the outcome of these developments and basic research.

In addition to these activities, JRDC is to undertake the promotion of the International Research Exchange Program, consisting of 1) The International Joint Research Program, 2) The STA Fellowship Program, 3) The Support Programs, and 4) The Research Information Program.

INTERNATIONAL JOINT RESEARCH PROGRAM

1. Purpose

This program shall work toward the following purposes through joint research supported by JRDC and foreign research organizations:

(1) Develop the seeds of innovative science and technology by integrating the advanced research activities of Japan and of other countries concerned; (2) Contribute internationally by fostering broad public dissemination of the knowledge gained from such research; and (3) Promote research exchange between Japan and other countries, thereby promoting science and technology.

2. Outline of the Program

Non-Japanese research organizations wishing to conduct joint research projects with JRDC shall carry out such research with JRDC within the following framework, and shall share, on an equitable basis, personnel and all expenses and costs necessary for the implementation of the research.

(1) Research fields and themes

Research themes are to be sought in basic research fields including new materials, life sciences and electronics. Themes should be directed toward creating new concepts that will become the seeds of innovative science and technology development. These research themes must be those for which consent is obtained from both JRDC and its counterpart.

(2) Framework for a Joint Research Project (Standard model for joint research)

① Term: 5 years (Flexible: 3 to 7 years)

② Budget: ¥ 2 to ¥ 3 billion (approx U.S.$14–21 mil.) [Each side bears ¥ 1 to 1.5 billion]

③ Site:

A research site shall be established at a suitable university or a research institute.

④ Researchers:

Both JRDC and its foreign counterpart concerned may select their respective researchers from academia, industry and government.

i) Research directors: 2 (one from each side)

ii) Researchers: 15 to 20 in total for both countries.

⑤ Patent rights:

The patent rights resulting from the joint research should be jointly owned on an equitable basis.

STA FELLOWSHIP PROGRAM

1. Purpose

The purpose of this program is to promote the international exchange of researchers by providing fellowships to foreign researchers in the science and technology fields (excluding those concerned exclusively with the humanities).

2. Outline of the Program

Fellowship awardees fall into two categories: (1) those recommended by their own governments and (2) those recommended by Japanese host institutes.

(1) Numbers of awardees: 130 for FY 1989 (100 for FY 1988).

(2) Qualifications:

① Possession of a doctoral degree in a scientific or engineering field, or an equivalent qualification.

② Age under 35, in principle.

③ Having sufficient language ability to be able to pursue research in Japan. Japanese ability is preferable, but in most cases English ability is sufficient. With the host institute's agreement, other languages may also suffice.

3. Tenure and field of research:

Tenure is between 6 months and 2 years, to be decided through negotiation between the candidate and the host institute.

The field of research is also decided through negotiation between the candidate and the host institute. The results of research work produced during the tenure will be subject to the regulations of the host institute.

4. Fellowship awards:

The following items will be provided to the Fellowship awardees as tax-free allowances.

① Round-trip airline ticket (economy class).

② Living allowance: ¥ 270,000 per month, (approx U.S.$2,000).

③ Family allowance: ¥ 50,000 per month (approx U.S.$370).

④ Housing: ¥ 100,000 maximum per month (approx. U.S.$740) may be paid as housing allowance; any shortfall is to be borne by the awardee.

⑤ Relocation allowance for moving from overseas to Japan: ¥ 200,000 (approx. U.S.$1,500).

⑥ Travel allowance (in Japan for business trips regarding research activities): ¥ 100,000 maximum per year (approx. U.S.$740).

5. Host Institutes

Host institutes comprise national laboratories (excluding universities and laboratories affiliated with universities), public (semi-government) corporations, and non-profit organizations.

JRDC is to undertake the implementation of STA Fellowship Program: Japan International Science and Technology Exchange center (JISTEC) is responsible from the receipt of the application from candidates and liaising with them.

SUPPORT PROGRAMS

In order to help foreign researchers, who are engaging in research or exchanging information at Japanese research institutes, and their families to make a smooth transition to research and enjoy their everyday life, JRDC is to promote support programs such as assistance to find houses, supply of information on living in Japan, counselling for daily life and Japanese language lessons.

RESEARCH INFORMATION PROGRAM

For foreign research institutes and researchers who are seeking opportunities for research exchange with Japanese counterparts, information focused on Japanese research activities will be provided.

TWO FORTHCOMING INTERNATIONAL CONFERENCES FROM IBC TECHNICAL SERVICES LTD.

NEW DRUG STRATEGIES IN THE PREVENTION AND TREATMENT OF STROKE

24th/25th January 1990 – London

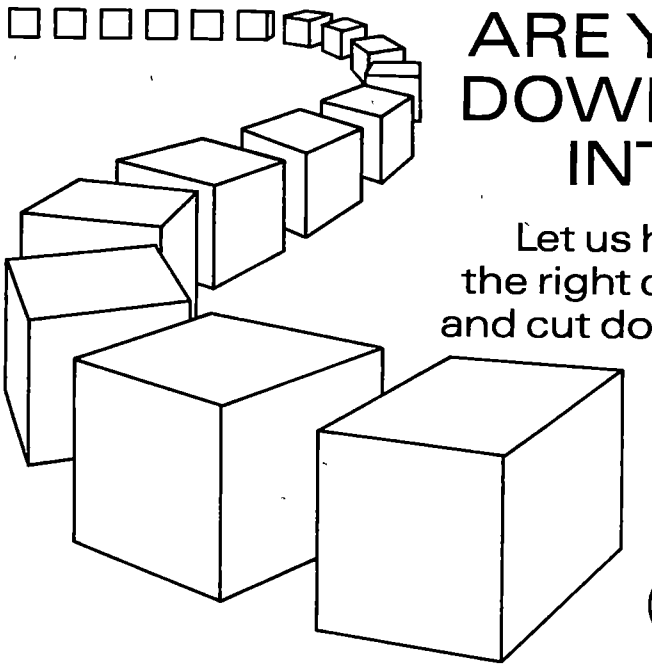
This conference will examine drug strategies that have been tried in the past, and novel pharmacological approaches currently under study, in both the prevention and treatment of acute stroke. Experts in the field will discuss the latest developments, reviewing results from large clinical studies and examining the progress that is being made on the experimental front.

Chairmen and Speakers: **K. Asplund** University of Umea, Sweden; **J.M. Bamford** St James's University Hospital, Leeds, UK; **M.G. Bousser** Hopital de la Salpetriere, Paris, France; **F. Clifford Rose** Charing Cross & Westminster Medical School, UK; **R.A. Fishman** University of California, San Francisco, USA; **E.D. Hall** The Upjohn Company, USA; **M.J.G. Harrison** University College and Middlesex School of Medicine, UK; **J.W. Norris** University of Toronto, Canada; **E.B. Ringelstein** University Hospital Aachen, West Germany; **P. Sandercock** Western General Hospital, Edinburgh, UK; **B. Scatton** LERS, France; **T.J. Steiner** Charing Cross Hospital, UK; **J.P.H. Wade** Charing Cross Hospital, UK; **R. Wise** Charing Cross Hospital, UK; **F.M. Yatsu** University of Texas Medical School at Houston, USA.

AIRWAY HYPERREACTIVITY
Is It Really Important for Asthma?

26th/27th February 1990 – London

Asthma therapy is increasingly being directed to the earlier alleviation of airway hyperreactivity by the treatment of the underlying inflammation using prophylactic and anti-inflammatory drugs. This meeting will review the preclinical and clinical developments in this exciting new field.



Chairmen: **P.J. Barnes** National Heart & Lung Institute, UK; **J. Morley** Sandoz AG, Switzerland;

Speakers: **J.C. Chabala** Merck Sharp & Dohme Research Laboratories, USA; **C. De Vos** UCB Pharmaceutical Sector, Belgium; **M.F. Fitzgerald** Bayer UK Ltd; **P.J. Gardiner** Bayer UK Ltd; **L.G. Garland** The Wellcome Research Laboratories, UK; **S.T. Holgate** Southampton General Hospital, UK; **T. Jones** Merck Frosst Centre for Therapeutic Research, Canada; **R. Lundgren** University Hospital Umea, Sweden; **H.W. Mitchell** University of Western Australia; **C.P. Page** King's College London, UK; **R.R. Schellenberg** St. Paul's Hospital, Vancouver, Canada; **A.E. Tattersfield** City Hospital, Birmingham, UK; **C.D. Wegner** Boehringer Ingelheim Pharmaceuticals Inc., USA; **J.G. Widdicombe** St. George's Hospital Medical School, UK; **A.J. Woolcock** Royal Prince Alfred Hospital, Sydney,. Australia.

SEMINARS & SYMPOSIA

6TH INTERNATIONAL SYMPOSIUM ON THE GENETICS OF INDUSTRIAL MICROORGANISMS GIM 90

Strasbourg, France - 12-18 August 1990

Scientific Programme : Genetic instability ; Heterologous expression ; Secretion ; Extrachromosomal elements, Transposons ; Metabolic pathways manipulation ; Corynebacteria, Production of aminoacids ; Streptomycetes, Antibiotics, Resistance mechanisms ; Lactic acid bacteria ; Industrial yeasts ; Filamentous Fungi ; Methylotrophs, Methanogens ; Genetics of Bacillus ; Clostridia ; Plant-bacterial interactions ; Alcoholic and malolactic fermentations, Aroma ; Biomass degradation ; Toxins of microorganisms ; Bioconversions.
Workshop on : Large-scale industrial cultivation of recombinant microorganisms.

Language : English.

Second Circular : The second circular will be published in October 1989 and will contain the call for papers, instructions for submitting abstracts, symposium programme, registration and accommodation information, social events, tours.

Symposium Secretariat :

AWARDS

The Drs C. and F. Damuth Swiss Medical Research Foundation announces its ninth annual International Award of SFrs 15,000 for young investigators in the Neurosciences

For the 1990 Award, applications are invited from scientists working in the field of

THE ORGANIZATION OF MOTOR SYSTEMS

Candidates from all nationalities, not older than 35 years, are requested to submit (i) their CV including a list of publications, (ii) a résumé of current and projected work (a brief heading followed by two or three typewritten pages), and (iii) reprints of their three most important articles. Also, they are asked to arrange for two referees acquainted with their work to send letters of support directly to the address below.

The jury consists of Professors G. Baumgartner and A Borbèly (Zurich), J. J. Dreifuss (Geneva), J. G. Nicholls (Basle) and H. Van der Loos (Lausanne).

The 1990 Award will be presented at the occasion of the yearly meeting of the Swiss Chapter of the International Brain Reserch Organization to be held January 20, 1990, in Bern, Switzerland.

Applications should be received on or before November 30, 1989, by **Professor H. Van de Loos, Institute of Anatomy, University of Lausanne, Ru de Bugnon 9, 1005 Lausanne, Switzerland.**

CONGRESS

Utilization of Solar Energy

Necessity and Chance

Congress and Exhibition

(Conference language is German)

November 2 and 3, 1989

„Kulturzentrum"

4690 Herne / Federal Republic of Germany

This congress opens up the opportunity to obtain information to initiate a dialogue on new methods of production and utilization of solar energy, on the part that solar energy already plays and could soon play in different regions of the world.

The present state of technology and perspectives of research, development and application will be the topics of this meeting. We will be pleased to answer all your questions relating to the congress and to the Wissenschaftszentrum Nordrhein-Westfalen itself.

Wissenschaftszentrum Nordrhein-Westfalen
Reichsstraße 45, 4000 Dusseldorf 1
Federal Republic of Germany
Telephone: 0211 / 37 05 81, Telefax: 0211 / 37 05 86 (W6574)A

USE THE FAX

to save time and for your added convenience you can contact us by fax.

- for advice on copy, size and cost.
- to inform us of your requirements.
- to send copy for last minute bookings.
- a fax to us will produce speedy results.

HE CARE TO MEET, TO KNOW, TO UNDERSTAND

Ares-Serono Symposia is an independent foundation, created in 1971, to promote scientific research in all disciplines which contribute towards improving human health. This aim is pursued by means of congresses, courses, seminars and specialized studies.

me of the international meetings scheduled for 1990 are:

kines: Basic Principles and cal Applications
nce / March 26-28
tific Organization: A.K. Abbas) and S. Romagnani (I)

rmonal Communicating Events he Testis
e / April 9-10
ntific Organization: M.L. Dufau A) and A. Isidori (I)

roduction, Growth and elopment. V Pan-American gress of Andrology
ulco / April 23-25
tific Organization: A. Negro-Vilar) and G. Perez-Palacios (MEX)

Computers in Endocrinology
Milan / May 7-10
Scientific Organization: V. Guardabasso (I), G. Forti (I) and D. Rodbard (USA)

Major Advances in Human Female Reproduction
Rome / May 10-12
Scientific Organization: E.Y. Adashi (USA) and S. Mancuso (I)

The New Biology of Steroid Hormones
Budapest / September 3-4
Scientific Organization: F. Naftolin (USA)

Endocrinology Under 35
Siena / October 8-10
Scientific Organization: M. Maggi (I)

Plasminogen Activators: from Cloning to Therapy
Florence / October 29-31
Scientific Organization: T. Astrup (DK) and G.G. Neri Serneri (I)

IV Conference on Differentiation Therapy
Yamanashi-ken, Japan / November 4-9
Scientific Organization: G.B. Rossi (I), F. Takaku (J) and S. Waxman (USA)

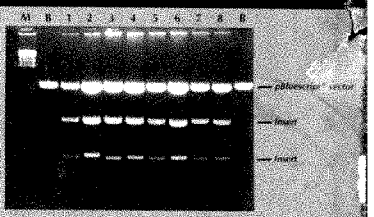
cDNA Synthesis



One Way is the Best Way

- *Undirectional cDNA*
- *Fast: Fewer Reactions Than Most Kits*
- *Efficient: Up To 2.5 x 10^7 Recombinants Per 5 Micrograms of mRNA*
- *Easy: No Enzymatic Methylation Required*
- *Complete: Everything Included (except radiolabel)*
- *Expression Libraries In the Lambda ZAP® II vector*
- *RNase H Method For Extended 5′ Ends*
- *No Linkers*

cDNA with Xho I and EcoR I ends is constructed with the rapid and efficient procedure diagrammed. The procedure is unique in that an **Xho I linker/primer** is used to prime first strand cDNA synthesis. In addition, **dCTP is replaced by 5-methyl-dCTP** in the reaction. Second strand synthesis and EcoR I adaptor additions are performed according to standard protocols. With this procedure the Xho I sites in the cDNA **but not in the linker/primer** are methylated and protected from digestion with Xho I.

A test RNA template is provided in the cDNA synthesis kit. Construction of a test library with this template **in your laboratory** verifies that full length, directional clones that contain the internal Xho I site are obtained with Stratagene's cDNA kit. Shown is an agarose gel analysis of clones obtained from a library constructed with the test RNA template. Eight recombinant clones were excised from the Lambda Zap® II vector in vivo in the pBluescript® plasmid and digested with Xho I and EcoR I; all clones exhibit the expected restriction map, demonstrating that all aspects of the kit performed optimally. M: markers, B: pBluescript®plasmid/EcoR I/Xho I.

Biometra® — Innovations in biomedical

QIAGEN
the fastest way to pure plasmids

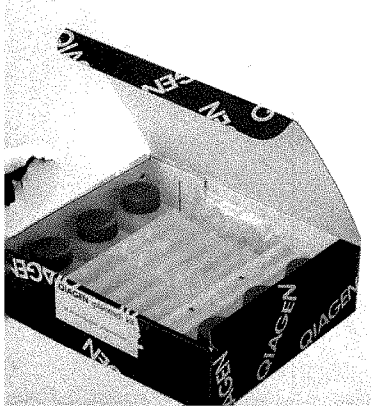
12 high purity plasmid preps in less than an hour ?

Yes, with one of the new QIAGEN >plasmid< kits

matching CsCl purity

with new, short & simple protocols

mini, midi or maxi scale.



QIAGEN Hi purity >plasmid< kits contain our proprietary anion exchange resin QIAGEN in disposable plastic tips, together with all the buffers and solutions required to go from overnight cultures to pure plasmids in 50 minutes (for minipreps, 90 min for maxi preps).

Hi purity kits are available for either 25 Mini- or, 25 Midi or, 10 Maxi preps of DNA of a purity equivalent to CsCl gradients. A fourth kit, QIAscreen, for 100 Mini preps of "screening" quality produces plasmid DNA ideal as a substrate for restriction analysis.

High recoveries
Excellent reproducibility
Non-toxic reagents

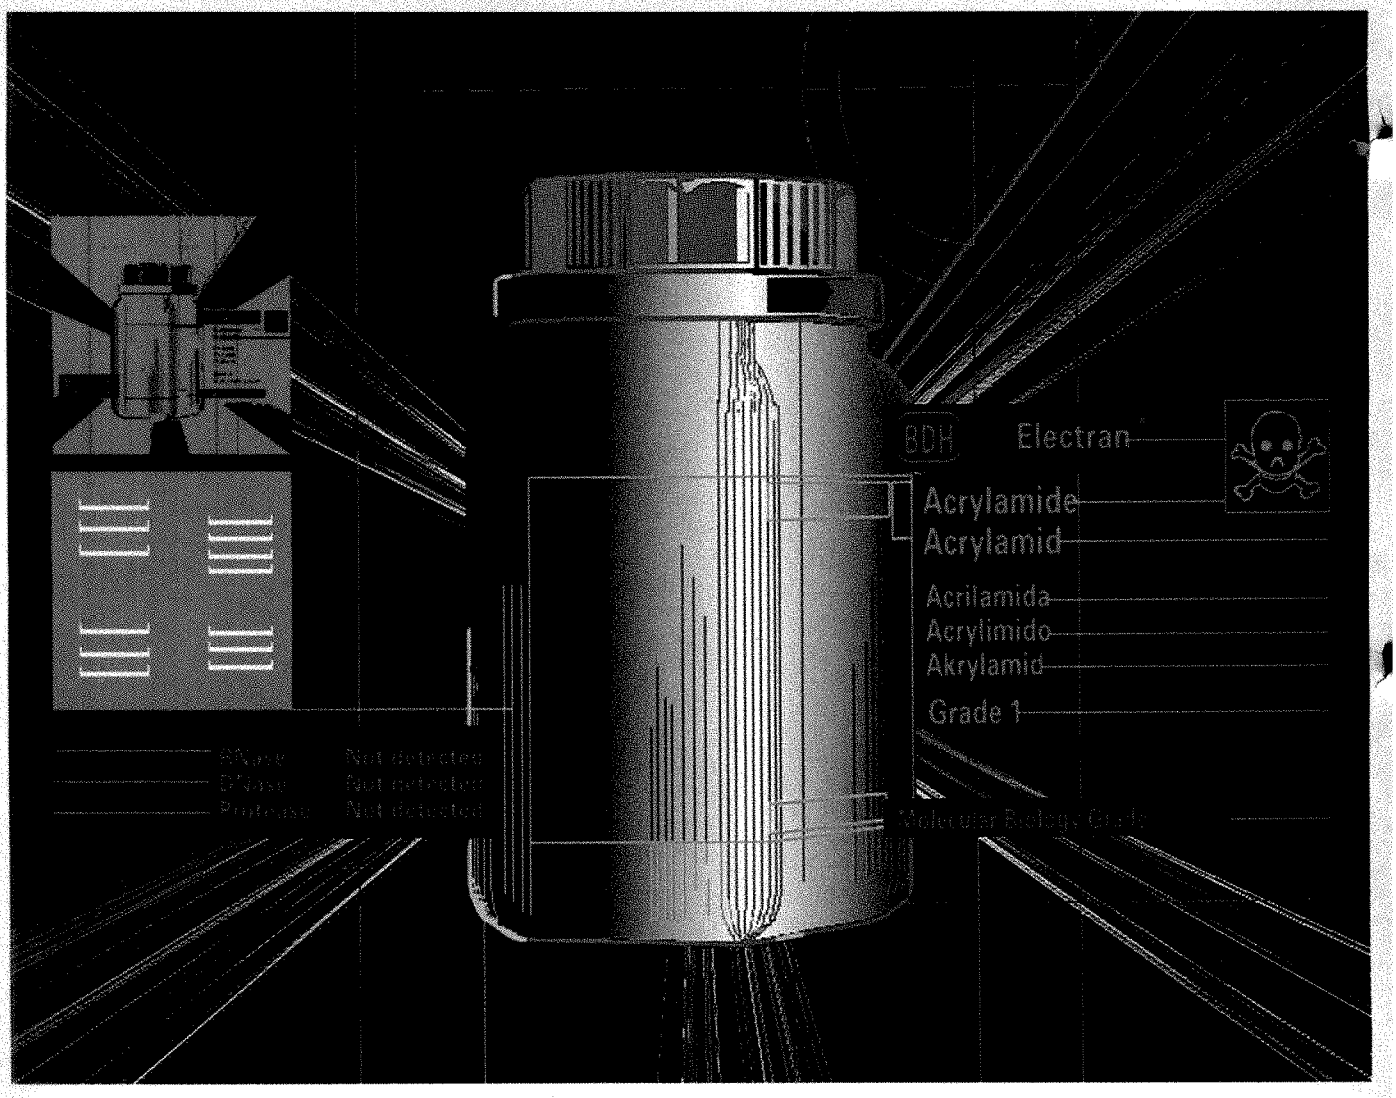
All you need to get started is a

QIAGEN >plasmid< kit

Mini preparation (plasmid DNA)
Hi purity ("for sequencing")

This protocol is designed for 1-3 ml cultures of E.coli.

Procedure



1. *Resuspend the bacterial pellet in 0.3 ml of buffer P1.*
2. *Add 0.3 ml. of buffer P2, incubate at room temp. for 5 min.*
3. *Add 0.3 ml of buffer P3, centrifuge at 4°C for 15 min.*
4. *Apply the supernatant to a QIAGEN-tip 20, pre-equilibrated with 1.0 ml of buffer QB.*
5. *Wash the QIAGEN-tip 20 with 2 x 1.0 ml of buffer QC, and elute the DNA with 0.8 ml of buffer QF.*
6. *Precipitate the DNA with 0.8 volumes of isopropanol.*

BDH ESSENTIAL SCIENCE • BDH ESSENTIAL SCIENCE • BDH ESSENTIAL SCIEN

Everything you want – without the things you don't want.

A NEW RANGE OF REAGENTS, CREATED FOR MOLECULAR BIOLOGISTS.

Why take risks.

By taking care to only use reagents that are free of contaminating DNase, RNase and Protease enzymes you'll have an additional safeguard for your work and its integrity.

Vital results can so easily be compromised and your valuable time and research efforts wasted.

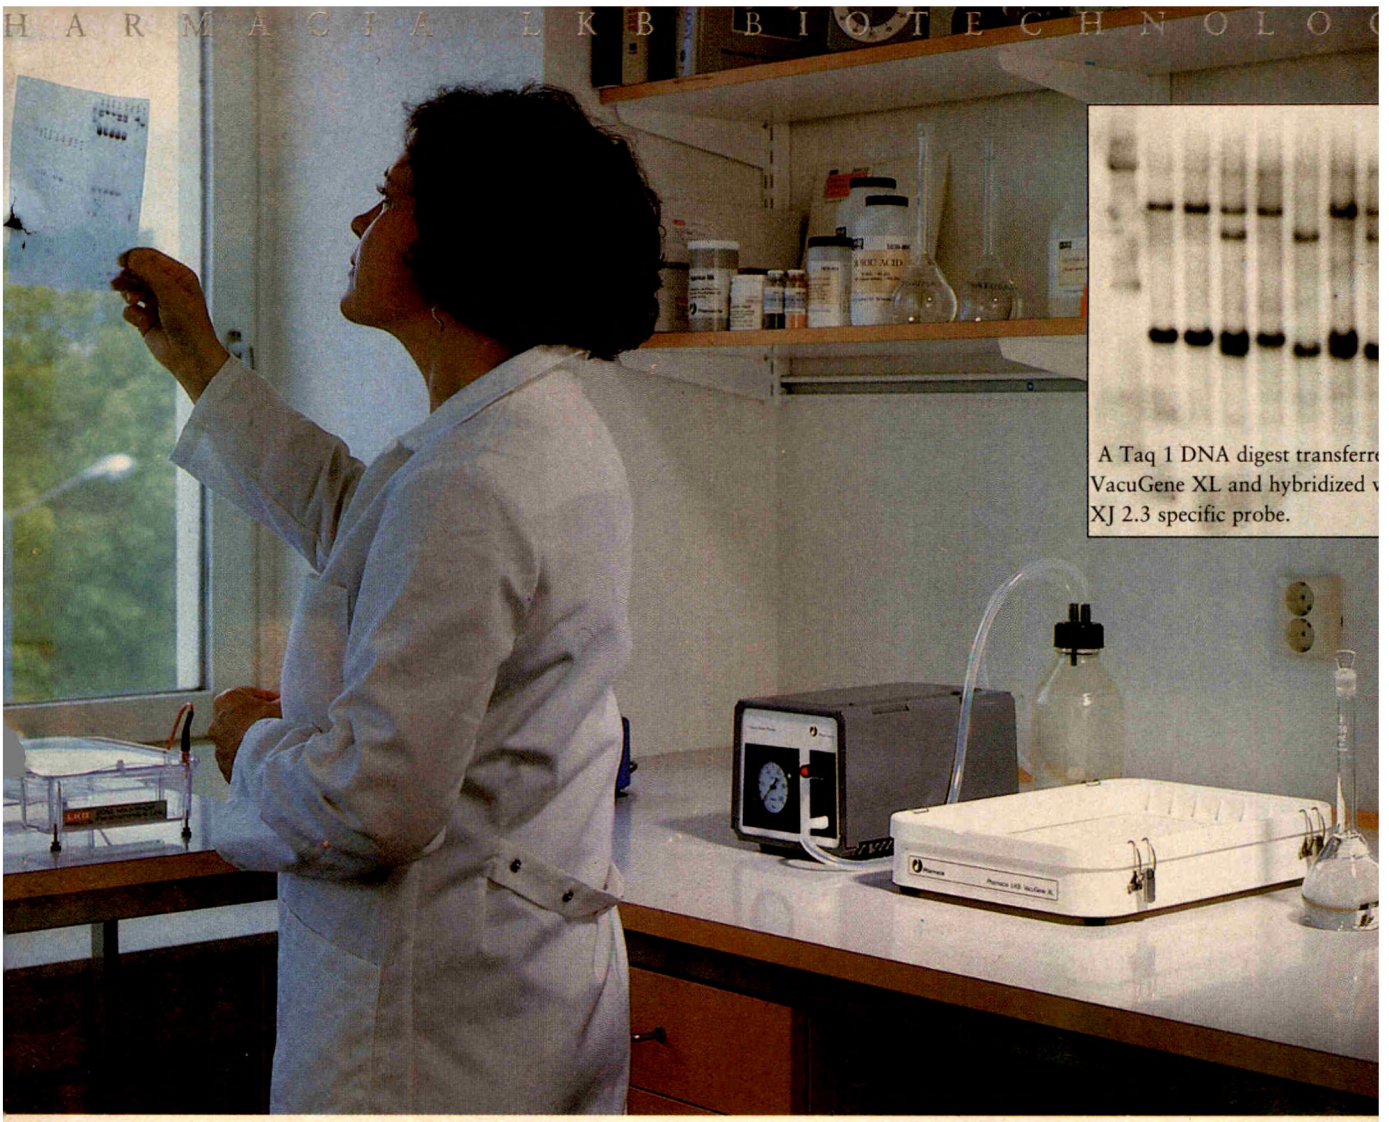
You want results. You want them fast. So think carefully when it comes to selecting reagents; this is an area where you shouldn't be taking chances.

The new range of BDH molecular biology grade reagents meets stringent requirements, assuring freedom from DNase, RNase and Protease enzymes.

Special test methods have been developed in the BDH Research Department at Poole, Dorset.

The high sensitivity of these new BDH tests and our manufacturing skills now make a major contribution to progress through provision of a significant and expanding range of reagents, all of which will be found of value in modern molecular biology work.

New reagents and testing methods are fully outlined for you in a special Product Information Sheet which is available now on request.



So please contact the address below for all the information you need.

Genomic blotting in 2 hours.

Genomic blotting in 2 hours is fast. Very fast. And that means it's also become very easy. Easy enough to let you speed up your studies of inherited diseases, genetic disorders and fingerprinting in forensic laboratories. With results that are accurate and reproducible. Results you can only achieve with a system that's based on precision controlled blotting.

The VacuGene™ XL blotting system is unique. Its low-pressure vacuum pump maintains the exact transfer conditions needed to deliver reproducible results. At speeds that minimize band distortion and diffusion.

VacuGene XL cuts gel pretreatment time from hours to minutes. With depurination, denaturation and neutralization all carried out completely inside the blotting unit. So you won't damage your gels. And safely transfer your DNA or RNA from gels as large as 20 x 30 cm. To give you standard transfers in under one hour. Genomic blots just take a little longer.

VacuGene XL was designed for routine work. So anyone in your laboratory can use it. And bring you blot after blot after blot. With DNA yields approaching 100%. Blotting nucleic acids has never been so easy. So fast. So reproducible. For more information, get in touch with your local Pharmacia LKB office.

We help you manage biomolecules.

19 October 1989

Vol. 341 Issue no. 6243

◀ The martian moon Phobos rises above the horizon, as seen by the Soviet spacecraft Phobos 2. Before succumbing to computer failure, Phobos 2 produced a stream of data on Mars and its moon, the first reports of which appear on pages 581 to 618. See also News and Views page 564.

THIS WEEK

Strange behaviour

The pulsar at the centre of supernova 1987A appears to be stable whilst rotating at a rate of 2,000 times a second. Most theorists predict that ordinary matter would tear itself apart at such a rotation rate. But on page 633 a candidate is proposed that might survive these arduous conditions — a 'strange' star composed of three-flavour quark matter.

Editorial changes

RNA editing, first described in protozoa, has now been observed in plants. In wheat mitochondria some gene sequences containing C residues are 'edited' to U in the RNA. The possibility that this phenomenon may be even more widespread has important implications for the study of gene expression; protein sequences can no longer be predicted from gene sequences with certainty. Pages 660 and 662.

On the rocks

The rate of settlement of marine larvae into the oceans significantly affects adult populations, but the factors controlling it are unclear. On page 641, Thresher *et al.* show that pulses in the settlement of 'Scott's weedfish' in shallow reefs along the coast of southern Australia are invariably preceded by brief peaks of phytoplankton production.

Changing partners

Triggering the antigen-specific T-cell receptor transduces a signal which leads to the increased adhesiveness of the lymphocyte function-associated molecule LFA-1 for its ligand, an intercellular adhesion molecule. This may explain how a T cell is able to sample a large number of potential targets quickly, latch onto those it recognizes, and disengage as soon as its effector functions are done. Page 619.

Soothing news

Fears that the commonly used anaesthetic gases halothane, enflurane and isoflurane will contribute to greenhouse warming or ozone depletion may have been exaggerated, according to results presented on page 635.

RA of newt

The isolation of two retinoic acid receptor genes from the newt suggests that there may be as many as four different types, each of which may separately contribute to the morphogenetic action of retinoic acid. Page 654.

Tunnel vision

Two experiments cast new light on the fundamental character of quantum mechanics. The time spent by a particle under a classical forbidden barrier during a tunnelling event has been measured for the first time, confounding notions that this is an undefinable event, page 567. And the Schrödinger equation has passed the first test in 60 years of its actual form, page 571.

Conservation in protein

Specific residues on the eukaryotic POU protein Oct-1 that allow it to activate transcription by complex formation with the viral protein VP16 are at a position exactly analogous to those that confer the activation function on the bacteriophage lambda repressor protein, suggesting some conservation of function between eukaryotic and prokaryotic transcriptional regulatory proteins. Page 624.

Growing nerves

Real-time observations on developing nerve ensembles in the olfactory bulb of the mouse reveal that the full complement of neural circuits is not present at birth. Instead, discrete units are gradually added to the existing ensembles during early postnatal life. Page 646.

We specialize in quality, custom peptide synthesis . . . so *you* don't have to!

HPLCs of unpurified, HF cleaved peptides

Our proprietary techniques enable MPS to supply you with all the custom peptides you need. For example, we can provide over 100 completely different 15-residue peptides in as little as three weeks. An analytical HPLC chromatogram is included with each peptide ordered.

MPS offers quality peptides with service we're sure you'll like. Call us with your questions or if you would like a complete price list.

MPS also provides a custom HF Cleavage Service and a unique HF Cleavage System.

COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

10mer	**$400**
15mer	**$550**
20mer	**$800**

Prices are based on 50mg of HF Cleaved Peptide. 4 to 6 weeks delivery, minimum order of 3 peptides or $1000.

CAN YOU SYNTHESIZE PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagants, personnel, service contracts, analysis, waste disposal, downtime and, of course, the initial cost of the synthesizer.

FAST TRACK,*™

The Highest Quality mRNA from Cells or Tissue in 4 Hours Flat...

Get The Message

The FAST TRACK mRNA isolation kit will efficiently isolate high yields of intact poly A^+ RNA directly from cells or tissue in less than four hours!

//// Double the Yields of Standard Procedures

//// Combines Speed and Simplicity with Higher Yields of Intact RNA

//// Half the Cost of Other Antiquated Procedures

//// Isolation of mRNA from Small or Large Tissue Samples

//// A Complete Set of Pretested Reagents and a Simple-To-Follow Instruction Manual

The FAST TRACK™ procedure gives you consistently higher yields of active, intact mRNA for the construction of cDNA libraries, primer extension, RNase A protection analysis and Northern blots. FAST TRACK yields 40-100µg of poly A^+ from 10^8 cells or 1 gm of tissue.

Let Invitrogen put you on the FAST TRACK. To order, ask for catalog No. K1593-02 after calling ...

NEW

HORIZONS FOR ELECTROPHORESIS

The innovative Horizon™ 11·14 and 20·25 Electrophoresis Systems from GIBCO BRL are designed to let you cast, run and process high quality agarose gels consistently and conveniently. Set up is virtually effortless with Horizon™ Apparatus.

- There's no need to bother with tape or clamps – just drop the casting dams into their slots and pour your gel.
- Quick connect fittings for buffer recirculation allow you to attach the unit to your lab pump in seconds.
- Both systems feature safety interlock lids and shrouded power cords to maximise user safety.
- The removable UVT tray lets you monitor gels during the run and simplifies gel handling during staining, photography and blotting.
- The units have four adjustable feet allowing you to ensure that your gels are precisely level – even if your bench isn't.

Ancillary products in the GIBCO BRL range include power supplies, blot transfer systems, external gel casting systems and a wide selection of combs.

Thanks for your help!

We asked you, the user of oligonucleotide synthesizers, the producer of oligonucleotides, how we could improve oligonucleotide synthesis for you. The result was Gene Assembler® Plus, our new oligonucleotide synthesizer.

As Easy as A, C, G, T . . .

- **Truly easy software,** making handling, synthesis and maintainace really simple.
- **Preprogrammed optimised synthesis methods,** including custom synthesis and a program for 5'-aminoalkylation.
- **Unique monitoring system,** reporting the success of synthesis with automatic feedback control to interrupt the synthesis if something should go wrong.
- **Automatic documentation,** of sequences and results.
- **PAC amidites for better results.** PAC amidites give a purer product due to less depurination.
- **Faster results,** deprotection with PAC amidites and support takes only 60 minutes.

The concept of Gene Assembler Plus is to make oligonucleotide synthesis easier, to improve performance and results. Thus making it perfect for all oligonucleotide synthesis including PCR primers.

The positive reaction Gene Assembler Plus has received testifies to the contribution you've made.

Why not contact us today and find out more about what Gene Assembler Plus can do for you!

We help you manage biomolecules.

Highest resolution of chromosomal DNA

New CHEF-DR™ II System: A major advance in pulsed field electrophoresis.

Yeast chromosomes, strain YNN 295. 16 chromosomal DNA fragments are resolved. Sizes range from 0.2 to 2.2 megabases.

The CHEF-DR II system* lets you resolve DNAs from 200 bases to 10,000,000 or more[1], with sharp bands. This powerful system integrates advanced micro-electronics and electrophoresis technologies to produce straight lanes and an extraordinarily wide range of size separations.

The CHEF-DR II system is the only system available with electronic feedback clamping of each of the chamber's electrodes. The voltage sensing provides uniform fields in the gel at all times, independent of variations in buffer conductivity, sample placement, gel dimensions, or temperature. Consequently, you obtain all the following benefits:

- Highest resolution
- Straight lanes
- Sharp bands
- High sample capacity, up to 30 lanes
- Widest range of DNA size separation
- Reproducible separations

A lot more than equipment comes with the CHEF-DR II system. The comprehensive instruction manual guides you through sample preparation and electrophoresis. We've also included strategies for separating all sizes of DNA. And we also provide in-depth technical support after you begin your pulsed field experiments.

The CHEF-DR II system can extend your horizons in chromosome analysis, mapping, screening, and DNA sizing. Bulletin 1430 brings you complete details, including a comparison of pulsed field techniques and their respective resolving powers.

*Dynamically Regulated Clamped Homogeneous Electric Fields. Patent applied for.

FULLY PROGRAMMABLE DRI-BLOCK® TEMPERATURE CYCLER PHC-2

This latest programmable Dri-Block® temperature cycler PHC-2 has a powerful microprocessor programming capability yet is designed for simplicity of operation. It is now possible to link programmes, hold temperatures for long periods choose four ramp rates up and down and recall temperatures and times from the PHC-2 memory. Two models are available for use with either 0.5 ml or 1.5 ml microcentrifuge tubes.

- Temperature range 0°C–99°C
- Fast temperature change
- Wide and variable number of segments, programmes and cycles – limited only by memory capacity.
- Four user selectable up/down ramp rates
- 99 hour maximum hold time
- Remote sensor in dummy tube to read sample temperature and initiate programme timing.
- Block uniformity 3°C
- RS232 outlet/centronics printer output
- 54×0.5 ml or 24×1.5 ml microcentrifuge tubes
- Water cooled with separate connection for end of programme below ambient cooling
- Temperatures and times held in memory for recall to screen or printer

PHC–1

For less sophisticated programming requirements the alternative model PHC-1 is a simple to use heat/cool unit providing a repeatable cycle of up to three independent temperatures and dwell times. A standard aluminium block will accept up to 54×0.5 ml capped microcentrifuge tubes.

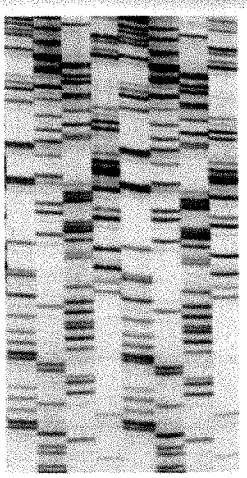
If sequencing has you going around in circles...

let *FASTaq*™ straighten you out.

Introducing the *FASTaq* sequencing biosystem. The first single incubation protocol.

Finally, there's an end to the mix/incubate/cool cycle. With *FASTaq*, you just mix, incubate once and load. *FASTaq* can cut up to half an hour and up to seven steps from your preparation time while leaving less to go wrong. Best of all, you can walk away while its incubating — and use the time to get more things done.



The *Thermus aquaticus* polymerase actively catalyzes polymerization at temperatures exceeding 70°C. These higher temperatures denature virtually all template secondary structures and hairpins that cause most data errors. You get crisp, clear, accurate data every time.

Find out more about the *FASTaq* sequencing biosystem. Call or write today. . .and straighten yourself out.

TS 11725 Film 1 CZ/ICS-Anzeige Photomicrografie englisch (Auftr.-Nr.: 71402983) 2/15.12.1988

For 117 years, Carl Zeiss has been "The Great Name in Optics". The tradition continues with the best microscope optics ever.

FOR THE ULTIMATE PERFORMANCE IN PHOTOMICROGRAPHY. ICS OPTICS FROM CARL ZEISS.

ICS optics (Infinity Color-Corrected System) are an advanced series of newly calculated, highly corrected microscope objectives with infinite image distance. But there is more. ICS optics are integrated into the new series of Zeiss microscopes as fully optimized systems. From the light source to the objectives, eyepieces and camera – everything is in perfect harmony. That is what makes the difference between ICS optics and other optical systems, and what guarantees a new dimension in flawless photomicrography.

You'll be surprised at what you can make visible.

Volvox, darkfield, magnification 100 : 1, Plan-Neofluar 10 x/0.30
Axioskop routine microscope with MC 100 microscope camera

Brilliant photographs – high contrast and high resolution
The Planapochromat and Plan-Neofluar ICS objectives provide excellent image quality in photomicrography. The intermediate image is fully corrected due to the unique Zeiss patented objective and tube lens combination. Sharp, crisp, absolutely flat images over the wide field of view of 25.

Camera projection lenses, corrected for the full spectrum of color films, transfer this high image quality to the film.

90% of light for the film
The fully integrated cameras of the photomicroscopes Axiophot and Axiovert complement the superb performance of the ICS optics. 90% of the light is used on the film. The result: short exposure times, particulary important for fluorescence.

Spot measurement concentrates the exposure on the most important specimen detail. Illuminated reticles, adjustable to the brightness of the background, simplify focusing. Focused-in scale bars facilitate documentation.

For every application in photomicrography, the new series of Zeiss microscopes with ICS optics will surprise even the most demanding microscopists.

With fully integrated camera:
Axiophot® photomicroscope
and
Axiovert® inverted microscopes.

With MC 100 microscope camera:
Axioplan® universal microscope
Axioskop® more-than-routine microscope and
Axiotron® inspection microscope for the semiconductor industry.

LIBRARIES ARE OUR TURF

Track Record is Important. . .

- Over 2,000 genes have been isolated from our libraries
- Hundreds of Custom Libraries have been ordered from CLONTECH since 1984
- 300 Libraries are available from our inventory of human, animal, plant and bacterial libraries

The Latest Vector Strategies . . .

CLONTECH uses the latest vectors, like SWAJ-2, mammalian shuttle vector πH3 and improved EMBL3. Our scientists will assist you in selecting a vector best suited for your needs.

Reader Service No.499

League Leader in Completions . . .

We go to greater lengths, with another CLONTECH 1st: 5'-Stretch™ Libraries — with a greater percentage of full-length cDNAs. These libraries give you a higher probability of locating your complete gene.

All-Pro Effort . . .

At CLONTECH, each scientist never handles more than 2 custom libraries at once, maximizing personal attention and minimizing opportunities for mix-ups. A single person takes your library from start to finish, giving you consistently better results.

Need Assistance?

If you have a limited budget, we can offer you a 50-100% discount on your custom library preparation in return for resale rights. Discounts are based on the demand for a library from any particular tissue.

Ask a Fan . . .

We've been a part of a lot of success stories over the years. Let us supply you with a list of customers in your area who have scored using custom libraries from CLONTECH.

PREM™ SERIES III

THE TECHNOLOGY OF HEAT SEQUENCING

With solid state design, PREM™ offers rapid and precise temperature and time interval control,from 15°C to 105°C, at a rate of approx. 1°C per second - heating and cooling.

Programmable Restriction Enzyme Module

Remote Operation

As PREM can be controlled remotely, your DNA applications may be run within sterile conditions, minimising any sample contamination.

Enhanced Software

PREM's comprehensive software is easy to use. You can select virtually any time duration and if required, sample integrity will be maintained in the refrigerate mode.

Real Time Hard Copy

For real time hard copy of experimental conditions,PREM can be directly linked to a printer. Incubation temperatures, transition times, full programme content and even dates and times will all be printed out automatically as a full record of events.

Integral Versatility

In only a few seconds, PREM can be reformated to use different sized microcentrifuge tubes, or microtitre plates, strips, and other popular sample holders. So any application can be run, at any time.

PREM is ideal for restriction enzyme digestion, preparative work for DNA sequencing analysis, polymerase primer extention, plus numerous other biochemical reactions.

PREM is designed for medical and research scientists, where precision and versatility are paramount in heat sequencing.

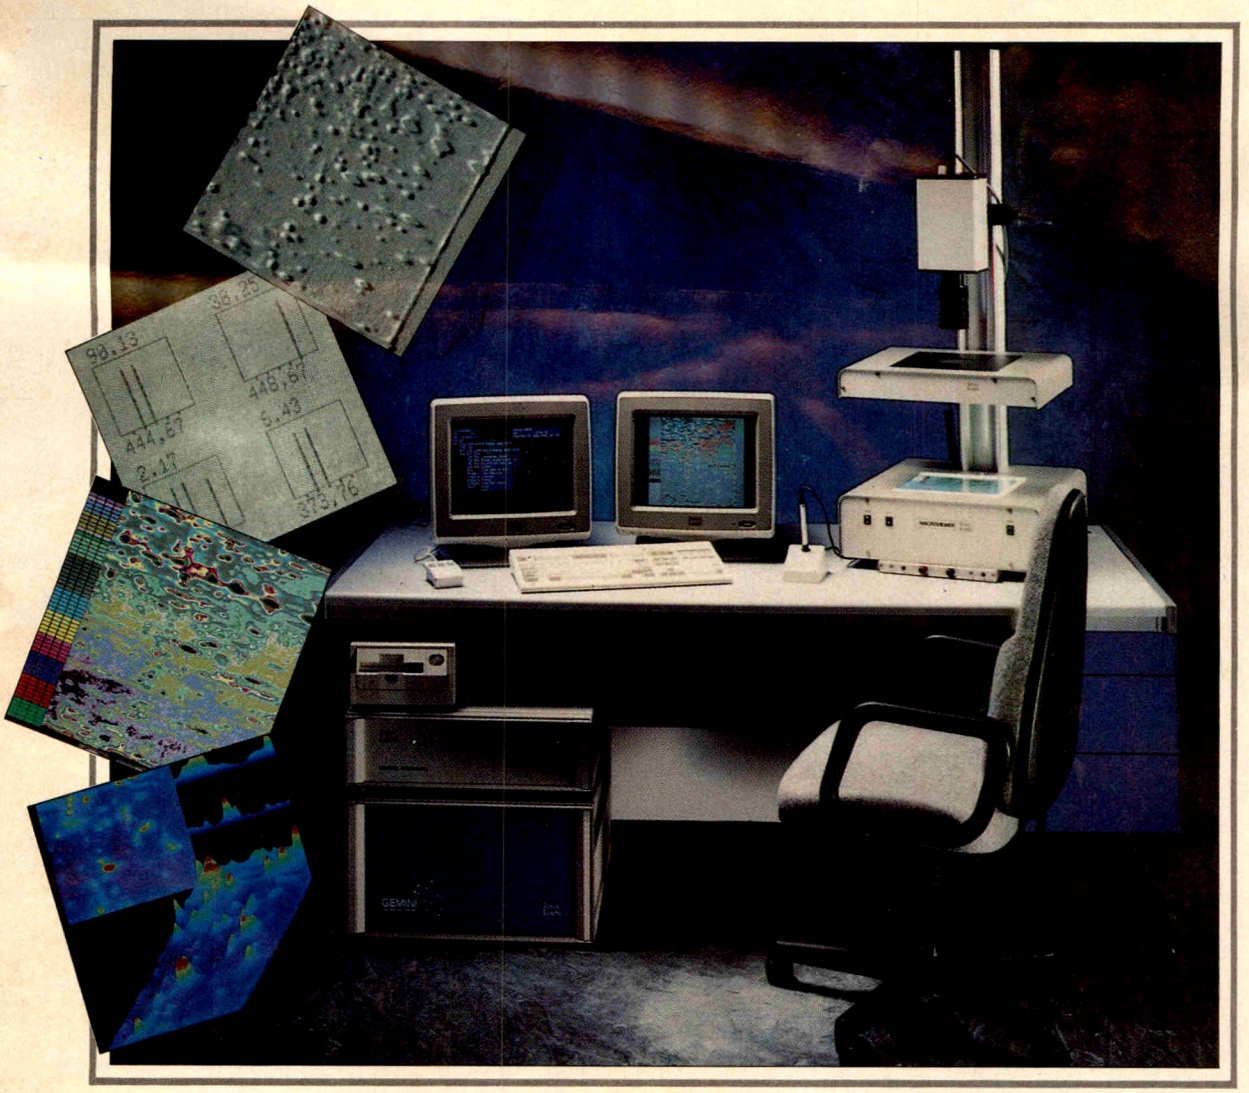
Between these two great universities, renowned for their scientific expertise, is a company with a similar reputation.

Specialising within the field of Biotechnology, LEP Scientific is committed to providing a range of laboratory products ideally suited to the needs of the medical and scientific researcher.

Between Oxford & Cambridge is another faculty for science.

The Biotechnology Division's ongoing research programmes, in collaboration with some of Britain's leading universities, always ensure a high degree of excellence.

From development to distribution, specialist advice, training in product use, and a skilled team of personnel all contribute to what is by any standards, an impressive achievement.



The PREM™, Programmable Restriction Enzyme Module, is the very latest development of the range. Utilising DNA technology PREM is ideal for restriction enzyme digestion preparative work for DNA sequencing analysis polymerase primer extension plus numerous biochemical reactions.

From research probes, restriction enzymes primers and fine chemicals to a custom service synthesising tailor-made genes, peptides and antibodies. The range continues to increase.

With total dedication to research and development, LEP Scientific's Biotechnology Division is continuously striving for tomorrow's answer today.

GEMINI — PROBABLY THE ONLY GEL ANALYSER YOU'LL EVER NEED

Flexible in specification and powerful in analysis, Gemini provides a detailed analytical facility for the study of 1 Dimensional and 2 Dimensional Gels. 1 D gels can be acquired and processed on the system or acquired via a high quality external densitometer. The extensive analytical features include distortion correction, automatic background subtraction, peak spotting, numbering and labelling, track comparison, calibration and report format outputs to printer, database and spreadsheet.
2 D gel analytical capabilities are equally impressive. Features include automatic spot extraction, background correction and spot measurement with powerful vector matching for inter-gel and inter-experiment comparisons. A comprehensive statistical package allows full data interpretation.
All of these benefits make Gemini a most cost effective gel analysis system – probably the only one you'll ever need.

An integrated system of

dedicated high speed hardware

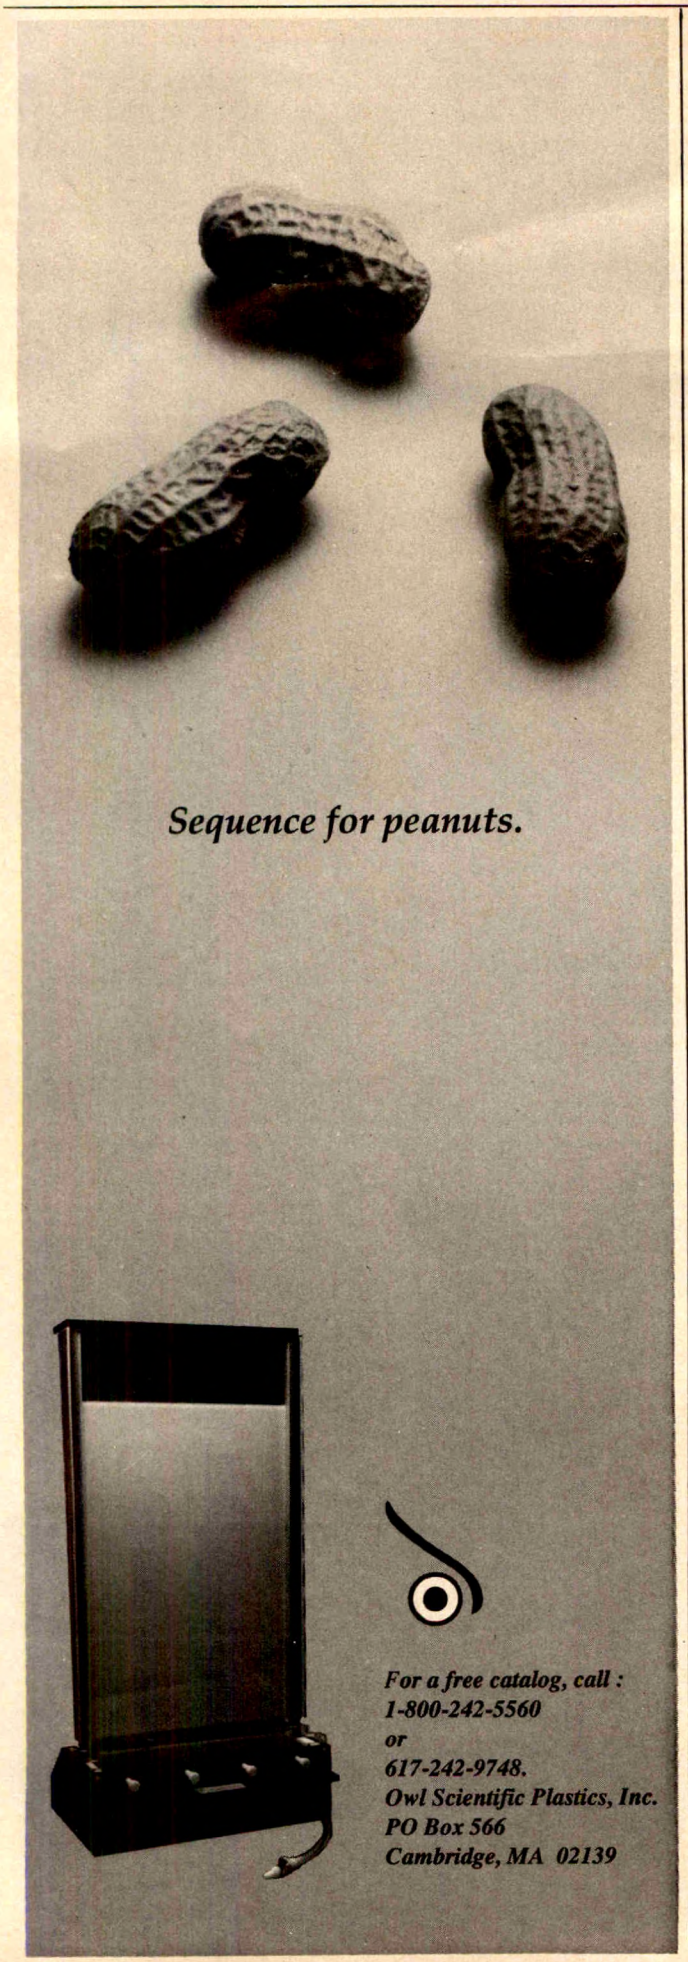
running powerful and flexible

software provides the ideal environment

for the research biochemist and

the molecular biologist

to further the study of



proteins and DNA fragments.

Wall Street's second tumble

Coincidences are usually meaningless, but can it be significant that last Friday's tumble on Wall Street marks almost exactly the second anniversary of the crash on 19 October 1987, a Monday? Magic is no part of the explanation.

On the assumption that the failure of two US banks to raise the loans required to pay part of the purchase price for United Airlines was the occasion for, but not the cause of, last Friday's sudden collapse on Wall Street, the belief that October is a dangerous time of the year is bound to gain currency. But what can be the explanation? That October marks the beginning of the US government's fiscal year may not be entirely irrelevant, for it is about now each year that the United States usually discovers that the administration and the Congress have reached an unsatisfactory compromise on spending for the year ahead. This year, of course, there is no compromise, but President Bush will have to announce that all discretionary elements of federal spending (including research support) will have to be reduced by roughly 1.5 per cent. This decision, also reached last Friday, can hardly have inspired confidence in Wall Street, or anywhere else.

What else of significance can there be? In 1987, as this year, the International Monetary Fund had just met in Washington, uttering a largely cheerful prognosis for the years ahead. Then, as this year, the fragility of the world's financial system engendered by the $300,000 millions of debts owed by developing countries was underplayed, which is hardly a confidence-building measure. In a separate meeting, the finance ministers and central bankers of the seven important industrialized countries, in 1987 as this year, offered a comforting account of the progress of the world's economy. If the bankers, who should know best, fail to recognize the fragility of the markets, how can the traders who live in them go about their business confidently? If these financial institutions cannot change their ways, they might at least change the season of their meetings, say to the northern spring, so that it will be possible for the rest of us to judge empirically the extent to which their persisting blandness scares the money people out of their wits.

But it is pointless to search for an explanation of coincidence when the causes of last week's tumble are persistent and plain. Since the beginning of this year, there has been a steady trickle of depressing news about the market in junk bonds — the financial instruments which have flourished in the past few years and which, unlike other bonds, are secured not on tangible assets but on the future income of a company. By means of junk bonds, almost anybody can set out to buy virtually any publicly quoted company; it is simply necessary to sell enough debt to cover the purchase price. In practice, the owners of a company will usually not sell unless they are offered some cash along with the junk.

If things go well, the purchaser can hope to make a profit by selling off pieces of his purchase, while the holders of the junk bonds enjoy the high interest appropriate to risky investments. Sadly, for some of them, if things do not go well, everybody catches cold. The largest casualty this year is the Canadian company called Campeau, which bought a chain of US retail stores with $10,000 million of junk bonds and then found, two months ago, that it could not pay the interest to which it is commited and also fill its shops with goods for the Christmas spending season. The spectre Wall Street's traders glimpsed last Friday was that of the decimation of this huge amount of debt, comparable in amount with the $300,000 million the poor countries of the world owe their creditor banks. The trouble about United Airlines was that banks were unwilling to provide the cash that would earlier have been provided by the junk bond market if it had not dried up.

So what, it may be tempting to ask; what does it matter if financial speculators lose their shirts from time to time? One answer is that it is not their money, but, in some sense or another, ours. The financial institutions that keep the stock markets alive are mostly the repositories, in the industrialized countries of the West, of ordinary people's savings. Second, the steps that governments will now be compelled to take to remedy the effects of the crash that began on Friday are bound to hurt. In the United States, for example, it seems increasingly unlikely that President Bush will be able to hold to his declaration that taxes will not be increased. The central bank (the Federal Reserve) will be compelled to reduce interest rates to combat the deflationary effect of the tumble, increasing the difficulty of tempting people to cover the federal deficit with their savings. In Britain, for much the same reasons, it is less and less likely that the government will be able to continue pretending that the pound sterling is worth almost exactly 3.0 deutschmarks, and that may be no bad thing, but one consequence is that inflation will be increased.

These events will also exacerbate the long-standing distrust of the financial communities by industry, forever complaining that people are more ready to invest in funny financial instruments than in productive assets. Often, the

complaint is self-serving, the defence of inefficient management. But what this second tumble on Wall Street shows is that the short-term calculations of the financial communities that there is more profit in the junk bond market and other expedients for making money than in industrial investment are somehow mistaken. The West being what it is, the only long-term remedy must be to provide incentives for productive industrial investment. Then, there would be more financial securities to soak up people's savings, so that stock market prices would settle at more realistically low levels, while interest rates would decline with people's expectations of what constitutes a sustainable return on their investments. But that halcyon dream is separated from the present by the huge uncertainties of the weeks that lie ahead. □

Agricultural contest

The US Department of Agriculture should respond to a plea to fund research competitively, but with guille.

ALTHOUGH it is high time that an influential body such as the National Research Council (NRC) complained that the US Department of Agriculture (USDA) should spend its research funds more intelligently (see page 561), it should not be surprised if its arguments fail to be reflected in the shape of the federal budget. There have been some occasions in the past forty years when the department itself has been persuaded that it should change its ways, these have never coincided decisively with occasions when the Congress is prepared to sanction change. The stumbling-block is always that the Congress, but sometimes also USDA itself, seems to be persuaded that spending more on competitive research grants would be the death of the traditional way of of channelling funds to US universities — the hallowed but often abused system of land-grant colleges.

It need not be like that at all. The land-grant system, originally a scheme for stiffening the agricultural extension services intellectually, is rightly respected throughout the world. The original calculation was that the generous endowment of agriculture and related departments at universities, and the creation of links with federal and state extension services, would give the United States a productive and resilient agricultural economy. No disrespect of USDA's own research establishments is implied by the acknowledgement that the original calculations were accurate. US agriculture is indeed the most productive in the world.

That is the good news. The other side of the coin is that times have changed and that, among the agricultural establishments of the land-grant colleges, some have turned out to be better than others. While nobody can fault, for example, the University of California at Davis for its eagerness to seize on new techniques such as those suggested by molecular biology, others are still rather woodenly concerned with the applied research that used to be their staple diet, but which is increasingly irrelevant to the needs of US agriculture. It is especially galling that many of the sleepy but rich places live alongside people in other than agricultural departments who have to fight their way into the competitive world of modern biology through the eyes of all the needles that make up the competitive grants business administered by the NIH.

What NRC asks is that there should be an extra $500 million — more than ten times present spending — for a new programme of competitive grants in agriculture. Its calculation that the investment would pay off is probably correct. The practical and political problem is whether the new programme could be introduced in such a way that the old agricultural establishments would not be left entirely out in the cold; otherwise, there is an eager band of congressmen ready to leap to their defence. Tactically, this requires some kind of understanding between university presidents and USDA on how to revivify the places now asleep. □

Paying academics

British university teachers are ill-paid, but their new salary claim should be more subtle.

THE British university teachers' union, the Association of University Teachers (AUT), resolved at the week-end to ask for a 27 per cent salary increase. In equity, the claim is undeniable. Indeed, the erosion of university teachers' salaries by comparison with those their graduates quickly earn has been so rapid that it is surprising that the claim is so relatively modest. One difficulty is that their employers cannot afford to meet the claim; any extra funds will have to be provided by the government as part of its general subvention of the universities. Another is that university teachers will undermine a good case if they again engage, as threatened, in a boycott of university examinations or some other such unprofessional protest. A third, is that the present system of national bargaining on university salaries is an anachronism

There are good tactical reasons why AUT as such cannot confess that the time has come when teachers at one university should not expect to be paid what those at another earn; to concede that at the outset of what must be a bruising negotiation (from which the real paymaster will be absent) would evidently undermine AUT's case. But entirely to deny the likelihood that there will eventually be a time when universities compete for teachers, and when the stronger get the best, is unrealistic.

Paradoxically, it could be in the best interests of most teachers at British universities that national agreements should be abandoned. Already, there is resentment in the universities that teachers at British polytechnics are better paid. But just as national salary scales are in the long run untenable, so is the division between universities and polytechnics. Universities (and academics) being what they are, it would not be in the least surprising that, when the system settles down, Oxbridge salaries will be less than at the University of the Stix. □

Is the end of particle proliferation at hand?

■ Only three particle families exist
■ Rubbia accuses SLAC of sharp practice

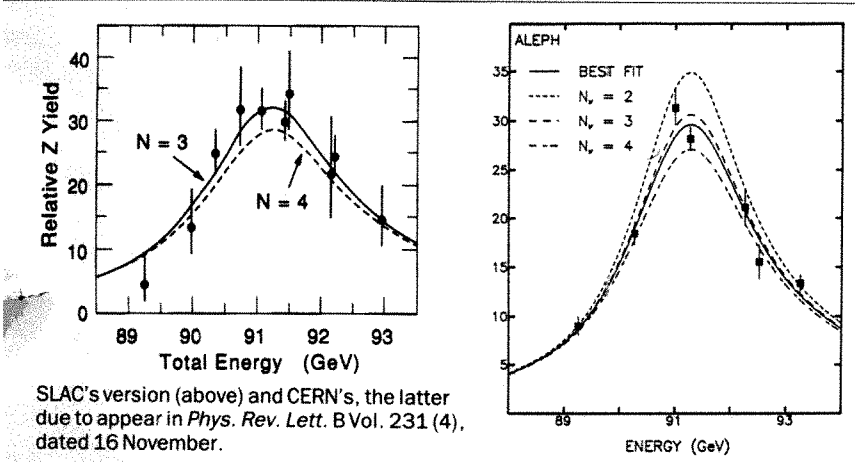
London & Washington

In parallel announcements from the Stanford Linear Accelerator Center (SLAC) in California and the European Particle Physics Laboratory, CERN, in Geneva, physicists proclaimed last week that they had put a limit on the number of 'families' of elementary particles.

The two laboratories, which house the world's principal positron–electron colliders, had been engaged in an informal race to establish the new result, but CERN's director, Carlo Rubbia, has accused SLAC of using "hockey player's tactics" and of "scraping the bottom of the barrel" in making an announcement that beat CERN's by one day.

But Burton Richter, director of SLAC, says there was no contrivance in the near simultaneous declarations, and denies that his team went to any unusual lengths to "dig things out of the data" prematurely.

Both the Stanford Linear Collider (SLC) at SLAC and the Large Electron–Positron Collider (LEP) at CERN were designed as Z^0 "factories" in which electron–positron collisions would create quantities of the Z^0 particle, a crucial ingredient of particle physics for the discovery of which Rubbia won the Nobel prize in 1984.



SLC, a technically complex adaptation of an existing machine, has had some difficulties reaching its design performance (*Nature* **340**, 587; 1989). LEP, by contrast, is a traditional circular synchrotron, and has come up to design specification only weeks after being switched on.

In the race to get big physics results, SLC got an early start, but LEP, by virtue of its higher beam energy, has produced more than 11,000 Z^0 particles in just 15 days, compared to 500 in 6 months of experiments at SLC. This mass-production has an important purpose. The known elementary particles, quarks and leptons, fall into three families or generations: each family includes two quarks, a heavy lepton, (the electron, muon or tauon) and the corresponding neutrino. The third family awaits the discovery of the top quark, but otherwise the picture is complete. But there has been some doubt whether there might not be one or more undiscovered families, and the lack of a clear answer has impeded theoretical understanding.

From the rate of production of Z^0s over a range of collision energies, it is possible to deduce the number of families: the greater the number, the more ways there are to make Z^0s and the greater is the "width" of the Z^0 — its production rate as a function of energy.

The new data from both CERN and SLAC show conclusively that three families is all there are, but this harmonious conclusion has been marred by Rubbia's allegations about last Thursday's press announcement from SLAC. CERN announced an identical conclusion, based on a greater volume of data, the next day.

Speaking at a conference in Pisa at the weekend, Rubbia was evidently irritated at the order of the announcements, and sought to put the US group in what he regarded as its proper place. According to a report in the Italian newspaper *La Republica*, he said that "at best the Americans will confirm our data, coming in second place — a position they will never accept". The complaint is that SLC physicists knew of CERN's intention to announce the new LEP results last Friday and decided to scoop the Europeans by issuing the Stanford data a day earlier.

SLAC's version (above) and CERN's, the latter due to appear in *Phys. Rev. Lett.* B Vol. 231 (4), dated 16 November.

IVORY TRADE

African dissent at two-year ban

Paris

After a week of debates, delegates at the seventh conference at Lausanne of the parties of the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES) voted late on Monday to move the African elephant to Appendix 1 of the convention for two years. This in effect, means a blanket ban in trade in ivory from the African elephant. But nine African nations voted against the proposal, and five are to apply to enter a reservation which could mean that the ban will not apply to them.

The CITES decision has not pleased some African nations, such as Zimbabwe, who say that ivory trade is necessary for their economy and to control growing populations of elephant. Zimbabwe has developed a model practice for management of elephant culls and says that a ban will make it difficult to continue to make the policy work. But the CITES ban allows African nations to reapply for a licence to export ivory if, after two years, they can show that they have developed an effective strategy to prevent further decline in their elephant populations.

Over the past nine years, the population of elephants in Africa has declined from an estimated 1.3 million to around 600,000. According to some estimates more than 90 per cent of ivory leaving Africa is from animals killed by poachers. Peter Coles

Richter, although hesitant to respond to newspaper reports of what Rubbia had said, denied there had been any attempt to steal CERN's thunder.

SLAC, he said, has been releasing progress reports on its work, and at the beginning of August had enough data to put a preliminary limit of 3.0 ± 0.9 on the number of families, which excludes the existence of four families with a confidence level of about 70 per cent. By the beginning of September, a better limit of 2.7 ± 0.7 had been obtained, excluding four with a confidence level of 96 per cent. This was announced at a meeting of the European Physical Society in Madrid. Then two weeks ago, a paper with this conclusion was submitted to *Physical Review Letters*, a press announcement was made and copies of the paper were faxed to, among other places, CERN.

Not everyone at CERN shares Rubbia's anger. Indeed, many feel that the scramble for press publicity, which seems to be a consequence of the struggle to find money for new accelerators, in the end does a disservice to high-energy physics by provoking public quarrels. Even Rubbia confessed that the race to find the elementary structure of matter is becoming "a soap opera — like Dallas".

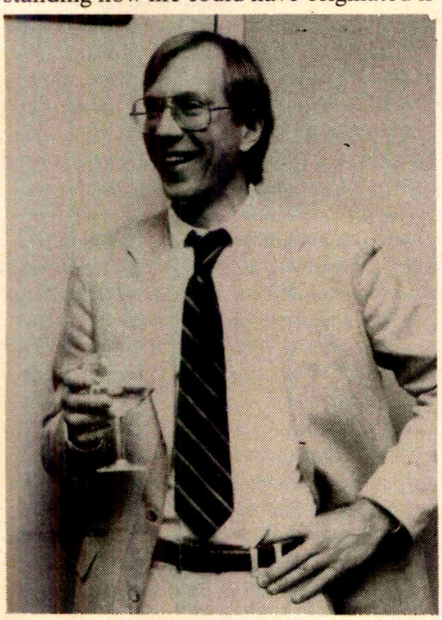
NOBEL PRIZES: CHEMISTRY

RNA's catalytic role

London

THIS year's Nobel prize for chemistry has been awarded jointly to Sidney Altman of Yale University and Thomas Cech of the University of Colorado, Boulder, for their independent discoveries that RNA can have catalytic activity. These discoveries may have profound implications for our understanding of the origin of life, and may also lead to important practical developments.



Biological catalysis had previously been considered the exclusive domain of protein enzymes. RNA is usually thought of as a passive informational molecule, though specific RNA molecules have long been known to have non-informational roles in protein synthesis.
